MR. PRESIDENT AND GENTLEMEN,—Like all other hysterical symptoms, each of the five classes of hysterical anæsthesia which I have described in my first lecture is the result of suggestion. In the first class, the classical form which has alone been recognised in the past, the idea that a certain area of skin is insensitive to tactile, thermal, and painful stimuli, is in the first instance unconsciously suggested to the patient by the physician who examines him. The second class, the anæsthesia which may follow a condition of stupor, is also due to hetero-suggestion, although it is preceded by anæsthesia which is neither due to organic disease nor to suggestion, but is the result of profound inattention during the stuporose period. In the remaining classes the anæsthesia is primarily organic in origin, being caused by disease or injury of the brain, spinal cord, or peripheral nerves, or by peripheral anæmia. It makes so great an impression on the patient's mind that it is perpetuated as an hysterical symptom after the organic cause has disappeared. This is, no doubt, in part a result of auto-suggestion, but it is clear that such auto-suggestion would very rarely occur if not prompted by a certain amount of unconscious hetero-suggestion on the part of the physician, whose interest in the anæsthesia attracts the patient's attention to what would otherwise be to a great extent ignored owing to the small inconvenience the anæsthesia causes compared with the associated paralysis. So impressed was Babinski¹ with the part taken by the observer in suggesting hysterical anæsthesia that he expressed his belief that the condition never occurred in the absence of such suggestion. Whilst I agree with him so far as the first class of hysterical anæsthesia is concerned, I have certainly seen cases of the third class—that caused by injury to peripheral nerves, and possibly in the fourth and fifth classes, in which any such hetero-suggestion could be excluded with certainty. Although in most of these cases hetero-suggestion undoubtedly plays the predominating part, auto-suggestion generally occurs as well, and in rare cases it is alone responsible for the production of the anæsthesia.

The next question to discuss is by what process anæsthesia develops when it has once been suggested by hetero-suggestion, auto-suggestion, or the two combined. I believe that a consideration of the second class of hysterical anæsthesia, that following stupor, affords the only satisfactory explanation. In order to feel one has to pay attention. If the whole mind is absorbed with one's thoughts, tactile and other cutaneous stimuli will not be felt. Most healthy people are aware of this from their own experience. If one is intensely interested in the occupation in which one is engaged a light touch will not be perceived, or the discomfort caused by external heat or cold or by some form of cutaneous irritation will not be felt until the mind is once more free to attend to such mundane affairs. The importance of this conception can only be fully realised by those who have had the opportunity of examining cases of stupor, such as I have described as occurring in the over-wrought soldier. The patient's mind was obviously absorbed in the contemplation of his own thoughts, which were generally painful in character, and were often so vivid that they could be correctly described as visual or auditory hallucinations.

* Lecture I. was published in THE LANCET, July 24th, 1920 (p. 16).

Tickling the face or the soles of the feet, pinching or pricking the most sensitive parts of the skin, or the application of very hot or very cold objects failed to elicit the slightest sign indicating that the individual had felt anything. The conjunctiva, cornea, and nasal mucous membranes were equally insensitive, and all superficial reflexes were abolished. Inattention had resulted in anaesthesia.

When an individual accepts the suggestion that he cannot feel over a certain area of skin he withdraws his attention from this area, and he consequently no longer feels any stimuli applied to it. This conception will be more fully discussed later, when I shall show how hysterical blindness may result from not looking, as without looking it is impossible to see, and how hysterical deafness may result from not listening, as without listening it is impossible to hear. For feeling, seeing, and hearing are active processes, and require an effort of the will just as much as walking. The latter becomes automatic in process of time, but if an individual accepts the suggestion that he cannot walk, he no longer makes the active effort which is required. Without this no walking can occur, however automatic the movement may appear to be in a healthy individual. In the same way, if an individual accepts the suggestion that he cannot feel, see, or hear, he ceases to make the active effort involved in the process of attention to cutaneous, visual, or auditory impulses. To a normal man feeling, seeing, and hearing appear to be the result of cutaneous, visual, and auditory stimuli, respectively acting upon the skin, eyes, and ears; but this is only true if he is actually attending, although this active attention is as little a conscious process as the performance of the individual movements in walking.

A study of the behaviour of the cutaneous reflexes in hysteria will show that an anatomical basis for hysterical anaesthesia must exist, which depends upon the removal of the structural foundation of the psychological process of attention. A reflex is the automatic response to a peripheral stimulus, and is entirely independent of consciousness. It is thus inconceivable that a reflex could be abolished unless some alteration had occurred in the structures which control the reflex arc. The abolition of a cutaneous reflex in organic disease, is, for example, regarded as a proof of the existence of a lesion interfering with these structures. Apart from the abolition of the plantar reflex, when the feet have become cold owing to the feeble circulation caused by disuse in hysterical paraplegia, superficial reflexes are only diminished in activity or entirely abolished in hysteria in the rare cases of hysterical anaesthesia in which sensibility is almost or completely absent. In the exceptional cases of total anaesthesia the corresponding superficial reflexes are lost, just as all superficial reflexes are lost in the total anaesthesia present in severe stupor. Recovery from total hysterical anaesthesia, either spontaneously or as a result of treatment, is accompanied by a return of the superficial reflexes, just as they return when a condition of stupor passes away.

The simplest explanation of the behaviour of the superficial reflexes in hysterical anaesthesia is that the structural basis of the psychological act of attention consists in some change which leads to a diminution in the resistance offered at each synapsis of the sensory tract. Perhaps this is in the nature of throwing out of dendrites, or it may depend upon some biochemical change in the material which occupies the space between the dendritic terminations of adjacent neurones. Whatever it may be, the increased resistance which is present when attention is very deficient results in anaesthesia, and at the same time a block is produced in the reflex arc which results in diminution or abolition of the reflex.

The usual method of treating hysterical anaesthesia by means of a strong faradic current depends upon the fact that the anaesthesia, however severe, is very rarely absolute. A very powerful stimulus, such as that afforded by a strong faradic current applied with a wire brush, can break through the increased resistance at the synapses in the sensory tract in spite of the almost complete inattention which is present; it is consequently felt. Directly this occurs the patient's dormant attention is awakened; with a little persuasion and perhaps some explanatory conversation, which may be looked upon as acting, at any rate in part, as a counter-suggestion to the original suggestion of anaesthesia, the patient is quickly brought to attend to the stimuli affecting the previously anaesthetic areas of his skin, and normal sensibility returns.

If the anaesthesia is absolute this method cannot be used, as, however strong the painful stimulus may be, it will not be felt. In such a case it may be suggested to the patient that the faradisation of the skin at the boundary of the anaesthetic area will lead to the progressive retraction of this area. The most satisfactory method, however, is to use no suggestion at all, but to explain to the patient why he cannot feel—that he has become accustomed to pay no attention to stimuli

affecting the anaesthetic area, but that if he will concentrate his attention on this area sensation will return. When the individual understands what he has to do, recovery of normal sensibility at once returns, and with the return of normal attention the abnormal resistance at the synapses disappears and the abolished cutaneous reflexes reappear.

THE SUPERFICIAL REFLEXES IN HYSTERIA.

There has been much controversy about the behaviour of the superficial reflexes in hysteria. Differences of opinion are in part due to insufficient knowledge as to the normal variations in the reflex under different physical conditions. My investigation on these subjects have been made principally in connexion with the abdominal reflex, but I shall also refer to some observations on the plantar reflex.

The Abdominal Reflex.

Authorities differ as to the frequency with which the abdominal reflex may be absent in normal individuals. A recent investigation by Söderbergh³ on 700 normal individuals between the ages of 2 and 68 shows, however, that in favourable conditions it can almost invariably be obtained. It is important to adopt a proper method of examination before concluding that it is absent. It is particularly difficult to detect in individuals with much subcutaneous fat or flabby abdominal muscles. It is necessary to watch both for visible muscular contraction and for displacement of the umbilicus or middle line. The epigastric, upper, middle, and lower abdominal reflexes should be successively tested. The skin is lightly and rapidly stroked, and care is taken to observe the response to the first stimulus, as in many cases the reflex rapidly disappears on repetition. As the cause of this disappearance does not seem to have been investigated, I recently carried out some observations, with the help of Dr. W. Johnson and Dr. E. J. Wood, in order to determine the effect of varying physical conditions on the abdominal reflex in normal men.

The first problem to decide was whether the diminution in strength of the reflex on repetition is, as is generally supposed, the result of fatigue or whether it is due to some accidental coincident condition, such as the cooling of the skin which must follow exposure to the air. The latter proved to be the more important factor. In a man who showed an unusually brisk reflex when his abdomen was first exposed no reflex could be obtained after an interval of five minutes, the surface temperature of the skin having fallen from 33.6° to 31° C. in the interval. In a second case the skin on the left side of the abdomen only was exposed; measuring the reflex on a numerical basis from 0 to a maximum response of 6, it was found when tested at intervals of a minute to fall gradually from 3 to 1 at the end of the eighth minute, the surface temperature having fallen from 33.5° to 28° C. On now exposing the whole abdomen the reflex on the right side was found to be still 3 and the temperature 33.5° C.

The effect of the temperature of the skin was confirmed by comparing the reflex obtained on the two sides after one had been artificially warmed or cooled. The warmer side always had the brisker reflex. When the temperature of the two sides became gradually more equal as a result of exposure, the reflexes also became more nearly equal. Some inequality was still observed in one case with a difference of surface temperature as small as 1° C., though when it had fallen to 0.4° C. the reflexes were equal, but in another no definite difference could be seen after the temperature of the skin on the side which had been cooled had risen to within 2.5° C. of the other.

It is clear from these experiments that no accurate observations as to the effect of fatigue can be made until the temperature of the skin has fallen to a constant level, as otherwise it would be impossible to separate the effect of cooling from that of fatigue. When the temperature is constant we found that fatigue is only of importance if the skin is stimulated along exactly the same line on each occasion. If care is taken to stimulate different lines on each occasion there is no fatigue effect, however near the lines may be. But in the former case the effect of fatigue is very obvious.

In one experiment the temperature and reflex having fallen as a result of exposure from 35° to 30° C., and from 6 to 4 respectively, and then remained perfectly constant for a quarter of an hour, the reflex completely disappeared at the thirty-seventh stroke repeated along a line 2½ inches

long in a period of 35 seconds. The reflex was, however, still as brisk as ever when tested on a line of equal length half an inch away on each side. It is clear, therefore, that the fatigue takes place in the peripheral sense organs and not in the reflex centre in the spinal cord. Although the effect of fall of temperature is always well marked, that due to fatigue may be very slight or even absent. Thus in one experiment no diminution in the response occurred after 35 repetitions along exactly the same line in the course of a minute.

The condition of the bladder was found to exert an unexpected influence on the reflex. In a boy whose bladder was filled to an extent that made him desire to micturate no abdominal reflex could be obtained, but directly he had passed 8 oz. of urine a brisk reflex was obtained.

In rare instances we observed variations in the reflex which we could not explain; thus a previously brisk reflex was occasionally found to have almost or completely disappeared after a short interval, though there had been no exposure and the bladder was empty.

Inequality of the reflexes on the two sides of the abdomen is often regarded as evidence of organic disease. But before any conclusion can be drawn it is clear that care must be taken to ascertain whether the surface temperature is approximately equal on the two sides. A patient who had been lying on one side with the lower side in contact with a hot bottle, or one in whom the bedclothes had been carelessly raised during the examination so as at first to expose one side only, would certainly have unequal abdominal reflexes, which might easily be regarded as of pathological significance, though really due to nothing more than the unequal temperature of the skin on the two sides.

Strümpell and Oppenheim regard the loss of the reflex as a valuable sign in early disseminated sclerosis; its almost constant presence in normal individuals makes its absence in doubtful cases distinctly important, but only as a confirmatory sign, as it is very rarely lost before other more conclusive evidence of lateral column disease, especially an extensor plantar reflex, is present. In a series of 50 cases of disseminated sclerosis examined with Dr. Johnson at Guy's Hospital in 1912,⁴ we found that it was absent in 80 per cent., the plantar reflex being extensor in 82 per cent. on both sides and in 4 per cent. additional cases on one side. In future it will be advisable to warm the skin over the abdomen with a hot bottle, and to see that the bladder is empty before concluding that the abdominal reflexes are really abolished.

As in rare cases it is impossible to obtain one or both of the abdominal reflexes although the plantar reflexes are normal, it is very important to know whether the reflexes can be lost or become unequal in hysteria. Babinski has laid it down as a definite law that hysteria never leads to any alteration in the cutaneous or deep reflexes, and the majority of authors agree with him. Thus Williamson has recently emphasised the fact that the reflexes are never affected in hysteria as an aid in diagnosing hysterical from organic anaesthesia. A few writers have, however, expressed doubt on the question, and the following clinical and experimental observations prove conclusively that under certain conditions the abdominal reflexes may be unequal or lost in hysteria.

I have already described the case of Pte. M., the patient who had for nearly two years such complete anaesthesia and analgesia of his skin that no stimulus of any kind, including the strongest faradic current, produced the slightest sensation. The tone of the abdominal muscles was good, the patient was thin, and examinations were made repeatedly over a period of many months under varying conditions, but no abdominal reflex was ever obtained. When at last the patient began to use his left hand an attempt was made to restore sensation on the left side of his body by the application of a very strong faradic current with a wire brush. After several futile attempts the patient could at length just feel the stimulus on the left side, but the right side was still totally anaesthetic, and no smaller stimulus produced any sensation on the left side. The same day a definite abdominal reflex was for the first time obtained on the left side, but not on the right side. As sensibility gradually improved the left abdominal reflex became brisker. After several weeks had elapsed, the patient being now able to walk, cutaneous sensibility over the whole body very gradually reappeared without any special treatment. The right abdominal reflex was now obtainable, but it was very much weaker than the left, corresponding with the greater degree of anaesthesia.

We have thus in a single case an example of hysterical anaesthesia associated at one stage with complete bilateral loss of abdominal reflexes and at another with marked inequality of the reflexes of the two sides.

In 1907² I made several observations on anaesthesia, purposely induced by suggestion in the waking state on patients suffering from hysterical paralysis. In a few cases I succeeded in producing a very profound hemianaesthesia on the paralysed side, and in these cases the abdominal reflex on

the anaesthetic side was weaker than on the other side, and occasionally it was lost, although at the beginning of the experiment the reflexes were normal. When as a result of counter-suggestion the anaesthesia disappeared the reflex reappeared.

In these investigations a change in the reflex was only observed when the anaesthesia was very profound, and, corresponding with this, in the only case of hysteria I have seen in which the abdominal reflexes were affected when the patient first came under my observation, the anaesthesia was complete.

The Plantar Reflex.

The plantar reflex is affected by temperature in exactly the same way as the abdominal reflex, but as the feet are more liable to become cold than the skin over the abdomen the influence of temperature is of still greater importance. It is well known that absence of the plantar reflex is most commonly due to cold, and that a reflex which cannot be elicited at first may be obtained with more or less ease after restoring the circulation by exercise or the application of warmth. By noting the surface temperature we found that as it steadily fell on exposure the reflex became less brisk and finally disappeared. A very slight fall of surface temperature may be sufficient to produce a remarkable alteration in reflex activity; thus a moderately brisk reflex, tested at intervals of 60 seconds, became gradually weaker, and finally disappeared at the end of the fifth minute, the surface temperature having fallen only 2°—from 28° to 26° C.

The diminution and loss of the reflex occurs *pari passu* with the diminution in cutaneous sensibility, which is produced, as I have already pointed out, by the peripheral anaemia, caused by cold. The loss of the reflex is clearly due to the deficiency of the afferent impulses from the skin, which, under normal conditions, give rise simultaneously to the sensation of touch and to the plantar reflex. Apart from the cold feet from which healthy individuals suffer, the disuse resulting from paralysis, whether organic or hysterical in nature, is accompanied by diminished circulation and consequent cooling of the surface, with loss of the plantar reflex.

In the case I have already described of universal hysterical anaesthesia following stupor the plantar reflexes were, like all the other superficial reflexes, absent. On two occasions I exposed the patient's feet while he was asleep. Stroking the soles produced a brisk reflex, and he woke up at the same moment, having apparently felt the touch in his sleep. The return of sensibility in sleep was thus accompanied by return of the corresponding reflex. Immediately afterwards it was found that complete anaesthesia had returned and no reflex could be obtained. When many months later he recovered from his paraplegia the anaesthesia slowly but spontaneously disappeared, and at the same time the reflexes could once more be elicited.

It is clear, therefore, that profound hysterical anaesthesia of the sole of the foot may be accompanied by loss of the plantar reflex. This is quite independent of any change in the surface temperature, and must therefore be distinguished from the much more common loss of the plantar reflex caused by the coldness of the feet in hysterical paraplegia. In the absence of profound hysterical anaesthesia the reflex in these cases returns on warming the feet, just as it does in organic paraplegia if it cannot at first be obtained.

SENSIBILITY OF MUCOUS MEMBRANES.

(a) Conjunctival and Corneal Anaesthesia and Reflexes.

In a later lecture I shall refer to the historical case of Madame Staptart, who was cured of hysterical blindness of ten years' duration by a supposed miracle in 1728. The contemporary description of her case shows that the blindness which affected her left eye was accompanied by complete anaesthesia of the cornea, conjunctiva, and eyelids, with loss of the corneal and conjunctival reflexes, as the finger could be inserted between the lids without producing any sensation or movement. Directly she was cured sensibility returned together with the associated reflexes.

A similar anaesthesia was described by Charcot and others in association with hysterical blindness and more frequently with unilateral narrowing of the field of vision, the whole being part of a more or less complete hemi-anaesthesia. But none of the numerous patients with hysterical blindness whom I observed during the war complained spontaneously of any loss of sensibility of the eyeball or eyelids, and none showed any evidence of the inflammation which is liable to follow injury of an eye which has become anaesthetic as the result of an organic lesion, such as follows the treatment of

trigeminal neuralgia by injections of alcohol or removal of the Gasserian ganglion. In a small number of my cases, however, anaesthesia was discovered on careful examination. I believe that in these cases the anaesthesia was produced by unconscious suggestion on the part of the observer, as when great care was taken to avoid any possibility of this, no anaesthesia was found. A patient with one blind eye is likely to think that the eyeball will also be insensitive to touch if his attention is drawn to the subject, and he will probably include the eyelids in his conception of the eye as a whole, so that they too will become anaesthetic.

In every case in which I have observed hysterical anaesthesia of the conjunctiva and cornea, the corresponding reflexes have been absent and have returned with recovery of sensibility, the association being of exactly the same nature as that observed between cutaneous anaesthesia and loss of reflexes.

In the case of universal and absolute cutaneous anaesthesia following stupor, which I have already described, there was total loss of sensibility of the cornea and conjunctiva of both sides, although central vision at any rate was not affected. This case afforded a good opportunity of watching over a long period the slow restoration of sensibility and of corneal and conjunctival reflexes occurring *pari passu*.

(b) Pharyngeal Anaesthesia.

Pharyngeal anaesthesia appears to have been first described as a symptom of hysteria in 1872 by Anstie.⁵ "Anaesthesia is very often found when looked for," he wrote, "in one situation where its presence is highly characteristic—the back of the pharynx. If a patient, not taking bromide, can, without retching, let you pass the finger well down to the epiglottis, the diagnosis of

reports on war neuroses as an indication of their hysterical nature. It is clear, therefore, that the time has come to decide what value can be placed upon this supposed stigma of hysteria.

With the aid of Captain E. A. Peters and Major J. L. M. Symms, I⁶ first drew up a scale of pharyngeal sensibility, beginning with 0, which indicates complete anaesthesia, and 1, which indicates deficient sensibility and absence of all pharyngeal reflexes, and passing up to 7, which indicates such an extreme degree of hyperaesthesia and such violent reflex spasms that it is quite impossible to examine the throat. After a few days' practice we found our standards were so definite that we always indicated the sensibility in a given case, examined independently, either by the same number or occasionally by numbers differing by one, but never by more. We then systematically recorded the sensibility in a large number of men, some healthy, some suffering from a great variety of surgical and medical conditions, and others from definite hysterical symptoms, the nature of which was always finally confirmed by their cure by means of psychotherapy. We made our examination without indicating to the patient what object we had in view. He was told to open his mouth, and the back of the pharynx and soft palate was then touched with some blunt object, the tongue being depressed when necessary. In the rare cases in which no reflex was produced the man was asked what he had felt during the examination. The accompanying curves show the pharyngeal sensibility in 170 individuals with no hysterical symptoms and 64 with hysterical symptoms. A third curve shows separately the cases of hysterical aphonia and mutism, which are also included in the second. We have analysed these, because it is often asserted that pharyngeal anaesthesia is particularly

Three Graphs to Illustrate Pharyngeal Sensibility in Hysteria.

FIG. 3.—34 cases of hysterical aphonia or mutism.

Percentage of cases is given at the left and degree of sensibility at the foot of each chart.

hysteria is exceedingly probable." The qualification concerning bromides was thought necessary on account of the observation of Huette in 1850 that the pharynx becomes anaesthetic and the pharyngeal and palatal reflexes disappear in patients taking bromide, an observation which has prompted many physicians to give the drug to patients before examining them with the pharyngoscope since the procedure was first suggested in 1867 by Gasselin. It can, however, be of little or no real value, as Krosz found in 1876 that it required an enormous dose, such as between 125 and 150 gr. taken at one time to abolish the pharyngeal reflexes, 100 gr. never being sufficient. My own observations also show that the supposed effect of bromide on the pharynx, which has been copied from book to book, is non-existent, as careful measurement of the pharyngeal excitability in ten cases of epilepsy before receiving bromide and after taking between 45 and 80 gr. a day, often for several weeks, in no single case produced any alteration.

The question is not merely of theoretical interest, as during the last few years I have seen many cases diagnosed as hysterical on account of the presence of pharyngeal anaesthesia. One neurotic young woman barely escaped with her life, because the discovery of pharyngeal anaesthesia led her physician to diagnose an attack of abdominal pain as hysterical in origin, although the delayed operation showed she was suffering from acute appendicitis. The presence of pharyngeal anaesthesia has often been mentioned in

well marked in hysterical aphonia, just as hysterical anaesthesia is said—quite erroneously—to occur in the external ear in hysterical deafness, in the cornea, conjunctiva, and eyelids in hysterical blindness, and so on, assertions which we have found to have not the slightest foundation in fact.

In several cases of hysterical aphonia, as well as of other hysterical symptoms, it was found that the pharyngeal excitability remained unaltered after a cure had been obtained. The single case in which complete pharyngeal anaesthesia was present was that of a stolid individual, convalescent from neurasthenia due to simple exhaustion. He had had no hysterical symptoms and there was no history of hysterical manifestations in the past.

These figures show conclusively that pharyngeal sensibility is no more deficient in individuals suffering from hysterical aphonia or other hysterical symptoms, such as paralysis, contractures, fits, blindness, or deafness, than in individuals who neither are suffering nor have ever suffered in this way, and varies in a similar manner in different people. When care is taken to avoid suggestion, complete pharyngeal anaesthesia is hardly ever found, and the comparatively rare absence of reflexes is met with in normal people just as often as in patients with hysterical symptoms. Curiously enough, in the only example of organic disease in a series of 100 consecutive cases of aphonia in soldiers, laryngoscopic examination was unusually easy owing to the extremely slight degree of pharyngeal sensibility. If pharyngeal anaesthesia had been taken as a sign of any value it would thus often have led to erroneous diagnosis.

These investigations were all made on soldiers, but I carried out a similar investigation on a large number of patients at Guy's Hospital a few years ago and obtained precisely similar results, although about half of the non-hysterical patients and nearly all the hysterical ones were

women. Unfortunately, the exact figures have been lost, but they did not differ in any way from the present series.

We may thus conclude that pharyngeal anæsthesia is not a stigma of hysteria, and that when it is habitually found by a given observer it must be produced in the majority of the cases by involuntary suggestion on his part. As most patients suffering from hysterical symptoms are abnormally suggestible, it is more likely to be found by careless examination in such individuals than in others. As many individuals suffering from organic disease are equally suggestible, pharyngeal anæsthesia may easily be produced in them. Conversely, in the not uncommon cases seen under the peculiar conditions of modern warfare, in which hysterical symptoms developed as a result of an overwhelmingly powerful suggestion in men who were not abnormally suggestible, pharyngeal anæsthesia would not be produced by careless examination, and the hysterical nature of the symptoms might be doubted if any importance were attributed to pharyngeal anæsthesia as a stigma of hysteria.

In order to explain the frequently repeated assertion that laryngoscopic examinations are particularly easy to make in patients with hysterical aphonia, it must be remembered that about 25 per cent. of patients suffering from aphonia or other hysterical symptoms have, like a similar proportion of normal individuals, a comparatively insensitive pharynx (1 or 2 in our scale). The insensibility would not be remarked upon in a normal individual; but its association with hysterical symptoms would at once strike an observer who had been taught to regard pharyngeal anæsthesia as a stigma of hysteria, and the one case confirming this would make more impression on his mind than the three in which the pharynx was more sensitive. Moreover, our observations show how easily pharyngeal anæsthesia is produced by suggestion, and a few words of encouragement by the observer would be enough in many cases to render a previously sensitive pharynx insensitive, although the observer might have no notion that his words would have any such effect. In most individuals the pharyngeal sensibility remains unaltered on repeated examination, but in abnormally suggestible men, whether they are actually suffering from hysterical symptoms or not, we have frequently been able to reduce the sensibility from 3, 4, or 5 to 1 or 2 by direct suggestion.

(c) Rectal Anæsthesia.

The only other mucous membrane which requires brief consideration is that of the rectum, as numerous French writers, ever since Gendrin first referred to the condition in 1846, have regarded anæsthesia of the rectal mucous membrane as a cause of constipation. It is curious that not one of them should have taken the trouble to investigate the sensibility of the rectum in normal individuals. In my Goulstonian lectures on the Sensibility of the Alimentary Canal I described how I had found that the mucous membrane of the rectum is totally insensitive to tactile, thermal, and painful stimuli, so that whatever importance deficient sensibility of the muscular coat of the rectum may have in the production of dyschezia, anæsthesia of the mucous membrane is the normal condition, and neither a result of hysteria nor a cause of constipation.

CUTANEOUS HYPERÆSTHESIA.

If the view be accepted that the physical basis of attention to sensory stimuli is a diminished resistance at the synapses in the sensory tract involved, and that hysterical anæsthesia with the corresponding loss of reflexes is caused by inattention, it is easy to explain the occurrence of hysterical hyperæsthesia. When for any reason an individual's attention is fixed to an abnormal degree on sensations coming from a certain area of skin, the resistance at the synapses in the tract conveying impulses from this area to the brain is diminished to a greater extent than under normal conditions. It may be supposed that whilst ordinary attention results in a considerable degree of approximation of the dendrites of adjacent neurones at each synapsis, the excessive attention in hysterical hyperæsthesia results in still greater approximation

owing to the extreme degree of projection of the dendritic terminations. Whereas the abnormally great resistance at the synapses in hysterical anæsthesia results in diminution or loss of the corresponding reflexes, the abnormally small resistance at the synapses in hysterical hyperæsthesia results in their exaggeration.

I do not propose to discuss the causes of hysterical hyperæsthesia at any length. But I should like to draw attention to the frequency with which cutaneous hyperæsthesia results from unconscious hetero-suggestion on the part of the observer in exactly the same way that hysterical anæsthesia so often arises. This is seen most frequently in connexion with the areas of cutaneous hyperæsthesia which are supposed to occur in association with visceral disease.

In my first enthusiasm for the brilliant investigations on the subject by Head, which I read as a student in 1903, I found that I could confirm his observations in every case which I examined. Being particularly interested in the cutaneous hyperæsthesia associated with digestive disorders, I acquired the habit of mapping out Head's area in every case diagnosed as ulcer and watching its retraction from day to day as improvement occurred until it finally disappeared, when it was assumed that the ulcer had healed. My first doubt on the subject arose when I had the opportunity in 1909 of seeing ten patients operated on by Moynihan for duodenal ulcer. I had examined them with great care the previous day and I had entirely failed to find any cutaneous hyperæsthesia, but the ulcer was none the less demonstrated in nine out of ten of the cases at the operation. From that time I have never been able to find any evidence of cutaneous hyperæsthesia in cases of gastric or duodenal ulcer, although I have repeatedly searched for it. Whereas the majority of my earlier cases had occurred among highly suggestible, chlorotic girls, who had up to that time been regarded by most physicians as particularly subject to gastric ulcer, Moynihan's patients were mostly middle-aged phlegmatic Yorkshiremen. With greater knowledge of the symptoms of ulcer and of the conditions which simulate it, and improved accessory methods of diagnosis with the aid of the X rays and chemical examination of the gastric contents and faeces, it has become recognised that chronic ulcers are comparatively rare among chlorotic girls, the very people who were formerly supposed to be most subject to them and in whom hyperæsthesia would be most easily suggested. In examining for hyperæsthesia it must be remembered that, unless the greatest care is taken to avoid the possibility of suggestion, it is very easy to produce hyperæsthesia in the area in which it is expected. When improvement occurs under treatment both the physician and patient expect the area to become smaller, and so indeed it does, but not as a result of the healing of the ulcer, but of the physician's hetero- and the patient's auto-suggestion. I have now many times suggested an area of hyperæsthesia away, replaced it by anæsthesia, or transferred it to the opposite side, after it had been carefully marked out by one of my clinical clerks. I have no doubt that the areas of hyperæsthesia had been suggested, just as I had suggested similar areas before I learnt how to avoid doing so.

I do not mean that Head's areas are always the product of suggestion on the part of an observer, looking for hyperæsthesia in a certain zone in a patient who is unduly open to suggestions of the kind owing to abnormal suggestibility and to the presence of symptoms, such as pain, which draw his attention to the area as the probable seat of disease. But I believe that they occur so rarely in diseases of the œsophagus, stomach, intestine, liver, and pancreas as to be of no diagnostic value. Only in diseases of the kidney, which lead to distension of the pelvis, does true cutaneous hyperæsthesia appear to be of some frequency; but even in these conditions the areas of skin involved are much less constant than is often supposed.

It is interesting to note that when these areas of cutaneous hyperæsthesia, unconsciously suggested in the way I have described, are unilateral, the abdominal reflex obtained from the suggested area is brisker than that on the other side, confirming the view I have advanced of the physical basis of hysterical hyperæsthesia. The reflex becomes normal once more when the hyperæsthetic area disappears as a result of suggestion.

HYSTERICAL PAIN.

It is a matter of common experience that pain is increased by attention and diminished by inattention. In all probability individual variations in sensibility to pain depend largely upon the varying ease with which the attention can be diverted by an effort of will from the seat of pain. The anatomical basis I have suggested as an explanation of variations in cutaneous sensibility

to tactile stimuli can probably be extended to explain variations in sensibility to pain. In this connexion I have already referred to the hysterical analgesia which is often associated with hysterical anaesthesia. In the converse condition an individual may be unusually sensitive to pain owing to his inherited mental characteristics, or he may become so owing to exhaustion, insomnia, and sepsis, and the demoralisation which prolonged and excessive pain may induce. This acquired sensibility to pain was comparatively common in soldiers. A man may train himself to such an extent to feel pain that the diminished resistance at the synapses in the tract conveying painful impulses to the brain may persist after the primary cause of pain has been removed. The persistent pain is hysterical, being suggested by the original organic pain, and being curable by psychotherapy.

A patient may continue to feel pain after his diseased appendix has been removed as the result of very slight painful impulses produced in the deep tissues and scar, which an average individual would ignore. The following is one of several cases of the kind which I have observed both in soldiers and civilians.

Hysterical pain following appendicectomy cured by psychotherapy.—Pte. G., aged 24, had had over two years' active service in France and Italy when he developed an acute attack of appendicitis on July 6th, 1918. He was operated upon the same night, two tubes being inserted. He was transferred to a hospital in England, and was allowed to get up on August 16th. Since then he had had constant sharp pain in the region of the scar. He was sent to his depot and told that the pain would go in time. He was given clerical work, but could not do it, and was transferred to Seale Hayne Hospital under Captain S. H. Wilkinson on Dec. 21st, 1918. He complained of constant pain in the region of the scar, especially when in bed. In a long therapeutic conversation it was explained to him that the original pain had made a great impression on his mind, because at the time he was physically and mentally tired from constant active service for over two years; in spite of the fact that the cause of the pain had gone, his mind had got so accustomed to feeling the pain that he continued to feel it. The pain disappeared completely, and two days later he was given work on the farm. There had been no return of pain when he was discharged a month later.

The pain felt in the scars of wounds long after they have healed is, I believe, in many instances of the same nature. It has generally been ascribed to nerve fibres becoming involved in scar tissue, but nothing abnormal may be found at operation, or complete excision of the scar may produce no improvement, the pain persisting in the new scar. We saw numerous cases of this kind, which were often associated with hysterical paralysis or contracture, in which severe pain was rapidly cured by psychotherapy.

It is generally assumed that the headache following the explosion of a shell in the immediate neighbourhood, especially if consciousness was lost, is due to concussion. If this is correct, so-called "shell shock headache" is of exactly the same nature as the headache which follows concussion in civil life. It is well known that the most effective treatment of the latter is rest, but that if insufficient rest is taken in the earliest stage the headache is likely to be prolonged for an indefinite period. This has proved to be the case in "shell shock headache," and all who have had such cases under their care must have been struck by the extreme difficulty of relieving the headache by ordinary means. The analgesic drugs, which give at any rate temporary relief for most forms of headache, are either entirely without effect or only produce a slight amelioration of the pain. If a considerable period has elapsed since the onset of the headache, during which the patient has been getting about, a renewed period of rest is generally of comparatively little use. In a number of cases we were struck by the complete relief which immediately followed a lumbar puncture, but unfortunately this was rarely permanent and often only lasted for a day or two. We were at the time unable to explain this, as the fluid was never under increased pressure, so that it did not seem possible that the improvement was due to the reduction of an abnormally high intracranial pressure.

The following case seems to give a clue to the explanation of the persistence of the headache in some of these cases:—

"Shell shock headache" cured by hypnosis.—Cpl. H. served from August, 1914, and remained well until he was blown up in November, 1917. He was away from his unit for a month on account of a stammer and tremor. He then returned to duty, but was wounded

in April, 1918. He was now sent to hospital, and after six months' treatment for neurasthenia was admitted to Seale Hayne Hospital under Captain C. H. Ripman in October, 1918. He was shaky and complained of a heavy pain in the head during the day, which had been present ever since he was blown up. During the whole night he sat up in bed holding his head and crying with pain. In spite of the severity of the pain he was not inclined to make much of it during the day. He was treated with drugs, none of which had any effect. Hypnosis was consequently tried. The headaches improved at once. After the first treatment he slept through the night and he had no headache the next day. After three treatments he felt perfectly well and became one of the most lively men in the ward, having previously spent all day curled up on his bed and all night crying with pain. He was discharged a month later and wrote in February, 1919, to say that there had been no return of his headache.

In this case, in spite of the extreme severity of the headache, complete relief was produced by suggestion without any accessory factor coming into play. It is inconceivable that suggestion, by which is meant the communication of a proposition without giving adequate and logical grounds for its acceptance, could have produced such a result in a headache of organic origin. Consideration of this case points to the possibility that the relief produced in our earlier cases by lumbar puncture was due to suggestion, and the absence of any relief with ordinary analgesic drugs could be explained on the assumption that the headache was of entirely psychical origin. It is probable, therefore, that the explanation of the long-continued and intractable headache following the concussion caused by a high-explosive shell is due to the perpetuation by auto-suggestion of a headache, which is at first organic in origin and a genuine result of concussion. Being produced by suggestion and cured by psychotherapy, it can be correctly called hysterical.

The chronic headache which follows concussion in civil life is probably often of similarly hysterical origin.

Hysterical headache following concussion.—A lady, 49 years old, an artist by profession, fell on her head in February, 1917, as the result of a collision with a motor lorry whilst she was driving a dogcart. She was badly shaken, but was not rendered unconscious. Severe headache developed immediately afterwards. It persisted all day, and at night prevented her sleeping. She did not improve in spite of wearing spectacles for astigmatism and giving up painting and reading since her accident. In October, 1918, she was told that the pain was rheumatic, and was ordered a strict diet and massage for her head. After this she became terrified of cold and damp, and kept indoors almost all the time, but whenever the weather was bad the headache was much aggravated, although this had not hitherto been the case.

I saw her for the first time on March 1st, 1919, when I explained to her that the headache was simply a perpetuation of that due to the original concussion. I told her that as the effects of the latter had long ago passed away she would no longer have any headache if she ceased to expect it. I explained to her that it was clearly not due to her astigmatism, as her glasses had not helped her, and she was no better when she did not read or paint, and that the failure of her dietetic precautions and staying indoors had proved that it was not rheumatic. On my advice she gave up her glasses and began to read and paint, and she went out whatever the weather was like. I saw her a week later and she had only had one slight headache, which had come on during a rainstorm, this having been apparently again suggested by the weather. Further explanation resulted in complete disappearance of the headache in spite of taking no further precautions to prevent it. She was given no drugs, and the various medicines she had taken before both during the day and at night for her insomnia were discontinued. From the first conversation she slept perfectly well. She wrote on April 16th to say she was still free from headache.

Hysterical pain is a very real thing and cannot be distinguished from pain caused by organic disease by its character or by the absence of associated sympathetic phenomena. It may, for example, give rise to tachycardia, dilatation of the pupils, pallor, and sweating, if the original organic pain did so, because the afferent tract of the reflex paths involved offers so little resistance to impulses excited by peripheral stimuli that the latter still produce marked effects, even if they are so slight that if the patient would cease to expect pain and so allow the normal resistance to return, they would either produce no effect at all or only an insignificant amount of pain and little or no sympathetic reflexes.

SYMPTOMLESS INFLUENZAL (STREPTOCOCCAL) MASTOIDITIS.

BY FRANCIS F. MUECKE, C.B.E., M.B., F.R.C.S.,

ASSISTANT SURGEON TO EAR, NOSE, AND THROAT DEPARTMENT,
LONDON HOSPITAL; ASSISTANT SURGEON, THROAT HOSPITAL,
GOLDEN-SQUARE; AURAL SURGEON, MAIDA VALE HOSPITAL;

AND

C. GRANTHAM-HILL, M.B., B.CH., M.R.C.S., L.R.C.P.,

SENIOR HOUSE SURGEON TO AURAL DEPARTMENT,
LONDON HOSPITAL.

THE possibility of the occurrence of a very acute mastoiditis, with few, if any, of the usual symptoms, was first brought to our notice by several cases in which the original condition was deduced by tracing back the undoubted steps of development of the complication which was the first recognisable feature. The sequelæ which we were called upon to treat in our three original cases were lateral sinus thrombosis, peri-sinus abscess, and extra-dural abscess, all three unexpectedly appearing without any of the usual signs or symptoms of mastoiditis. Fortunately, we were enabled to supplement this experience by the study of a minor epidemic of influenza, with middle-ear complications, occurring amongst the staff of a large institution in which we were able closely to watch the progress of the disease.

Noteworthy Features.

The first cases followed, almost exactly, the course of our original three, and displayed the following noteworthy features:—

1. A very acute onset of earache occurring in the second or third day of a mild influenzal attack comprising pyrexia, malaise, coryza, and pains in the trunk and limbs.
2. The upper part of the drum was generally alone affected, displaying redness and bulging from the beginning.
3. Perforation occurred early, followed by unusual hæmorrhage lasting for several days, accompanied by complete relief of all pain.
4. The posterior meatal wall became red and swollen shortly after the appearance of the discharge.
5. The discharge, at first slight, became in the second or third day profuse, coinciding probably with mastoid suppuration.
6. After perforation, other than discharge, there were no symptoms. That is to say, no pain, pyrexia, increase of pulse-rate, mastoid tenderness, or malaise.
7. On opening the mastoid, which was invariably of the pneumatic type, the chisel exposed softened, red, marrow-like bone, which showed early necrosis and absorption with the formation of large cavities full of pus. The extension was generally downwards and backwards.
8. The incomplete operation was performed in all cases, although in several the so-called "bridge" had already suffered necrosis.
9. The subsequent progress was unusually rapid and uneventful, and in no case has the hearing been appreciably affected.
10. In all cases streptococci of the hæmolytic influenzal type were found in large numbers.

Record of Cases.

To save repetition in the description of the cases we have omitted details of symptoms, onset, &c., unless they in any way diverge from the typical form as already set forth.

CLASS A.—*Comprising five cases. First seen late in the course of the disease. Complications found at operation.*

(1) Boy, aged 13. Seen three weeks after typical onset. Temperature 105° F. at night, subnormal in morning. Drum and meatal appearances as described. Slight discharge. No other symptoms. *Operation.*—Lateral sinus thrombosis. Large peri-sinus abscess. Internal jugular vein tied. Recovery after three weeks of septicæmia with normal hearing. Streptococci isolated from pus, thrombus, and blood culture.

(2) Man, aged 54. Seen seven weeks after typical onset. Discharge profuse. Drum and meatal appearances as described. Patient doing his usual work on the Stock Exchange. *Operation.*—(1) Incision of drum, no diminution of discharge. (2) Next day antrum opened. Large peri-sinus abscess extending from bend

to bulb. Sinus not thrombosed. So-called "bridge" much eroded. Middle ear left intact. Uneventful recovery with normal hearing.

(3) Man, aged 62. Seen three weeks after typical onset. Discharge profuse. Signs as described. Operation refused at first as patient felt "perfectly well." *Operation.*—(1) Incision of drum. (2) Incomplete operation (four weeks from onset). Large subdural abscess. Definite area of necrosis close to promontory. Facial palsy third day after operation, disappeared one week later. Progress uneventful. Hearing normal.

(4) Girl, aged 9. Seen fourteenth day after ordinary onset. Obviously ill, with vomiting and rigors. Signs as described. Discharge profuse. No symptoms until onset of septicæmia. *Operation.*—Large peri-sinus abscess. No apparent thrombosis. Internal jugular tied two days later on recurrence of rigors. Death on fifth day after admission to hospital. *Post mortem.*—General bacterial pyæmia with no large infarcts.

(5) Girl, aged 14. Seen 14 days after typical onset. Discharge very profuse from both ears. Much deafness and slight earache. Drum and meatal appearances only slightly suggestive. Watched for four days. *Operation.*—As discharge was increasing. Left side: Large peri-sinus abscess. Right side: Mastoiditis; pus in antrum and cells. Discharged in five weeks. Hearing excellent.

CLASS B.—*Six cases operated on before onset of complications.*

(1) Sister. Seen ten days after ordinary onset. More pain than usual, as the perforation was constantly healing, leaving pus under tension. Incision of drum on two occasions. *Operation.*—Pus found throughout a very pneumatic mastoid. Aditus much eroded. Progress uneventful. Hearing good.

(2) Nurse. Seen seventh day. Typical onset, symptoms, and signs. *Operation.*—Free infection of pneumatic mastoid. Progress uneventful. Hearing normal.

(3) Sister. Seen 14 days after typical onset. Course complicated by empyema of maxillary antrum on the same side. *Operation.*—Extensive mastoid infection. Progress slow but uneventful. Normal hearing.

(4) Nurse. Seen four days after onset. Large perforation of lower quadrant of drum. Slight redness of posterior meatal wall. Watched for 14 days with apparent improvement. Sudden increase of discharge, with simultaneous bulging of posterior meatal wall. *Operation.*—Free infection of very pneumatic mastoid. Aditus carious. Progress satisfactory. Hearing only moderate.

(5) Nurse. Seen second day. No discharge. Slight bulging of upper quadrant of drum and meatal wall. Incision resulted in slight discharge. Increase of meatal bulging and quantity of discharge. *Operation.*—Pneumatic mastoid full of polypoid granulations. Erosion of aditus. Progress satisfactory.

(6) Girl, aged 11. Seen fourteenth day. Typical case. *Operation.*—Pus throughout mastoid. Antrum and aditus carious. Progress uneventful. Hearing normal.

CLASS C.—*Cases seen from first onset (four cases).*

(1) Boy, aged 11. Seen in first 24 hours. Appearances typical. *Operation.*—Third day. Large carious antrum communicating with lateral sinus. Progress uneventful.

(2) Nurse. Seen in first 24 hours. Typical. *Operation.*—Third day. Large antrum with purulent contents. Swollen mucosa, but no pus in mastoid cells.

(3) Nurse. Seen second day. The perforation in this case occurred on the second day, and was not, as usual, in the drum, but at the apex of the swelling of the posterior meatal wall. A probe could be passed through this perforation into the antrum. This occurrence illustrates the mechanism of the production of the meatal swelling. *Operation.*—Third day. Antrum freely infected. Aditus eroded.

(4) Boy, aged 10. Seen 12 hours after onset of earache. Semi-comatose. All signs of basal meningitis. Drum bulging in upper quadrant, but no perforation. Redness of posterior meatal wall. *Operation.*—Large subdural abscess, with extensive gangrene of dura. Condition of patient forbade further operation. Death 20 hours later. *Post mortem.*—Whole cisterna basalis full of thick yellow pus, connected with antrum by track leading through hole in roof of antrum.

Importance of Early Recognition.

The fact we particularly wish to emphasise is that after perforation the patient was apparently proceeding satisfactorily, being free from all symptoms and often able to resume his ordinary pursuits until one or other of the dangerous sequelæ arose. Hence the importance of the early recognition of the only sign we have found to be constantly present—namely, the redness and swelling of the upper drum and postero-superior meatal wall, together with the continuance, and especially the increase, of the discharge in a case of otitis media following influenza.

We have classified our cases into three categories: (a) Cases not recognised until the occurrence of dangerous sequelæ; (b) cases seen shortly after the appearance of the discharge; (c) cases followed from the onset.

This arrangement more or less represents our progressive knowledge of the disease, and we have little hesitation in believing that if the cases in Class C had not been treated when they were they would have run the grave risk of following the same course as those in Class A.

In Class B it will be noticed that we attempted on several occasions to forestall the onset of mastoiditis by incision of the drum. Except in one case, which is not recorded, our efforts were unsuccessful.

THE CLASSIFICATION OF PULMONARY TUBERCULOSIS.

BY L. S. BURRELL, M.A., M.D.,

ASSISTANT PHYSICIAN TO THE BROMPTON HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST.

IN selecting a suitable classification for pulmonary tuberculosis one must bear in mind the objects of the classification.

Methods of Classification.

From the point of view of one arranging museum specimens a basis of morbid anatomy is clearly indicated, and one would found the classification on such changes as excavation, caseation, or the amount of lung involved. This is an unsuitable method when dealing with the living subject. Not only is it difficult to determine clinically how much lung is involved and exactly in what condition the lung is, but the extent of the disease, and more especially the anatomical stage, are often poor indications of the condition of the patient. For instance, excavation, a late stage in the morbid anatomy, is often found in most satisfactory cases.

A classification based on the systemic disturbance is more useful for the clinician. This may be combined with the anatomical changes which accompany the disease, as in the classification of Sir Robert Philip.

The Turban classification which is based on morbid anatomy may be modified (as suggested by Meissen) by the addition of the letters F or f to denote severe or slight pyrexia.

Dr. A. C. Inman's classification is based on pyrexia, and he divides the cases into: (1) resting febrile; (2) resting afebrile, ambulant febrile; (3) ambulant afebrile. This classification has the great advantage of being simple, definite, and not dependent on the opinion of the examining physician. It does not, however, differentiate between the fever found in early cases and that found in late, nor can one easily place the large number of chronic cases who have occasional bouts of fever but live a long time and get into an advanced stage of the disease with little or no pyrexia.

Dr. R. C. Wingfield has modified the Inman classification by adding letters to indicate the patient's fitness for work. This certainly gives a better picture of the patient's condition.

Stages in Life-history of a Consumptive.

A classification might well be based on the vital capacity constants as worked out by Professor G. Dreyer, and by this means one could define the exact condition of the patient. One could say he was so much per cent. below normal. This method seems to me to be of the greatest value, but to employ it as a standard method of classification at present is open to several objections. It does, however, enable one to follow the life-history of the patient.

If we follow the life-history of a consumptive from the time when the disease is first recognised until the end we find three distinct stages.

In the first the patient is receiving institutional treatment with a view to improving his condition or curing the disease. Sooner or later the patient reaches the second stage, when, having received as much benefit as possible from institutional treatment, he returns home and probably to work. He usually requires no special treatment, though he may be kept under observation at some out-patient department, and perhaps have some symptomatic treatment. He may require some special treatment, such as tuberculin or artificial pneumothorax, but this is now carried on whilst he is outside the institution. Then comes the third stage, when he begins to lose ground, and although the progress of the disease is often not a gradual decline, but consists of periods of ill-health alternating with periods of slight improvement, it is found that every six months the patient is worse.

Suggested Classification.

The classification I suggest is based on this life history. The first stage, A, is subdivided into (1) the hospital stage, and (2) the sanatorium stage.

The hospital stage includes patients in whom pulmonary tuberculosis has just been diagnosed and who require observation in hospital or in bed at home to enable the physician to determine the proper treatment and to see the patient's response to treatment. It may be regarded as the stage of initial rest. If the patient improves sufficiently to stand a sanatorium life he passes into the sanatorium stage. Here the patient remains until he reaches the stage of maximum improvement. He then passes into the second stage, B. This includes all patients who, having received the maximum benefit from institutional treatment, are holding their own, but in whom the disease is not arrested.

Stage 3 is the stage of decline, and includes patients who are losing ground in spite of treatment.

These stages are subdivided as follows:—

A. *Stage of institutional treatment.*—1. *Hospital stage.* a. In bed, or up less than two hours a day. β. Up from two to six hours a day.

2. *Sanatorium stage.*—a. Capable of less than half a day's work. β. Capable of half a day's work. γ. Capable of a full day's work.

B. *Stage of maximum improvement.*—1. Capable of a full day's work. 2. Capable of part-time work. 3. Unable to work.

C. *Period of decline.*—1. Able to do some work. 2. Unable to work. 3. Bedridden.

Discussion of Method.

When, therefore, the physician first diagnoses pulmonary tuberculosis he classifies the patient A1a. Whether the treatment is actually given in hospital or in the patient's private house does not matter. Possibly the patient is found to have acute tuberculosis and rapidly gets worse; in this case he would, of course, come into Class C3. On the other hand, it may be found that he can pass quickly through Classes A1a and A1β, and is suitable for sanatorium treatment. The hospital stage is therefore that period of the disease during which the physician can observe the patient's response to treatment, and can decide whether he is fit for sanatorium treatment or not, and if fit, for which sanatorium he is best suited. If he is not fit he goes into Class B or Class C.

It may be thought that Class A could better be subdivided without the terms hospital and sanatorium. The names may be misleading, for many a sanatorium has a hospital side, and some hospitals give what is practically sanatorium treatment. I think, however, that the subdivisions are important. The true functions of hospital and sanatorium are entirely separate, and this subdivision serves a useful purpose if it emphasises the importance of the initial stage of rest and observation, a stage so often forgotten. Many a patient is hurried into a sanatorium when the correct treatment is rest, and often the wrong sanatorium is selected because the period of observation has been ignored.

Some patients in B Class may sooner or later require further institutional treatment with a view to patching them up again. Such cases should, I think, be classified B3, and the words hospital or sanatorium added to distinguish them from the ordinary B Class, where no institutional treatment is required, and from those who are having institutional treatment in the early or A stage. This would not be such a large group as one might suppose, for it is usually found that such breakdowns are the beginning of the stage of decline. Thus, one would write B3 Sanatorium, or B3 S. After a short time one could decide whether the case should belong to the C Class or could be restored to the ordinary B Class again.

Advantages of Method.

In this classification there is no place for doubtful cases. Such cases are best referred to as cases for diagnosis. In a classification of any disease obviously no case should be included until it has been proved to be a case of that disease.

Similarly, if the disease is cured it cannot be included, and such cases are best referred to as arrested cases. If the disease breaks out again then the patient can once more be classified.

I have entirely ignored physical signs, but there is a chest diagram in all report sheets on patients, and a glance at these will give a more accurate idea of the amount of disease than any classification based on anatomy.

The classification I have suggested is simple and avoids matters about which there can be much difference of opinion. It enables one to classify an early case with no physical signs; for instance, after hæmoptysis with T.B. present. One can also distinguish between the good case with severe signs and the bad case with few, and between the A1 α and C3 cases, both of which are bad cases. Moreover, one can follow the course of the disease. For example, if one received monthly reports of a patient and found after six months the following classifications, A1 α , A2 α , A2 γ , A2 γ , B1, B1, one could at once see that the patient has soon gone to a sanatorium where he did well, and that after some three months still had active disease, but was keeping at full work.

SULFARSENOL IN THE TREATMENT OF SYPHILIS,

WITH SPECIAL REFERENCE TO ITS ADMINISTRATION BY HYPODERMIC INJECTIONS.

BY F. CARMINOW DOBLE, M.R.C.S., L.R.C.P.LOND.,
TEMPORARY CAPTAIN, R.A.M.C.; OFFICER IN CHARGE, "B"
SYPHILIS BLOCK, MILITARY HOSPITAL, ROCHESTER ROW.

SULFARSENOL is a French preparation, manufactured by M. R. Pluchon at his bio-chemical laboratory in the Rue Michel Ange, Paris. It has the formula— $C_{12}H_{11}As_2N_2CH_2OSO_2Na$, and is a pale yellow, finely-divided powder, smelling rather like galy. It dissolves very easily in water, making a very stable neutral solution.

Notes from Latest French and Belgian Literature.

(a) MM. Levy-Bing, Lehnhoff-Wyld, and Gerbay have given a large number of injections by the intravenous, intramuscular, and subcutaneous routes. By the last method they have given doses of 0.12 g. and 0.18 g. in 1 c.cm. distilled water.

(b) MM. Yernaux and R. Bernard, of Brussels, have studied the methods of subcutaneous injections.

They make a solution of the strength of 0.06 g. per c.cm. of distilled water, and have injected at one time as much as 1.20 g. in 20 c.cm. of distilled water. The largest amount given by them in one month without any sign of intolerance has been 12 g. For intramuscular injections they at first dissolved the drug in a glucose mixture, but distilled water was found to be better, as the sulfarsenol was easier to dissolve, the solution was less sticky, and the results were equally good.

Their method of injection was as follows. Starting with 0.12 g. to 0.18 g. to test the susceptibility of the patient, the dose was rapidly increased to 0.3 g., 0.48 g., and 0.6 g., giving not more than 0.3 g. into one buttock. As the patients complained of having an injection into both buttocks on the same day, the full dose was injected into one. Later on they arrived at the fair-sized dose of 0.6 g. in 1 c.cm. of distilled water in one buttock every 6-7 days. Some of the injections seem to have been painful; sometimes pain was complained of at the site of the injections, at other times down the thigh or in the foot. Numbness was caused in a few cases. In from 6 to 10 hours these sensations usually disappeared suddenly, and did not interfere with walking or stop the patient from working. Rarely was he unable to carry out his occupation on the day following the injection. The results of using local anæsthetics, such as novocaine or stovaine, were not good.

The injection of these very concentrated solutions did not cause many reactions, either local or general. All the primary sores on the penis healed 24 or 25 days after 2 g.; chancres of the lip in from 25 to 30 days.

In summing up, they state that sulfarsenol is equal to, if not better than, N.A.B. Sores heal up quickly and the induration and enlargement of the glands rapidly disappear. It is equally useful in secondary syphilis. They state that in tertiary syphilis it acts as quickly as N.A.B. They had no Herxheimer reaction in any of their cases. It was unusual to find the *Spironema pallidum* in the sore on the day

after the injection, and it was never found on the third day. After a total of 4 g. at most these workers have obtained a negative Wassermann. One of their patients had two slight nitritoid crises, showing that they are not caused by intravenous injections, but are due to arsenic, and can be produced without a Herxheimer reaction. They also got good results in acute and chronic eczema, a stubborn psoriasis, and a Vincent's angina.

M. Galonnier has shown that the elimination of arsenic was nearly the same when sulfarsenol was administered intramuscularly as intravenously.

The Method Employed: Efficacy of Treatment.

After reading the latest French and Belgian literature on this drug, and finding that injections dissolved in 10 c.cm. of distilled water were comparatively painless, I decided to try to decrease the amount of fluid, and were in a short time giving 0.42 g., 0.48 g., and 0.6 g. dissolved in 8 to 10 minims of distilled water practically painlessly.

The following was the technique employed. The ampoule is filed through evenly half-way up the neck. From 8 to 10 minims of distilled water is injected into the ampoule with a hypodermic syringe. A thumb is then placed over the opening and the ampoule is well shaken until the drug is completely dissolved; this only takes a few seconds. The fluid is then sucked up into the syringe and injected through a hypodermic needle into the loose skin of the forearm and the site gently massaged.

The spironema is present in the sore on the day following the injection, sometimes on the second day, but never on the third day.

In all cases the juice from the sore or rash has been examined daily under the dark ground, using an Edison and Swan "Pointolite," until the sore has healed or the rash has faded.

The results are about the same as we obtained in primary and secondary syphilis with silver-soda salvarsan. In tertiary cases, especially if ulcerated, the latter drug appears to be the best. Up to the present all sores have been completely healed after the third injection, usually after the first or second.

A few cases, contrary to the experience of the French with this drug, have shown a Herxheimer reaction, but only a very slight and transitory one. In one case, with a very faint early roseolar eruption on the day following the injection of 0.48 g. sulfarsenol hypodermically, the rash was much more marked and looked as if it had been painted on. On the next day the rash was completely gone.

In one case of a man with a relapse after six injections of kharsivan intravenously and five intramuscular injections of mercury in 1917, with large condylomata and sores on his penis and scrotum, the condylomata had gone and the sores completely healed six days after the first injection of 0.42 g. sulfarsenol hypodermically.

In all our cases so far the Wassermann has been negative after the fifth injection, with a total of from 2.2 g. to 2.4 g. of sulfarsenol.

Mercury was given in all cases, although probably not necessary in cases with a negative Wassermann, which remain negative from five to ten days after the first injection. It will take some time to prove whether or no cases will relapse more readily after treatment with this drug than with "606" or "914," as happened in the case of galy.

Summary.

Sulfarsenol appears to be equal to any other form of salvarsan or neosalvarsan except as regards speed of disappearance of the *Spironema pallidum*, at any rate in primary and secondary cases. The hypodermic method of administration is foolproof and practically painless. It seems an ideal method for infants and those with difficult veins. Up to now I have had no side-effects, not even a slight rise in temperature; the usual contraindications do not appear to be applicable in anything like the same degree as "606" or "914."

Intramuscularly it is less painful than "914," and can be given dissolved in distilled water. Intravenously the slightness of the Herxheimer renders less danger in cases with central nervous symptoms.

I have also used this drug intravenously in acute gonorrhœal epididymitis. One large or medium-sized dose appears to cause more pain shortly after the injection, but in two days the pain has completely gone. With two small injections at two days interval the results were wonderful. I tried 0.12 g., and 48 hours afterwards 0.18 g. The day after the second injection all pain had gone, and the testicle could be freely handled and even squeezed without any complaint from the patient.

Notes of Seven Cases Treated with Sulfarsenol.

IM. = intramuscularly; SC. = subcutaneously; HD. = hypodermically.

CASE 1.—Indurated papulo-erosive sore on left side of prepuce, inguinal glands enlarged on both sides. Wassermann ++ *S. pall.* present on day of injection, none found next day.

13/3/20: Sulfarsenol 0.54 g. IM. Inj. hyd. gr. 1 IM.
19/3/20: Sulfarsenol 0.6 g. IM. Inj. hyd. gr. 1 IM.
26/3/20: Sulfarsenol 0.54 g. IM. Sore healed. Inj. hyd. gr. 1 IM.
9/4/20: Sulfarsenol 0.54 g. IM. Inj. hyd. gr. 1 IM.
16/4/20: Sulfarsenol 0.54 g. subcutaneously in 8 minims distilled water.

18/4/20: WR. —. Total 2.76 g. sulfarsenol.
23/4/20: Rest.
5/5/20: Sulfarsenol 0.42 g. hypodermically. Inj. hyd. gr. 1 IM.
12/5/20: Sulfarsenol 0.48 g. HD. Inj. Hg. gr. 1 IM.

CASE 2.—Chancere on left side of glans penis with an indurated sore in coronal sulcus. Much inguinal adenitis. WR. + + *S. pall.* present on day of injection, absent next day.

5/3/20: Sulfarsenol 0.48 g. IM. Inj. hyd. gr. 1 IM.
12/3/20: Sulfarsenol 0.54 g. IM. Inj. hyd. gr. 1 IM.
19/3/20: Sulfarsenol 0.6 g. IM. Sore healed. Inj. hyd. gr. 1 IM.
26/3/20: Inj. hyd. gr. 1 IM.
13/4/20: WR. —. Total 2.04 g. sulfarsenol.
14/4/20: Sulfarsenol 0.42 g. IM. Inj. hyd. gr. 1 IM.
28/4/20: Sulfarsenol 0.48 g. hypodermically.

CASE 3.—History of primary syphilis June, 1917. Had six injections of kharisivan and 5 of mercury. Admitted with secondary sores on skin of penis and scrotum. Large condylomata round anus. Inguinal and general adenitis. No sign of primary sore. WR. ++. C.S.F. ++. Globulin nil. *S. pall.* present in sores and condylomata for two days after first injection, but not present on the third day. Five days after the first injection the condylomata had healed. Two days later the sores had quite healed and the glands in groin very much smaller.

12/5/20: Sulfarsenol 0.49 g. HD. Inj. hyd. gr. 1 IM.
19/5/20: Sulfarsenol 0.42 g. HD. Inj. hyd. gr. 1 IM.
26/5/20: Sulfarsenol 0.6 g. HD. Inj. hyd. gr. 1 IM.
2/6/20: Sulfarsenol 0.6 g. HD.
6/6/20: Inj. hyd. gr. 1 IM. WR. ++.

CASE 4.—Sore noticed three months before admission. Several primary sores on prepuce and skin of penis. Early erythematous rash chiefly on chest, slightly on arms and back. Throat injected and mucous patches on tonsils. WR. ++. *S. Pall.* present in large numbers on day of injection, also found on first and second day after, not on third day. Slight Herxheimer reaction in rash and round mucous patches on the day after the first injection, but gone on second day.

30/4/20: Sulfarsenol 0.42 g. HD. Inj. hyd. gr. 1 IM.
7/5/20: Sulfarsenol 0.42 g. HD. Inj. hyd. gr. 1 IM.
7/5/20: Sores healed, rash gone. C.S.F. — — —. No globulin. No cells.

14/5/20: Sulfarsenol 0.6 g. HD. Inj. hyd. gr. 1 IM.
21/5/20: Inj. hyd. gr. 1 IM.
4/6/20: Sulfarsenol 0.6 g. HD.
8/6/20: WR. —. Total sulfarsenol 2.04 g.

CASE 5.—Chancere in meatus, induration running down right side of fossa navicularis. Glands in groin enlarged. WR. ++. *S. Pall.* present, none seen after the first injection.

22/3/20: Sulfarsenol 0.42 g. IM. Inj. hyd. gr. 1 IM.
29/3/20: Sulfarsenol 0.42 g. IM. Sore healed, only slight induration. Inj. hyd. gr. 1 IM.
12/4/20: Inj. hyd. gr. 1 IM.
19/4/20: Sulfarsenol 0.48 g. SC. in 10 minims of distilled water. WR. ++. Inj. hyd. gr. 1 IM.
26/4/20: Sulfarsenol 0.54 g. HD. Inj. hyd. gr. 1 IM.

3/5/20: Rest.
6/5/20: WR. + (weak negative). Total 2.34 g. sulfarsenol.

10/5/20: Sulfarsenol 0.48 g. HD. Inj. hyd. gr. 1 IM.
17/5/20: Sulfarsenol 0.42 g. HD. Inj. hyd. gr. 1 IM.

CASE 6.—Sore ulcerating through prepuce exposing glans penis, and erosive ulcer on skin of penis half way up shaft. History of syphilis 1918. WR. ++. *S. Pall.* detected in sores on day of injection, but not subsequently.

16/2/20: Neosalvarsan 0.45 g. IV. Inj. hyd. gr. 1 IM.
23/2/20: Sulfarsenol 0.24 g. SC. in 10 c.cm. distilled water. No pain. Inj. hyd. gr. 1 IM.

1/3/20: Sulfarsenol 0.48 g. IM. Inj. hyd. gr. 1 IM.
8/3/20: Inj. hyd. gr. 1 IM.
15/3/20: Sulfarsenol 0.42 g. IM. Inj. hyd. gr. 1 IM.
22/3/20: Sulfarsenol 0.48 g. IM. Inj. hyd. gr. 1 IM.
29/3/20: Rest.

7/4/20: WR. — Neosalvarsan 0.45 g. Total sulfarsenol 1.62 g.
7/4/20: Sulfarsenol 0.42 g. IM. Inj. hyd. gr. 1 IM. Patient transferred to another hospital.

CASE 7.—Admitted with an erythematous rash on chest, shoulders, arms, and abdomen. Well-marked general and inguinal adenitis. Healed sore on prepuce. Mucous patches on tonsils. *S. pall.* found in rash before first injection, not after. The patient was transferred to Rochester Row six days after WR. had been returned positive.

3/5/20: WR. ++.
10/5/20: Sulfarsenol 0.42 g. HD (no Herxheimer in rash or throat). Inj. hyd. gr. 1 IM.

11/5/20: C.S.F. — — —. No globulin, no cells.
17/5/20: Sulfarsenol 0.6 g. HD. Inj. hyd. gr. 1 IM.
24/5/20: Sulfarsenol 0.6 g. HD. Rash gone, throat normal. Inj. hyd. gr. 1 IM.

31/5/20: Inj. hyd. gr. 1 IM.
7/6/20: Sulfarsenol 0.42 g. HD. Inj. hyd. gr. 1 IM.
10/6/20: WR. —. Total 2.04 g. sulfarsenol.

The above experiments have been carried out under the direction of Major Charles F. White, R.A.M.C., Officer Commanding the Military Hospital, Rochester Row, who has kindly given his permission for the

publication of these results. I hope shortly to be able to give a report on a larger number of cases, but thought that in the meantime others might wish to try the above very simple technique of the hypodermic administrations of sulfarsenol in concentrated solution. The sulfarsenol was supplied by Messrs. Wilcox, Jozeau, and Co., of Haymarket, London.

PLEURAL OBLITERATION: A COMPLICATION OF ARTIFICIAL PNEUMOTHORAX.

By W. C. RIVERS, M.R.C.S., D.P.H.

TUBERCULOSIS OFFICER, BARNSLEY DISTRICT, WEST RIDING, YORKS.

IN an address to the Yorkshire Tuberculosis Society recently upon lung collapse therapy, illustrated by radiograph, consideration was given to that unfortunate termination of artificial pneumothorax in which, after an effusion into it, the pleural cavity contracts to obliteration. References to this complication are few. In general, the teaching used to be that pleural effusion could aid in lung compression; but one sees signs now of growth of a more unfavourable opinion, and there are the following definite warnings. Tecon and Sillig¹ say that one result of effusion can be its undergoing rapid fibrous transformation, whereby the two pleural layers are united and continuance of artificial pneumothorax made impossible. Murard,² writing in 1914 on five years' experience and 98 cases, says that effusion can be absorbed, but often there persist new-formed adhesions which end by obliterating the pleural cavity. Riviere³ gives a good description, except possibly for considering it only an occasional outcome of pleurisy. He mentions gradual obliteration of the pneumothorax cavity by the contraction of new fibrous tissue in the organised pleural layers, which can be kept apart by no gas pressure, with the common result of a drawing out and partial re-expansion of the collapsed lung, leading to fresh lighting up of the disease. I give an illustrative case.

E. T., barber, aged 17. Turban-Gerhardt Stadium III. left lung Weight, 8 st. 2 lb.; pulse, 105; respirations, 22; sputum, 2 oz. to 4 oz. daily; temperature touching 102° almost daily for months past. Left pneumothorax induced June, 1915. A mean pleural pressure (calculated by means of Kjer-Petersen's screw) of a little over atmospheric, plus $\frac{1}{2}$ cm. H₂O, at most + 3, was maintained. On the succeeding three-weekly chart the temperature never reached 101°, and the sputum had dropped to 3 ii.; in another month it was normal, and the sputum 5 ss. or nil. In August the temperature rose from normal level to 101°, falling after three days. Small left pleural effusion, on needling serous. At the succeeding refill 390 c.cm. of N changed a mean pressure of - 11 (beginning of operation) to one of + 3½ (end of operation), whereas formerly it took 520 c.cm. or so to make - 9 into + 3. This evident diminution of the pleural space only disappeared temporarily thereafter, when higher mean pressures were resorted to, plus 7 or plus 10. In September the patient began to get up—weight then 9 st. 7 lb.—and take exercise. Condition excellent in all respects until Oct. 16th, when slight vomiting, rise of temperature, and loss of weight betokened another small effusion. With five days in bed apyrexia was regained. On Oct. 23rd exploratory puncture showed plus pressures, although no refill had been given for a fortnight, when the mean pressure had been left at - 2½. The heart was behind the sternum instead of, as formerly, to the right of it. Clearly the whole left pleural cavity was contracting, the pressure readings at subsequent refills confirming this. In November and in December 5 oz. of serous fluid were withdrawn and replaced with N; similarly the next two months. By February, 1916, the apex beat was in its normal position, and a week later moist sounds were audible again over the left upper lobe. Only then did the temperature rise, touching 101° daily and never thereafter falling. Meanwhile higher pressures had been used to antagonise the contraction and a "pocket" discovered in the axilla, but all dilating efforts failed; unfavourable symptoms duly reappeared. After some time a surgeon was obtained who was good enough to interest himself in Sauerbruch's extra-pleural thoracoplasty. Operation July, 1916. The patient's death on the table was in all probability due to use of a general anæsthetic. A somewhat similar case in different hands, also skillfully operated on, and also chloroformed, died on the second day after.

A foreign writer has said that post-pneumothorax effusions are commoner on the left side. However

that may be, I think this is probably true of the complication under notice, because all my cases have been left-sided. Moreover, the left pleural cavity is the smaller, and would have its tendency to contraction aided by the tendency of the dislocated heart to swing back to a normal position.

Pathology of the Condition.

The pathology of this condition has been studied by Jacobaeus.⁴ In his interesting paper on thoracoscopy he gives the histo-pathology of a pleural adhesion in cross section, describing, in the case of cord-like adhesions at any rate, a strengthening of the adhesion, after an effusion has occurred, from development of fibrous tissue (up to a thickness of 1 cm.) upon its surface ("weiteren Auflagerungen von Bindegewebe"). Holmboe,⁵ too, from radiographic investigation, finds that the post-pneumothorax pleural effusion often first appears in the costo-diaphragmatic angle. This is probable enough, for radiologists designate the "costophrenic sulcus" as a common site of small effusions and adhesions. Certainly many workers have considered that an effusion often precedes the recognised physical signs. I have occasionally found the first certain evidence of such a phenomenon, the fact that not so much gas will enter without causing unusually high pressure. Holmboe thinks the risk of a small effusion is that the part of the collapsed lung covered by it can expand again, the liquid not exercising the same control as air or gas. On this view adherence of the two layers would begin below at the costo-diaphragmatic angle and progress all over the pleural cavity. A 1 cm. layer of contracting fibrous tissue would have immense force.

Aetiology and Treatment.

The aetiology of this complication is clearly concerned with that of effusions in general, which, failing sepsis, are due primarily to the bacillus of Koch. This latter, by the nature of the case, is unavoidable, and from the prophylactic point of view we are concerned with contributory causes. Resort to high positive pressures used to be incriminated, but plenty of evidence proves that pleural obliteration can ensue in their absence; in none of my cases had high pressures been used before the effusion appeared. Brauns of Hanover extols the thin needle as preventive of effusions. The most generally invoked contributory cause is exposure to cold. Weinstein⁶ laid great stress on this. Forlanini had, of course, mentioned it. Cionini,⁷ endorsing his view, quotes 12 cases treated in a cold and damp climate, of whom, in a few days, 3 got effusions, while others under better climatic conditions were much more immune. For myself, I entirely believe in the bad effect of cold, and had come to this conclusion before turning up the literature. All my cases of pleural obliteration were being treated in outdoor sleeping shelters (dispensary practice); in a year's sanatorium work I never met with it, nor in dispensary cases treated in a bedroom near an open window. In one instance, a man earning his living, and in his third year of "refills," it followed hard upon a sudden catarrhal attack in very severe winter weather. For this reason I have resolved to do no more pneumothorax work in shelters if any other accommodation is available.

As for treatment, thoracocentesis and replacement of the fluid with gas or air is useless in the long run. Holmgren's method (extolled by Kuthy for dilating small "pockets" of free pleura) of replacing the effusion with sterile salt solution seems worth trying. But the contraction of new-formed fibrous tissue anywhere in the body is obstinate, and to maintain lung collapse extrapleural thoracoplasty will be required, since plugging between the pleura and the chest wall with some elastic non-absorbable solid (*Plombierung*) is clearly too limited a measure. It is a pity thoracoplasty is not a routine operation in this country, as it already is on the Continent. There are many details in connexion with it, and the local anaesthesia necessary is rather complicated, since the needle must reach the intercostal nerves. It would seem essential to success, however.

The operation mentioned needs more attention here. It is essential in initial adherent pleura, where no pneumothorax can be induced; a complication met with as often as every fourth case suitable for lung collapse therapy. With Spengler's modification—operating in two stages, after a preliminary thoracocentesis—it has earned considerable reputation abroad in the treatment of tuberculous pyo-pneumothorax, a complication possible in any artificial pneumothorax where the collapsed lung contains a cavity. Given this attention, and given also precautions against chill, we should be less troubled by this annoying sequela—pleural obliteration.

VERTIGO:

ITS RELATION TO ERRORS OF REFRACTION

BY C. ERNEST PRONGER, F.R.C.S. ENG.,

CONSULTING OPHTHALMIC SURGEON TO HARROGATE INFIRMARY.

VERTIGO is a common everyday malady, and any contribution towards its more successful treatment must be welcome. Mr. Sydney Scott's very interesting paper on this subject in *THE LANCET*, March 6th, 1920, from the aurist's point of view, will prove helpful both to consulting physician and general practitioner. Certain passages also are of great interest from an ophthalmic perspective. He mentions those cases, apparently very numerous, in which both physician and neurologist are baffled in that neither they nor the aurist have been able to discover any definite cause, and asks: "Why is it that we find the cause of the vertigo so difficult to reveal?" The object of this paper is to offer a possible explanation.

The late Dr. Guthrie Rankin once told me in connexion with neurasthenia that nearly all the patients he sent to the oculist were returned with the report that the eyes were normal, or practically so. Now, my experience—not a short one—tells me that it would be rather a rarity to find a case of neurasthenia in which both eyes are normal. May not the same thing happen in vertigo? So many patients have come under my observation in whom this point is borne out that I do not hesitate to suggest this explanation, and will endeavour to substantiate it by a few illustrative cases.

A Case with Varied Diagnoses and Treatment.

The following would appear to be a case in point:—

Patient, male, aged 32, had suffered from severe attacks of vertigo for 15 years, and consulted me in June, 1916. He had seen many specialists, and the vertigo had been variously ascribed to Ménière's disease, neurasthenia, mucous colitis, enlarged heart, &c. He had undergone a great variety of treatment, but although he had seen two ophthalmic surgeons, he was not wearing glasses. I found slight astigmatism in each eye, and advised glasses for constant use, giving the following corrections:—

$$[A. B., \text{aged } 32] \begin{array}{l} R \begin{array}{l} + \frac{75}{5} \text{ ax. } 145^\circ \\ + \frac{75}{5} \text{ ax. } 145^\circ \end{array} \quad L \begin{array}{l} + \frac{75}{5} \text{ ax. } 145^\circ \\ + \frac{75}{5} \text{ ax. } 145^\circ \end{array} \quad \text{Constant.} \end{array}$$

He reported in 1917 that he was much better in every way, felt equal to going to the front, and had had no attack for five months. He called to see me on March 8th of this year in what I may fairly call robust health. I do not claim to have cured this patient by spectacles, for he divides the credit of recovery between the glasses and the manipulations of an "osteopath," who found "some displacement of the cervical vertebrae which was interfering with the circulation in the brain." Fortunately he continued to wear spectacles.

Conclusive Evidence.

The next case is, perhaps, more conclusive. The patient had suffered from neurasthenia with frequent attacks of giddiness for two years previous to seeing me. He also had had much advice and much treatment; glasses had not been suggested. His sight was good; no obvious trouble had called attention to the eyes. There was, however, slight astigmatism, and,

in spite of his great scepticism and prejudice, glasses were insisted upon for constant use according to the formula—

$$\begin{array}{ll} \text{R } -\frac{5}{5} \text{ ax. } 70^\circ & \text{L } -\frac{25}{25} \text{ ax. } 70^\circ \text{ Dist.} \\ \text{[C. D., aged 44]} & \\ \text{R } +\frac{5}{5} \text{ ax. } 70^\circ & \text{L } +\frac{1}{25} \text{ ax. } 70^\circ \text{ Readg.} \end{array}$$

There are many points of interest in the patient's own report:—

You keep, I know, such careful notes of your cases that you only have to refer to mine (June, 1912) to know that I suffered terribly from giddiness and nausea, from loss of memory, buzzing in the ears, and from incapacity to keep my mind centred on any subject long enough to complete the sentence in which I had begun to speak of it. My political work was at a standstill, and I had doubts as to whether I should ever be fit for any work again.

Since I took to glasses I have had only one giddy attack, in July, 1912. From that time my health has steadily improved until when war broke out I was extremely fit. Since then, August 3rd, I have been working at the War Office from 12 to 15 hours daily, and am still feeling well.

Three weeks ago I began to have a recurrence of the old symptoms—that is, I felt my head growing "muzzy," neuritis returned in my left arm. My digestion, too, was getting out of order, with threatening of the giddiness and sickness. I then remembered that I had broken one of my glasses and had had it repaired here in London, and wondered if the lens were accurate and if that could be the cause of my trouble. I changed my glasses and felt better.

I then sent my suspect glasses to your optician whosupplied them originally, and he states that the lens for the right eye is mounted with the front surface to the back, so that the axis of the cylinder is 110° instead of 70° . I have ceased wearing the suspect glasses one week, and already the symptoms are abating.

There could be no clearer proof that my illness, 1910-12, was due solely to eye-strain, and I am deeply grateful to you and the late Dr. Ozanne, who sent me to you."

The error of the optician sometimes brings home to the patient the real cause of his troubles. It also completely answers those ophthalmic surgeons who are sceptical as to the excellent results obtained by the correction of slight refractive errors, and who have asserted that they have been due to "suggestion." There is a tendency to attribute, in these days, nearly all the cases of neurasthenia or nervous breakdown, either directly or indirectly, to the war. In the instance just related the breakdown occurred in 1910, and after being supplied with suitable glasses the patient bore all the stress and anxiety of a very responsible Government post throughout the war with equanimity, and came to see me last autumn in excellent health. In my humble opinion, in many of these cases the starting point or primary cause is slight refractive error, often overlooked.

A Very Severe Case Successfully Treated.

In my next illustration glasses had been prescribed by an oculist for reading only, but as the patient could read easily without them he seldom used them. When I first saw him in 1903 he had suffered for some years from neurasthenia and vertigo, and was in the depths of despair after a long stay in Switzerland without benefit. Afterwards he told me how very near to suicide he had been. In this instance also the return of the trouble was due to an optician's mistake. My prescription was as follows:—

$$\begin{array}{ll} \text{R } -1\frac{25}{25} \text{ ax. } 60^\circ & \text{L } -\frac{1}{25} \text{ ax. } \text{Dist.} \\ \text{[E. F., aged 51]} & \\ \text{R } +\frac{2}{-1\frac{25}{25}} \text{ ax. } 60^\circ & \text{L } +\frac{1}{-25} \text{ ax. } \text{Readg.} \end{array}$$

His report is here given:—

Nov. 24th, 1919.—"Before I saw you in 1903 I had such bad attacks of giddiness that I was often in danger therefrom. Once in London I reeled off the pavement, and only the quick pulling up of the horses by the driver prevented my falling under them, or rather being knocked down by them, for, somehow, I never went down nor entirely lost consciousness. About that time my local doctor took me to see a physician in town, who advised two or three months in the higher residential mountains of Switzerland. But the giddiness was such that I could not go alone, but had to be accompanied by my daughter, who in any place of danger walked between me and it, in case of an attack.

After your prescription for glasses I began to get better, and after some months lost all tendency in that direction and remained free until August of this year. I then had a return of the giddiness, occasionally two or three attacks in the day. Again, after seeing you and the readjustment of my glasses, that condition has passed."

Capacity of Work Restored.

Slight and infrequent attacks of giddiness are usually put down, probably quite erroneously, to indigestion or a "touch of the liver." The more serious ones of which

I am treating may spoil a career or imperil life. Fifteen years of useful work were secured as an alternative to retirement in the case next related. The patient had astigmatism in each eye, apparently overlooked, as he was wearing spherical lenses only. He describes his experiences as follows:—

Feb. 20th, 1920.—"I first consulted you on Sept. 15th, 1904, having been suffering for 10 or 12 years from giddiness, so severe that it was necessary to use a stick in crossing a room. My doctor in Harrogate was inclined to suggest that I should give up my work altogether, but it happily occurred to him that the eyes might have something to do with the trouble, and sent me to you. I had used spectacles for reading for some years, but not for constant use, for although I had tried the prescription of a distinguished specialist (since dead) and he had taken great pains, I had to discard his glasses as useless after a few days' trial.

After I came to you everything was changed. Instead of being an unendurable annoyance, walking, spectacles proved the greatest comfort, so also in regard to reading. With this relief came an extraordinary improvement in the giddiness and a most surprising recovery. I was able to carry on my work, which, as you know, involved the greatest strain on both brain and eyes, and did so with the greatest comfort until last year, at the age of 70, I resigned.

I have never ceased to be grateful to you for the wonderful benefit received at a most critical period of my life, and it has been a pleasure to me to consult you regularly ever since."

Cases Attributed to Variations in Blood Pressure.

Many patients tell me that their giddiness has been ascribed to variations in blood pressure. A patient once said he had been "half killed" by treatment directed towards reducing his blood pressure. A pair of spectacles cured his giddiness in a very short time.

A medical man was once sent to me suffering from neurasthenia, giddiness, and great depression. He feared he had a tumour in the brain. He had recently seen a heart specialist who said the giddiness was due to the condition of his heart, which is described in his letter to me. His vision was quite good, and he had worn no glasses, although he had half a dioptre of astigmatism. I advised glasses for constant use, and

$$\begin{array}{ll} \text{R } +\frac{5}{5} \text{ ax. } | & \text{L } +\frac{5}{5} \text{ ax. } | \text{Dist.} \\ \text{[G. H., aged 47]} & \\ \text{R } +1\frac{75}{+5} \text{ ax. } | & \text{L } +1\frac{75}{+5} \text{ ax. } | \text{Readg.} \end{array}$$

he reported as follows:—

Sept. 11th.—"Since seeing you in June I have had a very busy season, and have got on better than I expected. I am very much better, but cannot say that I am quite myself. Have only had four bad attacks, two on 8th and two on July 9th. These are the only bad ones I have had, but fairly often, on first getting into bed, I had a kind of giddy feeling, not amounting to vertigo. I wear the glasses always, and have got quite used to them."

Again, on Nov. 28th, he writes:—

"Since writing you on Sept. 11th, I am glad to say that I have had only one slight attack of vertigo, and none since. I saw Dr. — again last month, and he found my heart still dilated, and thought there might be some atheroma of the aorta. I was X rayed and they found slight dilatation of the aorta, which I am told is not uncommon at my age, 47. I feel quite comfortable in my glasses, and have never ceased to wear them."

A Final Illustrative Case.

These illustrations might be multiplied exceedingly, but one more ought to suffice for my purpose.

Mrs. A., who lived in Belfast, had suffered for many years from severe and frequent attacks of giddiness, and was, in consequence, unable to go out unattended; had frequently to come out of church, and often had to leave the breakfast table for this reason. She had seen physicians in Belfast, in Dublin, and a neurologist in London, and glasses had been prescribed for her from time to time by different ophthalmic surgeons for reading only. Her vision in the left eye came up to the normal standard, but there was a quarter dioptre of astigmatism, which had either been undetected or treated as too slight to need correction. She was now advised to wear glasses both for distance and reading, giving this prescription:—

$$\begin{array}{ll} \text{R } +1\frac{5}{+75} \text{ ax. } 30^\circ & \text{L } +25 \text{ ax. } \text{Dist.} \\ \text{[Mrs. A., aged 54]} & \\ \text{R } +4 & \text{L } +25 \\ +75 \text{ ax. } 30^\circ & +25 \text{ ax. } \text{Readg.} \end{array}$$

She had at last found relief.

One may well ask: "Why was the cause of the patient's vertigo so difficult to reveal?"

Her letter to me, 12 months later, is as follows:—

"You will be pleased to hear that I have had practically no vertigo, have had no prolonged attack since last July, and even the swift, little turns have not troubled me now for some months. I never have to leave the table, and, indeed, may say that I am practically free, as I go on the roads freely and never feel distressed, so if that continues, I shall be the happy woman I am at present."

Influence of Slight Errors of Refraction on Nervous System.

Two systems of dealing with refraction have hitherto prevailed. The first, which has held sway for generations, aimed at satisfying the visual requirements; and slight errors, less than one dioptré, not being necessary for this purpose, could be ignored. With the exception of headaches, functional neuroses were left to the physician. Some 20 years ago another system began in a small way to gradually assert itself. It included the former one in that it went more thoroughly into detail in meeting visual necessities, but also urged the correction of slight errors as a means of combating many functional neuroses. Scepticism on the latter point brought forth much hostile criticism, but many who were opponents in those days have since become ardently enthusiastic in favour of these views.

Attention was specially directed to this subject in a paper I published in THE LANCET in 1905.¹ Dr. G. M. Gould, the great pioneer in America in this subject, has been a most prolific writer upon it. A good illustration of the change which has taken place in the ophthalmic world is the fact that Dr. Gould was invited to read the opening paper on Refraction at the Oxford Ophthalmological Congress in 1917. What a contrast to the reception accorded to the publication of his "Biographic Clinics."

Conclusion.

I trust that Mr. Scott will be able to gather from the foregoing a possible solution of the difficulty implied in his question; that he will not too readily accept, in any case of vertigo, apart from ear trouble, the statement that the eyes are normal. We all make mistakes, and so many patients have been cured by glasses, whose eyes had previously been said to be normal. That the defect is too slight to need correction should be accepted only with the greatest caution.

Doubtless there are many ophthalmic surgeons still unconverted who continue to follow the earlier methods of dealing with refraction cases, and also many who have not yet had sufficient experience and success to ensure getting the best possible results in treating the many functional neuroses of which vertigo is a common one.

At any rate, there is plenty of room with all of us for more skill, more accuracy, more thoroughness, more perseverance, and, may I add, more enthusiasm.

Medical Societies.

OXFORD OPHTHALMOLOGICAL CONGRESS.

THE eleventh annual meeting of the Oxford Ophthalmological Congress was held at Oxford from July 14th to 16th in the department of human anatomy of the museum, kindly lent by Professor Arthur Thomson, whilst members again enjoyed the hospitality of Keble College. The attendance was large, including from overseas Professor Harvey Cushing, Dr. Luther C. Peter (Philadelphia), Professor Van der Hoeve (Leyden), Professor S. Holth (Christiania), and Dr. S. Lewis Ziegler (Philadelphia).

WEDNESDAY, JULY 14TH.

On the first day a discussion on Perimetric Methods was opened by Dr. LUTHER C. PETER, who limited his remarks to the newer methods of perimetry and the type of cases for which they were especially adapted. After pointing out the inefficiency of the ordinary perimeter in recording changes in the central zone the opener proceeded to discuss the various modern instruments specially adapted for this purpose. Dr. Peter then urged a change in the nomenclature from linear measure in millimetres to angle subtended in degrees or minutes, and discussed the size of the test object, especially for colour studies. The size for the central

zone should subtend an angle of half a degree and that for the peripheral zone one degree. The special methods required for the study of bilateral central scotomata were (a) by making use of muscle sense, and (b) by the speaker's method of combining perimeter and campimeter.

A discussion followed, in which the following took part: Professor VAN DER HOEVE, Mr. A. H. SINCLAIR (Edinburgh), Dr. MARX (Leyden), Professor CUSHING, Professor HOLTH, Mr. E. H. E. STACK (Bristol), Lieutenant-Colonel R. H. ELLIOT (London), Dr. A. MAITLAND RAMSAY (Glasgow), Major L. E. J. Lister, I.M.S., Mr. T. HARRISON BUTLER (Leamington Spa), Mr. BURDON COOPER (Bath), Mr. E. E. MADDOX (Bournemouth), Mr. P. G. DOYNE (London).

Dr. MARX showed an ingenious test object for use with his perimeter consisting of a small steel ball moved by an electro magnet applied to the back of the screen, whilst Professor HOLTH exhibited three patterns of a chord pocket perimeter of his own design.

THURSDAY, JULY 15TH.

On the second day the Doyme memorial lecture was delivered by Mr. F. RICHARDSON CROSS (Bristol), who took as his subject the Nerve Paths and Centres Concerned with Sight. After paying a tribute to the founder of the Congress, the late Robert Walter Doyme, the lecturer dealt in a comprehensive manner with visual tracts and centres, comparing certain areas with the homologues in monkeys, birds, reptiles, &c. A number of interesting slides were shown of the field of vision in quadrant hemanopia and cases of injury of the occipital cortex bearing out the more recent views on the relationship between the peripheral visual fields and the centres in the occipital area.

At the conclusion the lecturer received the Doyme memorial medal for 1920.

Papers were read by Mr. A. S. PERCIVAL (Newcastle-on-Tyne) on Light Sense, with some practical deductions drawn from its consideration; Professor VAN DER HOEVE on Eye Symptoms in Tuberos Sclerosis of the Brain, an extremely interesting and valuable contribution to the present knowledge of the disease; Mr. MAURICE BARTON, an Examination of the Eyes of Pit Ponies, particularly with reference to miners' nystagmus.—Dr. A. HUGH THOMPSON read a paper on Physiological and Glaucoma Cups, in conjunction with one by Dr. RAYNER D. BATTEN, entitled "Premonitory Symptoms of Glaucoma, (1) Deep Tension, (2) Excavation of the Optic Disc."—Dr. ZIEGLER'S paper on the Ocular Menace of Wood Alcohol Poisoning attracted attention, as also did a fascinating contribution by Dr. LOUIS SAMBON entitled, "Ancient Eye Instruments."

Discussion on the papers was unfortunately limited by the length of the programme.

On the afternoon of the second day the Congress adjourned to the Eye Hospital, where short papers were read on operations, new instruments, and ophthalmic apparatus, as follows:—

Lieutenant-Colonel H. HERBERT on the Indications of Glaucoma Operations, four illustrative cases being shown.—Professor HOLTH described a new punch-forceps sclerectomy for glaucoma.—Mr. N. C. RIDLEY showed a patient whose orbit he had successfully restored by a plastic operation and who was consequently able to wear an artificial eye.—Dr. BATTEN demonstrated the hydrophthalmoscope on a patient and indicated its value clinically.—Mr. PERCIVAL showed some simple devices for estimating the light-sense. All the contributions were freely discussed.

Museum and Festivities.

In the Scientific Museum, which was open during the Congress, Mr. STACK showed a simple and ingenious motor trephine which should prove of considerable aid in the operation of trephining. Mr. R. J. E. HANSON (London) showed a well-designed ophthalmic bureau and equipment for R.N. oculists serving at either a Royal naval hospital, a dépôt, naval base, or fleet at sea, and also drawings and models of improvements in gun-sighting telescopes, theodolites, and microscopes.

¹ THE LANCET, June 10th, 1905. Slight Errors of Refraction and their Influence on the Nervous System.

—Mr. MADDOX showed (1) an artificial epistaxis knife; (2) illuminated forceps; (3) the "V" test for astigmatism.—Mr. RIDLEY showed a new cataract knife.—In a separate room Professor Barr's optophone was demonstrated. In the Commercial Museum instruments, apparatus, lenses, and books were on view during the meeting.

At the close of the proceedings on the first day a general meeting was held, after which members with their friends met at Queen's College for tea, the Rev. S. B. Cronshaw acting as host. The official dinner of the Congress took place on Thursday evening in the hall of Keble College.

SOCIÉTÉ DE THERAPEUTIQUE DE PARIS.

AT a recent meeting of this society Dr. BENSUADE and Dr. HALLION communicated a paper on the Treatment of Asthmatic Attacks by Adrenalin and Pituitary Extract. They stated that two different views were held as to the pathogenesis of asthma, some writers maintaining that it was due to bronchial spasm, and others to vascular turgescence of the alveoli. The two views, however, were not incompatible with one another, for while adrenalin caused a relaxation of the bronchial spasm pituitary extract in small doses caused a fall of blood pressure and relieved the pulmonary congestion.

In a paper on Gastro-intestinal Disturbances of Psycho-neurotic Origin and their Treatment by Psychological Re-education Dr. P. E. LEVY recorded various cases of gastric or intestinal disorders which had been treated for several years by ordinary methods without effect, but were rapidly cured when the underlying moral or psychological causes were recognised and received appropriate treatment.

In a paper on Intravenous Injection of Iodine Oil, Dr. F. RATHERY and Dr. J. CARTIER stated that after experiments on horses they had given intravenous injections to patients suffering from various diseases, such as chronic rheumatism, syphilitic arteritis and lethargic encephalitis, without any bad effects and with decidedly better results than had been obtained in the same patients by ingestion of potassium iodide. The doses consisted of $\frac{1}{2}$ –1 c.cm. of lipiodol, the injections being given every week or fortnight.

In a note on the Treatment of Hæmorrhoids by Cupressus Sempervirens, Dr. H. LECLERC stated that the use of the cypress as a hæmostatic and astringent dated from the time of Hippocrates. The preparations which were to be recommended were the fluid extract, the tincture (20–30 drops twice a day before meals) or the soft extract (0.15–0.20 g. daily). The fluid extract, or 5 per cent. tincture, could be applied externally, and also the soft extract in the form of an ointment or suppositories, each containing 0.15 g. of the active principle. All cases so treated showed an attenuation of their inflammatory symptoms, and cessation or diminution of hæmorrhage, pain, and spasm of the sphincter.

In a paper on the Treatment of Gastric Syphilis Dr. G. LEVEN stated that many medical men were ignorant of gastric syphilis and its effects. Before making the diagnosis of cancer of the stomach the practitioner should always think of syphilis and try the therapeutic test, whatever the Wassermann reaction might be. Dr. Leven's treatment was as follows: first day, intramuscular injection of 0.02 g. of biniodide of mercury; second day, mercurial inunction; third day, mercurial suppository; fourth day, another injection; fifth day, inunction; sixth day, suppository, and so on until the twenty-first day, except that the inunction was given only five times, an injection or suppository being substituted when four inunctions had been given. When the period of 21 days' treatment was completed the patient was given 15–20 days' rest and then a second or third series, if necessary, was ordered. Three grammes of iodide of potassium were given daily simultaneously with the mercurial treatment. Arsenical compounds were not employed.

Reviews and Notices of Books.

THE SHIBBOLETHS OF TUBERCULOSIS.

By MARCUS PATERSON, M.D., Medical Superintendent, Metropolitan Asylums Board, Colindale Hospital; late Medical Superintendent, Brompton Hospital Sanatorium, Frimley; Medical Director, King Edward VII. Welsh National Memorial Association; Resident Medical Officer, Brompton Hospital. London: John Murray. 1920. Pp. 239. 10s. 6d.

WITH regard to the insane, medical men are ready to admit the superiority of institutional over home treatment, and to concede to the alienist the qualifications of a specialist better equipped than themselves to treat insanity successfully. At present the position with regard to pulmonary tuberculosis is very different. It is a disease every practitioner treats, and the aid of the specialist is seldom invoked till the disease is incurable. One reason for this state of affairs is the belief, still prevalent, that when plenty of fresh air, milk, eggs, butter, and rest or exercise have been prescribed, little further need, or can, be done. Dr. Paterson's book will come as a rude shock to the exponents of this comfortable creed. He gives the Encyclopædia Britannica definition of shibboleth as: "A catch phrase or cry to which the members of a party adhere after any significance or meaning which it may have imparted has disappeared," and, as an example, he quotes H. R. Reynolds: "Christians were ready to insist on that insensate shibboleth: Except ye be circumcised, ye cannot be saved."

To readers whose knowledge of pulmonary tuberculosis is derived from the platitudes of most text-books and the perfunctory teaching of this subject in many general hospitals the author's book will be little short of a revelation. One after another of the stock teachings of an older generation are irreverently pulled down from the safe niches which the passage of time has left high and dry. Some of these relics are dusted, patched up, and replaced, but many are mercilessly consigned to a damnation unrelieved by the faintest praise. It is impossible to follow this process of destruction without becoming infected with some of the author's glee over the bonfire. It is really amazing that so many myths concerning tuberculosis should still exist.

In each of the 59 chapters a shibboleth is dissected. The author begins by exposing the folly of sterilising milk without heeding germ-laden butter and cheese. He also stamps as shibboleths that (1) cod-liver oil is necessary in the treatment of tuberculosis; that (2) exertion causes hæmoptysis; that (3) cold foods and drinks are necessary for the treatment of hæmoptysis; that (4) a tuberculous empyema should be opened and a tuberculous larynx scraped; and that (5) a change of climate is good for tuberculosis. The promoters of farm colony schemes will hardly be flattered to find their progeny superannuated as shibboleths, but they may find comfort in the reflection that the author's alternative scheme—a garden city for tuberculosis—is first-cousin to the farm colony. Of the value of sanatoriums the author has no doubts, and a recent criticism of them by Dr. L. Cobbett is mercilessly ridiculed. Cobbett's statements are interpreted by the author as meaning that "..... in plain language one of the surest ways to stamp out tuberculosis would be to hasten the deaths of all tuberculous persons. There can be no doubt that to kill every person having tuberculosis would be quicker still." The half-truth—"once tuberculous, always tuberculous"—is parodied by the author's rendering: "once a patient has had pulmonary tuberculosis, he is never allowed to suffer from any other disease."

It would be very hard to overrate the value of this book. Yet here and there the author kills shibboleths only to replace them by others; as, for example, when he insists on divorcing treatment of the disease from

training of the patient for a suitable profession, or when he recommends morphine in hæmoptysis. But these are minor details, and the book, as a whole, is as sound in its teaching as it is pungent and entertaining in its style.

DIE DEUTSCHE CHIRURGIE IM WELTKRIEG 1914 BIS 1918.

Herausgegeben von AUGUST BORCHARD, Professor in Berlin-Lichterfelde, und VICTOR SCHMIEDEN, Direktor der kgl. chirurgischen Univ.-Klinik, Frankfurt a.M. Leipzig: Johann Ambrosius Barth. 1920. Two vols. Pp. 938. M.102.

THROUGHOUT the war it was widely stated and believed that German war surgery was greatly inferior to that practised by French and British surgeons. Sometime we shall know to what extent this was true, but German surgeons were not guilty of all the barbarities attributed to them. Shortage of materials compelled them to resort to the use of inferior substitutes, which handicapped them in their work to an extent it is still difficult to realise in spite of the ocular demonstration provided by the condition of returned prisoners of war. This much it is necessary to remember.

We have now the means of roughly comparing German surgery as a whole with ours by this large and impressive text-book in two volumes, edited by Professors August Borchard of Berlin and Victor Schmieden of Frankfurt. It is, of course, difficult to judge after the event how efficiently the work was carried out in the average field hospital, but the impression produced by a perusal of these volumes is that German methods were, on the whole, though with important exceptions, not widely different from ours. They were faced with precisely the same problems, and they seem in most cases to have arrived at the same solutions. No doubt the literature of French and British war surgery was available on the other side of the line, and the German is a past master at extracting the best from other people's ideas. But if German war surgery owes anything to the Allied nations, the debt remains unacknowledged. True, the Carrel-Dakin treatment is described, but we have searched in vain for other reference to French or British authorities.

The whole field of war surgery, including late treatment, is difficult to compress into 900 pages, and the attempt to be exhaustive has resulted in an inequality which is sometimes ludicrous. An example of this is to be found in the page devoted to the condition of "chyllothorax" following wounds of the thoracic duct. Another is the tendency to give quite worthless statistics; it can hardly serve any useful purpose to state that, of 309 wounds of the penis, 41 were mortal, without specifying the other wounds that accompanied them. All war statistics are apt to be misleading owing to the presence of incalculable factors. The German claim, however, that in penetrating wounds of the abdomen 40-50 per cent. of the cases operated upon were saved seems a modest one. During the last year of the war the percentage of recoveries in British hospitals was considerably higher than this. An advantage of the exhaustive method is to be found in an interesting chapter on self-inflicted wounds, which we do not remember to have seen separately described in any text-book in English.

In trying to form an independent estimate of German surgical efficiency we turned naturally to three topics of outstanding importance—the treatment of gas gangrene, of shock, and of fracture of the femur. It was rumoured, as widely as the uncomplimentary rumours referred to above, that during the war the Germans had been more successful than ourselves in the search for an efficient serum with which to combat gas gangrene. And we find that, in the present work, emphasis is laid on the use of a polyvalent bactericidal (not antitoxic) serum; it is even recommended that it be given prophylactically at the same time as the antitetanic serum, which was used in the German army, as in ours, for every wounded patient. Here they seem to have been in advance of us; but we should like to know more of the

results. In the other two test subjects it is pretty clear that we outstripped the Germans in the race for efficiency. Judging by what the Berlin and Frankfurt professors have to say, the causes and treatment of shock do not seem to have been extensively studied or understood. The extremely inadequate account of blood transfusion that is given suggests that this vital method was very little practised; and other substitutes for saline infusions, such as gum solution, are barely mentioned. In the description of the treatment of fracture of the femur no place has been given to the Thomas's splint; we should not expect to find it referred to under that name, but it does not seem to have been used at all. Instead, plaster bandages, with windows cut in them at the site of the wounds, commended themselves to the writer of this chapter, and we receive an impression of rough and ready methods. We cease to wonder at the condition of returned prisoners of war. In the after-treatment of their own wounded, extension seems to have been applied largely by means of nails or some equivalent driven into the bone, and no contrivance, such as Pearson's callipers, resting lightly on the bone, is described or figured. If for the purpose of fixing a fractured femur during transport the Germans had any method as good as that of Thomas, it fails to emerge from the volume before us.

The book is well produced and illustrated. The handsome cloth binding deceives the eye at first, but on looking closely we see that, except for the back and corners, it is made of a cloth substitute.

ANNALS OF MEDICAL HISTORY.

New York: Paul B. Hoeber. September, 1919. Pp. 213-304. \$2.50.

THE publication of this part has been delayed by difficulties in printing. The papers are of much interest. One is an appreciation of Bence Jones, another deals with the accounts of Felix Platter, the well-known Basle physician of the sixteenth century. His accounts show that in 54 years he made £120,020. Basle pounds that is, which would amount in modern money to about £25,000, but of course the purchasing value of money in the sixteenth century was far higher than to-day. Besides his purely professional occupations Platter increased his income by the breeding and sale of silkworms, silk, and canaries. Perhaps the most interesting paper in the number is that by Dr. John Foote called "Ancient Poems on Infant Hygiene," dealing with two sixteenth-century poems, the one by Tansillo, called "The Nurse," and the other by Scève de St. Marthe, called "Pædotrophia." Didactic poems are always good reading, and perhaps no other class of literature shows such wide divergences. Compare the beauty of the "Georgics" and the austere majesty of the "De Rerum Natura" with Dr. Grainger's poem on "The Sugar Cane"; or, to take an even worse poem, with the astonishing drivel of Solyman Brown's "Dentiaid." Bad as this latter was though, its advice is sound.

"Whene'er along the ivory disks are seen
The rapid traces of the dark gangrene,
When caries comes, with stealthy steps to throw
Corrosive ink spots on these banks of snow,
Brook no delay ye trembling suffering fair,
But fly for refuge to the Dentist's care."

The poems discussed by Dr. Foote are on a much higher level than Mr. Brown's, and the hygiene of them is excellent; the therapeutics and the physiology are naturally not in accordance with modern ideas.

Great interest was taken in infant hygiene in the sixteenth century in France owing to the lessening of population brought about by the civil wars, while in the eighteenth century in England reform of infant mortality and the treatment of children's diseases were beginning to be considered as desirable. Both Tansillo's poem and that of St. Marthe were translated into English 1797-98—the one by William Roscoe, the other by Dr. H. W. Tytler, though a previous translation of Pædotrophia by N. Rowe had appeared in 1710. Rowe also translated another poem by the Abbé

Quillet called "Callipædia, or an Art How to Have Handsome Children," so that any married couple equipped with these three volumes could not plead ignorance of either pre- or post-natal hygiene. Despite the astonishing folk lore of all three poems, there is a great deal of instruction which is quite unexceptionable and which might well be impressed upon both expectant and actual mothers to-day.

Another interesting paper is that by Dr. Pleadwell, being an account of William Paul Crillon Barton, an ardent reformer in the American Naval Service, who was born in 1786. He seems to have been a genius, but if the portrait of him which is reproduced is a good likeness, we must agree with a contemporary who pronounced his style of dress "equally unnatural and eccentric."

DENTISTRY.

By BAYFORD UNDERWOOD. London: J. and A. Churchill. 1920. With 10 illustrations. Pp. 216. 9s. 6d.

WITHIN the space of a little over 200 pages Mr. Underwood has contrived to compress the essential facts of dental anatomy and dental surgery. The book should be of value to the student who, having mastered his subject from the standard text-books and his hospital practice, wishes to refresh his memory just before undergoing the ordeal of examination.

EVERYDAY MOUTH HYGIENE.

By JOSEPH HEAD. London: W. B. Saunders Company. 1920. Illustrated. Pp. 63. 5s.

The object of this small book is to enable "loving mothers and conscientious nurses" to acquire a knowledge of the principles of mouth-cleansing. The author starts by describing with the aid of diagrams the morbid conditions usually known by the terms pyorrhœa alveolaris and caries, and impresses on his readers that these conditions can be prevented by the regular removal of the bacteria from the surfaces of the teeth. He considers that in the use of floss silk and the tooth-brush lies the salvation of the race from dental disease.

In a book written for the laity we are disappointed to find no reference to the influence of diet on the dentition, or to the importance of nasal breathing and of active function of the teeth. The prevention of dental disease will not be accomplished by the employment of artificial methods, but by a recognition of the fundamental principles underlying the physiology of mastication. The book is well illustrated, and the methods of cleansing the teeth clearly described.

AIR SICKNESS: ITS NATURE AND TREATMENT.

By R. CRUCHET, Professor of Medicine in the University of Bordeaux, and R. MOULINIER, Naval Surgeon. Translated from the French by J. ROSSLYN EARP, M.A., M.R.C.S. London: John Bale, Sons, and Danielsson. 1920. Pp. 96. 5s.

It is a pleasure to be able to welcome this excellent translation of MM. Cruchet and Moulinier's little book. The whole question of the investigation of the physical fitness of pilots, and of the special disabilities that result from flying, is so important, that it is very stimulating to have the views of our French colleagues set before us. The writers emphasise the rise in diastolic pressure that is found after a flight, and attribute it to vascular changes induced by the rapid alterations in the atmospheric pressure, since they have found it greater when the descent has been very rapid. They compare the effect of flights with the changes in blood pressure induced by violent exercise. The results that they report seem to us to be explicable as an after-reaction to the low diastolic pressure which exists during the flight, as they themselves have shown, and which English and American workers have found may be produced by mere exposure to low oxygen tensions, and we do not consider that they have sufficiently disposed of the arguments of their opponents, MM. Marchoux and Nepper, who attribute

almost the whole effect of a rapid descent to the pressure differences set up in the ear. When one considers the effects that may be produced on the vascular system by vestibular stimuli, as, for instance, in seasickness it is difficult to exclude this factor. Mere slight fatigue and the reactions which follow emotion are also probably contributing factors and receive some, though in our opinion insufficient, consideration. There is one misprint on p. 89, since it is clear that Valsalva's manœuvre should have been recommended for descents, and Toynbee's for ascents and not vice versa.

This book may be safely recommended to all those who are interested in the medical problems of flying, since the authors develop their arguments well, even when dealing with very controversial points, and include valuable advice on the hygiene of flying men.

GOD'S PRICE.

By MAUDE LEESON. London: George Allen and Unwin, Ltd. 1920. Pp. 314. 7s. 6d.

HAD Miss Leeson devoted less space and care to propounding her philosophy that "God's debts are not to be settled cash down," she might have written a less tedious and more artistic story of the subsequent meeting and reunion of a divorced couple. She has missed an opportunity of producing a valuable work, for she observes well and lacks many current affectations in literature on the subject of love and marriage.

THE DIARY OF A POLICE SURGEON.

By GRAHAM GRANT. London: C. Arthur Pearson, Ltd. 1920. Pp. 188. 3s. 6d.

THIS is a selection of the more arresting episodes in an East-End practice extending over some 30 years. We can recommend it to all as an example of canny observation; to the medical student as supplying that touch of reality without which forensic medicine is merely a phantasy of the legal mind obsessed; and to the layman as a dramatic tale of life, after reading which he can no longer wonder at the popularity of the Lyceum productions. In our police surgeon we early suspected his relish of a "really good fight!"

BRIGHTNESS AND DULLNESS IN CHILDREN.

By HERBERT WOODROW, Ph.D. London: J. B. Lippincott and Co. 1919. Pp. 322. 6s.

THIS book by the associate professor of psychology in the University of Minnesota suggests that whilst we are more or less at a standstill in England there is a steady and continuous advance in educational research in America, of which the author gives a review. The earlier part of the work is of medical interest, dealing as it does with the graded status of the individual, reckoned from the chronological, mental, anatomical, and pedagogical age, with the relations of these gradings and with their value for assessment as to the future work of the individual child.

The rapid growth of the brain in pre-school age is well illustrated by a diagram, stated to embody the most recent research, but reminiscent of that published by Donaldson 25 years ago. Eruption of the teeth is taken as the best criterion of anatomical age, but unfortunately, although the author is apparently aware that girls have, on the average, one tooth more than have boys of the same age, there is no sex discrimination in the table given. The ossification of wrist bones has also been put forward as a means of determining age, but it is still doubtful whether this can be as universally accepted as the author suggests. However, he builds up a clear and concordant picture showing that anatomical age, however measured, correlates to mental ability, and that, whether the brightness of the child be high or low, the rapidity with which his mental growth is completed correlates with his anatomical age. When the latter is less than the child's chronological age the author advises that attention should be directed primarily to his health. But physical defects are far from being

the chief factor in school retardation. Evidence of mental superiority over the boy is more than accounted for by the girl's superiority in anatomical age. What Roberts showed in THE LANCET¹ 35 years ago for the group of girls above puberty Dr. Woodrow demonstrates for those below that age. The school standard is found to be a little too high for the average, so that the majority fall behind. Girls, however, make more progress than boys. The evidence of early fixation of the child's capacities even before school age is also reviewed. The uselessness of effort to educate the duller is emphasised, for if a child's intelligence quotient (the mental age divided by the chronological) is below 0.7 arithmetic, except of the very simplest, is out of the question, and if it is below 0.4 instruction in reading is hopeless. Taking children as a whole, 10 per cent. are subnormal and 4 per cent. supernormal, so that something more than ordinary schooling is a necessity in many cases.

The book is mainly taken up with psychological assessments of children, and may be read both as an indictment of our scholastic system and a guide to the way out.

TASCHENBUCH DER AUGENHEILKUNDE FÜR ÄRZTE UND STUDIERENDE.

Fourth edition. By Dr. CURT ADAM. Berlin and Vienna: Urban and Schwarzenberg. 1920. With 72 figures and 5 plates. Pp. 400. M. 66.

THIS book, the first edition of which was published in 1908, is addressed to the German-speaking practitioner, and presumably contains so much of the theory and practice of ophthalmology as he is expected to know, indicating the cases in which the help of the specialist should be called in. External diseases occupy the bulk of the book. The bacteriology of conjunctivitis finds a place, and so does the differential diagnosis of external muscular paralysis. On the other hand, all diseases of the fundus are left severely alone and the ophthalmoscope is not even mentioned. Even refraction is only dealt with by the description of subjective tests. The retinoscope is presumably an instrument for the specialist. No operative procedures are described except the simple ones that usually fall to the lot of the general practitioner. There is, however, a copious list of formulæ for prescriptions and references to various other methods of treatment. In this country a book purporting to be a handbook on diseases of the eye, limited in the way that has been indicated, would hardly be acceptable. The deplorable economic conditions now existing in Central Europe, one result of which is that even such a small book as this is priced at what would seem to be a prohibitive figure, may account for much.

JOURNALS.

Journal of the R.A.M.C.—In this journal for June Dr. Woodcock completes his notes on Malaria in Palestine. Of fresh infections those in the early part of the year are predominantly benign tertian (82 per cent.), with a maximum in July; malignant tertian began to rise very rapidly in September, and in October had its own maximum and was then far more prevalent (86 per cent.) than the benign. In Palestine infections were massive, and malignant tertian parasites were so numerous in the films that this infection could be quickly diagnosed; often several parasites were seen in the first microscopic field. Intravenous injections of 12 gr. of bihydrochloride of quinine in 10 c.cm. normal saline injected slowly through a very sharp fine needle, 1 c.cm. in half a minute, and repeated twice daily for two days, had more effect on the disease, and with less inconvenience to the patient, than any other treatment which he saw there.—Major C. T. H. H. Harold tells how he met, traced out, and stopped an epidemic of tick fever in Persia. It was spread by *Argas persicus*, a bed bug. Men were infected in dirty caravansaries and with relapsing fever, not of the Indian but of a Persian character, resembling the relapsing fever of East Africa. The disease yielded to injections of neo-salvarsan.—Captain J. A. Glover, O.B.E., with a statistical account of some 250 cases of cerebro-spinal fever, shows that while the

average death-rate was about 44 per cent., one group of 37 cases, which was lucky in coming under treatment with a new serum, in consequence had only four deaths in all—a 12 per cent. mortality—Lieut.-Col. E. P. Sewell, C.M.G., D.S.O. and others discuss an outbreak of food poisoning in 31st General Hospital at Port Said on Jan. 19th and 20th, 1917, with 473 cases and three deaths. It attacked mainly the patients but also a few of the orderlies. The infected food was probably the tinned milk used in the tapioca pudding and the tea, and it was probably in some way infected after the tins were opened, but the exact causation remains obscure, in spite of the careful investigation that was made.

Journal of Neurology and Psychopathology, Vol. I, No. 1.—Dr. William McDougall, of Oxford, contributes a paper dealing with suggestion and its definition. His amended definition is couched in the following terms: "Suggestion is a process of communication resulting in the acceptance with conviction of the communicated proposition independently of the subject's appreciation of any logically adequate grounds for its acceptance." He explains the assertion of Professor Janet and others that they can hypnotise only neurotic subjects and that the patients, when cured, can no longer be hypnotised and are insuggestible, by pointing out that this experience depends on the degree of self-assertiveness of the patient; if the operator invites the intelligent help of the subject, explaining to him the nature of the process, Dr. McDougall says it will be found that his resentment is not aroused, there is no desire to assert his independence over against his would-be hypnotiser, and that with good and sufficient reason successful coöperation with the physician is always possible.—Dr. Worster-Drought contributes a useful and practical article on the Treatment of Cerebro-spinal Fever, which can be recommended as a thoroughly up-to-date presentation of a subject which has undergone considerable modification as the result of war experiences.—Dr. Parkes Weber sends a paper on Thinking and Dreaming, and the Freudian explanation of dreams, based on interesting evidence culled from what was supposed to "constitute life" amongst ordinary sensual individuals in bygone times. His contention is that the Freudian teaching that nearly all dreams have a sexual explanation is most unlikely to be true, or that the element of truth in it is so exaggerated as to appear preposterous.—Dr. George Watson, of Rainhill, records in some detail the pathology of a case of encephalitis lethargica involving mainly the cerebral cortex.—There are shorter papers by Dr. Douglas Firth on Cerebellar Fits of the Hughlings Jackson type, by Dr. R. M. Stewart on Hypotonia in General Paralysis, and by Dr. Graham Brown on the Phenomenon of Heteresthesia in a case of Spinal Concussion.—A particularly useful critical review on Vagotonia, by Dr. Alfred Carver, is also worthy of mention.

LONDON HOSPITAL MEDICAL COLLEGE.—On Monday, July 5th, the prizes and certificates were distributed to the successful candidates of the Medical College of the London Hospital for the session 1919-20. The distribution was made by Dr. Robert Hutchinson, a physician to the hospital and member of the College Board. The following is the list of the scholarships and prizes awarded: "Price" entrance scholarship in Science, £100, Mr. L. Mushin; Second entrance scholarship in Science, £50, Mr. H. Taylor; "Price" university scholarship in Anatomy and Physiology, £52 10s., Miss C. M. Otley, of the University of Oxford. Medical prize, £20, Mr. D. Hunter; prize in Clinical Obstetrics and Gynaecology, £20, Mr. M. C. Hartley; honorary certificates, Mr. J. R. Zeitlin and Miss M. E. Kennedy. "Andrew Clark" prize in Clinical Medicine and Pathology, £26, Mr. D. Hunter; honorary certificates, Mr. P. Steinberg and Mr. F. H. W. Tozer. Surgical prize, £20, Mr. D. Hunter; honorary certificates, Miss M. E. Kennedy. "Anderson" prizes in Elementary Clinical Medicine, £3 each: (1) Miss D. J. Fox; (2) Miss D. Gibson; (3) Mr. F. H. Mather; honorary certificates, Mr. H. D. Lawson, Miss H. R. Ashton, Miss D. S. Russell, and Miss E. M. Dixon. In-patient-dresser's prizes, £5 each: (1) Mr. C. S. Cloake; (2) Miss D. Gibson and Mr. W. Thomas, equal, prize divided; (3) Miss H. R. Ashton; (4) Miss G. H. Jones; honorary certificates, Miss G. Denham and Miss D. S. Russell; Practical Anatomy, £6 prize, Miss S. H. G. Robinson; £2 prize, Mr. P. H. O'Donovan; £2 prize, Mr. A. J. Reed; honorary certificates, Mr. D. R. Blunn, Mr. G. N. Golden, Mr. S. A. Grant, Mr. K. W. Todd. "Letheby" prizes, £15 (Organic Chemistry), Mr. R. T. Brain; honorary certificates, Mr. L. Mushin; £10, Chemical Pathology, Mr. C. S. Cloake; honorary certificate, Mr. F. C. Hunt. "Sutton" prize, Pathology, £20, Mr. M. Buxton; prize in Anatomy and Physiology, £31 10s., Mr. G. N. Golden; honorary certificate, Miss D. Peake. "Arnold Thompson" prize in Diseases of Children, £15, Miss O. G. Potter; honorary certificates, Miss D. J. Fox, Miss M. E. Kennedy.

THE ROYAL SANITARY INSTITUTE: BIRMINGHAM CONGRESS, JULY 19TH-24TH.

THE thirty-first annual Congress of the Royal Sanitary Institute was held in Birmingham from Monday, July 19th, to Saturday, 24th, Lord ASTOR presiding. 12,000 members and delegates attended, this number having only once been exceeded—namely, at Glasgow in 1904.

PRESIDENT'S ADDRESS.

Viscount ASTOR delivered his presidential address at the inaugural meeting on Monday. He gave a broad survey of the relation of government to public health, and declared that under present circumstances local government—i.e., administration and government by elected representatives—was at stake. He was optimistic of the future, but warned the public that the only alternative was the growth of a bureaucracy. The place of those who wished to serve the community was on the councils, and they must not be content to act merely as members of voluntary associations. He made a strong appeal for the best men and women to come forward to serve in this capacity. He emphasised the importance of moulding public opinion; governments could not legislate far in front of public opinion. The various functions and problems of the Ministry of Health were touched upon. Housing at the moment was, he said, the primary concern; a high ideal had been set up, and there was a vast field of work to be explored. He was hopeful of the sequel to the free entry of women into new fields of endeavour.

It is interesting to recall that at the Birmingham Congress in 1898 Sir Joseph Fayrer advocated the institution of a Ministry of Health, and that upon its next visit the Congress finds this former ideal an accomplished fact.

During the week five sections met regularly, being devoted to: (a) Sanitary Science and Preventive Medicine; (b) Engineering and Architecture; (c) Hygiene of Maternity and Child Welfare; (d) Personal and Domestic Hygiene; (e) Industrial Hygiene.

THE SECTIONS.

In the *Section of Preventive Medicine* Sir ROBERT FIRTH, on Tuesday, in his presidential address attempted to strike a balance-sheet of the national health. On the one side the expectation of life has, he said, increased in males from 41 to 51 years and in females from 44 to 55; the infant mortality rate is well below 10 per cent.; we suffer a relatively light burden from some epidemic diseases and many gross forms of disease have practically disappeared; while whole groups of tropical diseases are coming under control. On the other side, there is a steadily falling birth-rate, an unnecessary loss of life in infancy and before birth, nearly 100,000 new cases of tuberculosis annually, a similar number of cases of diphtheria and scarlet fever, and upwards of a million cases of measles. Further, one-sixth of the children of school age are too dull mentally to derive reasonable benefit from schooling; half are in need of dental treatment. More than half the people under the Insurance Act claim and receive treatment representing an aggregate loss of working time equal to thousands of years per annum. The Garden City he regarded as the product of a confusion of ideas and as giving us doll's house plots and a series of pocket squares of mown grass. He thought our towns should contract in place of expanding and rise instead of spreading. He advocated a closer coöperation between the whole-time public health officers and the general practitioner. The administration of the Public Health Acts had not only failed to attract the sympathetic coöperation of the practitioner, but sometimes tended to divorce his interest from the work.

Dr. G. A. AUDEN discussed the provision of institutions for the mentally defective and enunciated the main principles essential for their success.—Dr. W. A. POTTS, who is psychological expert to the Birmingham magistrates, urged the importance of psychic clinics.

A discussion on the Falling Birth-rate: Is it to be Deplored? was opened by Dr. KILLICK MILLARD. The birth-rate reached its maximum of 36 per 1000 in 1876, since when it has continuously declined, until in

1914 it was 22·8, a reduction of 37 per cent. Dr. Millard considered the question in relation to food-supply, over-population, and fuel-supply, and decided that a reduction in the birth-rate was a wise, civilised, and economical method of meeting the situation.—Dr. P. BOOBYER (Nottingham) and Dr. S. G. MOORE (Huddersfield) took the opposite view, the latter foreseeing that if we restricted and other nations did not we should be simply overwhelmed.—There was an animated discussion, revealing a sharp division of opinion.

On Wednesday Colonel R. J. BLACKHAM, A.M.S., read an important paper advocating the claims of dried milk. He described the effects of drying upon the milk and pointed out that it still contained vitamins. Being sterile, it is especially useful for infants, notably in the tropics. It also had a great field of usefulness in various disease conditions.—The claims made were strongly supported by several medical officers of health who had used it in infant welfare centres, only one speaker preferring ordinary cow's milk for this purpose.—Professor H. R. KENWOOD advocated the control of the sale of disinfectants, and a resolution was passed demanding that liquids sold as disinfectants should be graded, the lowest having a carbolic coefficient of at least one.—Dr. J. A. DELMEGE read a paper on Malaria Prevention, based on experience with the army in Salonika.

There was a discussion on Public Health Considerations relating to Influenza, Pneumonia, and Allied Epidemics, opened by Dr. F. G. CROOKSHANK, who urged the importance of clear thinking as to the causes of epidemics and the pursuit of historical and epidemiological methods of inquiry. A pandemic of influenza was a coördinated series of happenings, in which individuals and particular sets of circumstances play their part, but ultimately caused by forces, telluric or cosmic, involving periodic variation in the condition of all forms of life.—Dr. W. H. WYNN followed with statistics of the results of the use of vaccines for prophylaxis and treatment. He urged the importance of immediate treatment, and that pneumonia and influenzal broncho-pneumonia should be regarded as emergencies comparable to acute appendicitis or perforated ulcer, demanding immediate action. Of cases of influenzal broncho-pneumonia injected within 24 hours of the onset there were no deaths, and 71 per cent. had a normal temperature within 24 hours of the injection; whereas of those injected on the fourth and fifth day only 30 to 35 per cent. had a normal temperature in 24 hours after an injection.—The papers were discussed by Dr. A. T. NANKIVELL, Dr. J. B. FERGUSON, and others.

In the *Section of Hygiene of Maternity and Child Welfare* the Stillbirth Problem was discussed from the public health point of view by Dr. JOHNSTONE JERVIS (Leeds), and Mr. BECKWITH WHITEHOUSE (Birmingham) spoke on the causes and methods of prevention. Of constitutional causes, venereal diseases and alcoholism were the most potent, and of obstetrical causes, placenta prævia, obstructed labour, and eclampsia occupied the chief place. He advocated Cæsarean section for placenta prævia in substitution for version.

Infant Welfare Work, the Milk-supply, Sex Hygiene, the After-Care of Consumptives, Domestic Animals as a Factor in the Spread of Disease, and the Methods of Rat Suppression were among the prominent subjects discussed at other sections.

On Tuesday evening Sir FREDERICK MOTT gave an address to the Congress on Body and Mind, in which he discussed the nature of functional nerve conditions and their treatment; on Thursday evening Dr. ANDREW BALFOUR delivered the popular lecture on Links with the Tropics, mainly dealing with malaria.

Conferences of Representatives of Sanitary Authorities, Medical Officers of Health, Engineers and Surveyors to County and Sanitary Authorities, Veterinary Inspectors, Sanitary Inspectors, Health Visitors, and Rat Officers also took place. During the whole week an exhibition of apparatus and appliances relating to health and of domestic use, opened on Monday by the Lord Mayor, was held in the Bingley Hall.

We reserve for more detailed notice three papers of particular medical interest read in the sections.

(To be continued.)

THE LANCET.

LONDON: SATURDAY, JULY 31, 1920.

The Accuracy of the Medical Register.

IT cannot be too often said, or too strongly insisted upon, that the accuracy of the Medical Register is a professional necessity. The Registrar of the General Medical Council has pointed out this in our columns and in those of the *British Medical Journal* on many occasions, and we have insisted as frequently to our readers that the remedy for omissions or errors in the Register lies in their own hands. The statutory duty of the General Registrar or of the Branch Registrars ceases when an inquiry has been sent to the last registered address of the practitioner whose existing whereabouts it is decided to ascertain, and if no answer is received to such inquiry the name may be legally removed from the Register. This is done reluctantly in a certain proportion of cases, and may result in serious inconvenience to the practitioners concerned. As a matter of fact, this summary, and, be it remembered, legal course, has never been taken without provocation, and the officers of the General Medical Council employ every means, as far as time and circumstances permit, to get into communication with practitioners whose addresses have been found to be incorrect in the Register. An example, alike of the work of supererogation done by the Registrars and of the carelessness of practitioners in the matter, was furnished by what happened at the election of Direct Representatives last November. On this occasion a very large number of voting papers was returned to the Council through the Dead Letter Office. Two-thirds of these practitioners have since been traced, and their correct description will be found in the forthcoming Register, but there is still a number whose addresses cannot be ascertained, and this residual third bulks into the lengthy list which has been furnished to us by the General Registrar, and which is published on pages 259 to 263 of this issue of THE LANCET.

We are asked to request earnestly that any medical practitioners who find their names in this list will immediately communicate with the particular officer concerned in putting the matter right—namely, the Registrar of the Branch at which they were originally registered—while information from friends of deceased persons or others will be welcomed by the same officers. In publishing this list to obtain information the General Medical Council is taking a measure which cannot often be repeated, and we trust that its efforts will be rendered successful by the prompt coöperation of our readers. The reason why so many voting papers at the recent election for Direct Representatives did not reach their destination—in other words, the reason why the existing Medical Register shows a serious percentage of inaccuracy—requires no explanation. Hundreds, nay thousands, of practitioners left their homes

at short notice during the war, and as those who read the constant series of obituary notices published in this journal know only too well, a sinister proportion of them never returned. And of those who returned many have not taken up the professional careers which they had quitted, but have changed their addresses, and in some instances their branches of practice. It was only to be expected, therefore, that at the close of the war the Medical Register should require drastic overhauling and heavy correction, and to enable these things to be done the Council is making a special appeal for the help to which the officers have a right; while if this help is withheld the consequences will recoil upon the practitioners of medicine directly, while public business may be impeded.

The following points should be remembered. It is by no means unusual for doctors to practise under names which differ in some particular from those appearing on the Register in accordance with the original enrolment. Sometimes Christian names or initials are dropped or added, sometimes hyphenated names are used. It is now the custom for the Ministry of Health and other public officials to consult the Register regularly, and to decline to recognise anyone by a name which is not that registered. Therefore those who have made an alteration in name should take the necessary steps to have the matter put in order by causing a corresponding alteration to be made in the books of all the bodies whose qualifications they hold, and by notifying the fact to the Registrar concerned. The General Medical Council charges a nominal fee of 6s. for making the change, which involves some expense to it, and the fee includes the Government stamp for 1s. for a certified extract from the Register as corrected.

Cancer Research To-day.

THE discussion on cancer at the recent meeting of the British Medical Association and the annual report of the Imperial Cancer Relief Fund give an idea in what directions, after a break of five years, the attack on this problem is going to be resumed and how far it had progressed when it was interrupted by the war. A modern feature of experimental cancer research is the absence of speculation on the nature of cancer. The speculations, which were formerly a favourite pastime of the morbid anatomist, appear to have little attraction for the experimental worker in cancer. He is a sober-minded person who is out for facts which can be ascertained and established experimentally, and he has little use for speculations, brilliant though they may be, which in the present state of our knowledge must necessarily be based on insufficient grounds. A striking result of such research has been to reveal the inadequate nature of the purely morphological criteria on which hitherto the definition of malignancy has rested. Thus the fowl tumours discovered by ROUS, and transmissible by a virus, are morphologically indistinguishable from sarcomata which cannot thus be transmitted. Again, by continued irritation of susceptible cells it is possible to produce a lesion which microscopically is indistinguishable from a typical epithelioma. Nevertheless, when the irritation is discontinued the lesion may regress and heal. There are, further, certain types of tumours occurring in mice which do not grow when transplanted

back into the animal in which they originated (autoplastic transplantation), while other types of tumours always grow under these conditions. It is evident, therefore, that the term cancer, as used hitherto, has comprised types of cell proliferation which are biologically different, though morphologically similar. These different types must now be separated and distinguished by new criteria. Dr. J. A. MURRAY points out, in the annual report of the Imperial Cancer Research Fund, that auto-transplantation may prove to be an experimental test of malignancy which will render possible a differentiation of the various biological types of neoplastic cell proliferation. This trend of modern cancer research has been clearly recognised by EWING, who writes as follows in the historical introduction to his excellent book on neoplastic diseases. "The twentieth century opens as the experimental era with a systematic study of tumours throughout the animal kingdom, and it seems likely to become noteworthy as a period of specific etiological investigation which promises to widely separate many neoplastic diseases formerly held to be closely related. It may thereby prove to be the era of successful therapeutics and prophylaxis."

Biochemical investigation reveals the same difficulty in finding a property characteristic of malignancy. Not long ago many believed that cancer cells secreted toxins or ferments which destroyed the surrounding normal tissues of the host and thus enabled the cancer cells to prey on their host, who slowly became cachectic. We know now that the production of such substances is not a fundamental property of cancer cells. Their occurrence is due merely to accidental factors, such as necrosis or infection of the badly vascularised tumour. Investigations on the metabolism of cancer cells, their nutritive requirements, their chemical composition, their respiration, have so far failed to reveal any features in which the malignant cell is essentially different from a normal or a non-malignant cell. Cancer cells do not grow by preying on the surrounding tissues, and so far nothing has been found to show that the mechanism of their growth is in any way different from that of a normal cell. The results of homo-transplantation and auto-transplantation, the possibility of inducing resistance against the implantation of a cancer cell derived from a different animal, the failure to do so when the cancer cell is re-implanted into the animal in which it originated, and the biochemical investigations just referred to, all emphasise the fact that there is an essential similarity between the cancer cell and the normal cell. In many respects the likeness between the cancer cell and the normal cell of the animal in which it originated is greater than that between the normal cells of two different animals. The change which takes place when a normal cell becomes malignant is evidently a subtle one, and cannot be expressed in the comparatively crude terms of ferments, toxins, differences in amino-acids, increased affinities for food-stuffs, and so on. The nature of this subtle change cannot yet be stated; and the disability arises from the fact that our knowledge of the physiology of the normal cell life is as yet imperfect, while the phenomena of growth in the normal cell forms almost a *terra incognita*. What are the changes taking place in the cells of the skin when an abrasion induces their proliferation? And by what mechanism is their proliferation slowed and finally arrested when the normal structure of the

skin has been reproduced? These questions cannot yet be answered. But they will have to be answered before we can hope to understand how the malignant cells begin to proliferate and how they escape the control which keeps in check the proliferation of the normal cell. The cancer problem, viewed from this aspect, is a biological problem. The transplantable animal tumours exhibit the phenomenon of growth in a particularly pure and striking manner and their study has already thrown light on the problem of the growth of the normal cell. They also exhibit the phenomenon of senescence. It is here, perhaps, that cancer, which has so far defied all therapeutic attacks, is vulnerable. There are well-authenticated cases where in the human subject new growths of an undoubtedly malignant nature have undergone spontaneous absorption. This process occurs more frequently in transplanted tumours, and it has been found that it takes place during this period of senescence.

The first step in therapy is therefore indicated unless some default in the arguments can be found. It is, namely, to study the factors which determine the onset of senescence and to induce the condition experimentally. A beginning in this direction has already been made; the condition of senescence is associated with a diminished water content of the cells, and appears to be due to a diminished degree of imbibition of the protoplasmic colloids. Such a condition can be induced *in vitro* by treating the isolated cancer cells with a solution of calcium salts. But attempts to influence in this manner the tumour cells when growing in the animal have so far failed. Here a new difficulty is met with which may for long prove to be a stumbling block to therapeutic attempts. The tumours are generally badly vascularised and extensively necrosed. When substances intended to act on the tumour cells are injected into the host, the sluggish and imperfect circulation prevents them from being carried into the tumour in sufficient concentration before the host has dealt with them by excretion or otherwise. Thus even our first step must be a halting one, while cancer still guards its mystery. There was a time when it was confidently believed that we were almost in sight of the longed for solution, and that one lucky observation might remove the veil that hides it and make us the master of the disease. But we are no longer likely to under-estimate the difficulties which lie ahead while we accept the view that those difficulties are coincident with the most intricate problems of cell life.

From the Cradle to the Grave.

It has been the dream of the hygienist, the statistician, and the eugenic reformer to possess a complete record of the health of each member of the community from the day of the birth until the final demission, whether from old age, accident, or preventable disease. For a long time past the health record of the school child has been precisely recorded, and in some districts, at least, is continuous with the data obtained from infant welfare and maternity centres. An opportunity for accumulating such information upwards seemed to be afforded by the medical benefit regulations under the National Insurance Act of 1911, which required the panel practitioner to keep records of

the diseases of patients and of his treatment of them. But the form of record then drawn up with the help of the British Medical Association soon proved unsatisfactory, the cards containing particulars of illness being sent year by year to the Insurance Commissioners, who found it impossible to bring together the particulars of illness in regard to a particular patient for successive years, although they had deprived the practitioner of the chance of doing so without undue clerical labour. The system, indeed, seemed to the busy clinician to afford the maximum amount of annoyance with the minimum return of value to himself or anyone else, and it was with a sense of intense relief all round that the duty of keeping any record at all was remitted under the pressure of war. When this pressure relaxed the obligation was not immediately reimposed, for the reason that it was thought better to take the opportunity of devising something more proper to its purpose than the old record had proved to be.

In the spring of this year it will be remembered that a committee was appointed jointly by the Minister of Health and the President of the Scottish Board of Health to consider and advise them as to the new form of this health record. The personnel of this committee, including as it did distinguished representatives of all affected departments of State and medicine, under the chairmanship of Sir HUMPHRY ROLLESTON with two medical members of the Ministry of Health as secretaries, was a sufficient guarantee for the thoroughness of the inquiry, and their report now issued as a white paper¹ considers, in a way in which they have never been considered before, the rival claims arising out of the desire for statistical information and of the ability of the hard-worked practitioner to supply this information. The committee has agreed that the form of record must now be framed so as to afford a continuous story of the insured person's illnesses, and that it shall remain in the hands of the insurance practitioner who is responsible for the insured person's care. Granted these obviously reasonable conditions, it remains to be seen what kind of records it is fair to demand of the doctor. He will no longer have in any case the useless trouble of copying details from card to card at the end of the year; his time will also be further saved by the entry on the patient's card in the first instance of certain particulars by the Insurance Committee. Retaining the card himself, it will be possible for him to use it as his own index register of insured persons. The committee would now impose on the practitioner nothing more than the obligation of making such a clinical record as will be of value to himself and to any other practitioner attending the patient later. Some valuable paragraphs in the report deal with the question of provisional diagnosis, which is the special point too of an appendix drawn up by Sir JAMES MACKENZIE and the staff of the St. Andrews Institute for Clinical Research. Stress is here laid once more on the defects of medical knowledge in the early stages of disease, and the danger of recording as a diagnosis conclusions concerning the nature and causes of illnesses which cannot be regarded as scientifically ascertained. In the new record card, recommended by the committee, separate columns are provided for symptoms, treatment, and provisional diagnosis on the one hand, and on the other for diagnoses of which the practitioner feels reasonably certain.

Having thus determined on broad lines the scope and extent of the clinical records, the report proceeds to discuss the administrative and statistical uses which can be made of them. The mere maintenance by the practitioner of a continuous record of medical histories will in itself make it possible for departmental inquiry into, say, sickness at a particular age or falling upon those engaged in a specified occupation. The difficulty lies in the fact that the records on the accepted plan will not be returned to the central department until the patients have died or gone out of benefit. Three alternative ways, none of them free from objection, are considered for obtaining the necessary general conspectus, and in the choice between these the committee were not unanimous, while recognising that systematic tabulation of selected portions of the records of a large and clearly defined class of persons would be likely to yield results of value. A promising suggestion, which the committee held to be outside its terms of reference, was to use the certificates of incapacity sent in to the Approved Societies as the basis of some useful analysis without involving the collection of clinical material in the hands of practitioners. It is clear the committee has achieved much by free discussion. But whilst signing the report as a whole, Dr. J. BROWNLEE tabled his preference that records of certificated disability should be kept separate from the clinical notes so as to be transmitted to a central department at suitable intervals. This may still be found practicable. The immediate necessity is to obtain the willing and whole-hearted co-operation of the clinician himself, without which the statistical pyramid has no base, and this is assured by the whole tone of the recommendations. It is hoped that the new system of records may come into force on Oct. 1st next.

Patent Medicines.

THE Proprietary Medicines Bill was published this week. In general its provisions confirm the recommendations contained in the report of the Select Committee on Patent Medicines ordered by the House of Commons to be printed August 4th, 1914. This Committee, during the three sessions of Parliament over which its labours extended, held 33 public sittings and examined 42 witnesses, of whom more than 14,000 questions were asked. There was thus an accumulation of evidence gained on all questions of the sale of patent and proprietary medicines and medical preparations and appliances, and of advertisements relating thereto. The situation is summarised as follows. For all practical purposes British law is powerless to prevent any person from procuring any drug, or making any mixture, whether potent or without any therapeutical activity whatever so long as it does not contain a scheduled poison. Nor can the law prevent any person from advertising such mixture in any decent terms as a cure for any disease or ailment; from recommending it by bogus testimonials and the invented opinions and facsimile signatures of fictitious physicians; or from selling it under any name he chooses, on the payment of a small stamp duty, for any price he can persuade a credulous public to pay. The Bill aims at putting an end to these abuses, and its progress in Parliament will be watched with the greatest interest. We shall have occasion to deal with the provisions more fully in future issues.

Annotations.

"Ne quid nimis."

A STANDARD ARTIFICIAL LEG.

ARTIFICIAL limb-making has proved a more difficult task than was at one time supposed. The delay in obtaining exactly the appropriate arm or leg to replace the one which has been lost in the service of the country has given rise to annoyance on the part of the patient and caused anxiety to his medical adviser, who knows that the sooner the appliance becomes part of his everyday wear the better for the pensioner in mind, body, and estate. It is satisfactory to learn that arrangements to this end are now well forward at the Ministry of Pensions, which has been considering for three years the standardisation of the types of artificial legs, the object being to facilitate repair and replacement. Work on standardisation was carried out last summer by a committee under the chairmanship of Sir Reginald Bacon, and has since been completed by the Minister's advisers, Sir Charles Kenderdine, director of artificial limb supplies; Mr. T. H. Openshaw; Mr. E. Muirhead Little; Mr. R. C. Elmslie; Mr. Michael Longridge, past president of the Institution of Mechanical Engineers; and Mr. A. D. Bailey, technical adviser to the Ministry. The specification of these standard limbs has been approved by the Advisory Council to the Ministry and by Sir Lisle Webb, Director-General of Medical Services. In a few months all artificial legs of wood or leather supplied to pensioners will comply with the new specification. The method adopted has been to standardise the mechanism of the limb and the metal component parts, leaving the actual limb to be fitted to and assembled for the individual pensioner by the limb-maker. The latter point is of great importance, as every limb must necessarily be adapted to the individual needs of the man. The principle of the artificial leg is that from the ankle up to the thigh a universal pattern will be capable of being supplied in quantity, and that for each man, whether he needs a right or a left leg, all that remains is to affix a suitable foot and a suitable bucket. These two latter items, of course, prevent any attempt at standardisation and mass production of whole limbs. The bucket, for instance, must in each case be made to fit accurately, and a modern ankle-joint will be so constructed as to give the amount of play acceptable to the wearer.

Standardisation is not to be allowed to interfere with progress. It is a standardisation of those types of limbs which have been thoroughly and extensively tested, and of which about 35,000 have been issued. Further improvements will be made, and the types will be modified as these are tested and proved. The Ministry have had in hand the problem of providing a lighter artificial leg, made of duralumin or some similar metal instead of wood and leather, and one type of this light limb has now received the approval of the advisers. Light limbs have evident advantages for certain cases. The pattern now approved will, it is hoped, be capable of being made on a large scale by an engineering firm in such a way that only the actual fitting to the man need be carried out by a skilled limb-fitter.

ANGEITIS IN WILD ANIMALS.

Dr. Herbert Fox,¹ Director of the Laboratory of Comparative Pathology of the Philadelphia Zoological Garden, describes the incidence of angeitis, a collective term including productive endarteritis and degenerative arteritis or arterio-sclerosis, in 5464 autopsies on wild animals. Only 86 cases, or 1.5 per cent., were discovered, their distribution being as follows: mammals autopsied, 1806, angeitis, 33 cases, or 1.8 per cent.; birds autopsied, 3571, angeitis, 53 cases, or 1.4 per cent.; all other animals autopsied 87, angeitis, 0. Degenerative arteritis

was observed in 31 mammals, the orders Primates, Carnivora, Marsupialia, and Ungulata being represented. The lesions appeared in the form of roughened, rather opaque areas in the intima, with degeneration of the media, but the sharply outlined, heaped-up, ulcerating roughened intima, so characteristic of human arterio-sclerosis and present to a slight extent in the Aves, was missing. The aorta was by far the most frequently affected vessel, the lesions being usually found at the top of the arch and in the thoracic portion. Deformity was never great, and aneurysms were found only four times. Ten of the 31 cases showed frank renal lesions, about equally divided between the degenerative and glomerular types. Fifty-one instances of degenerative arteritis were found among the class Aves, the condition being commonest in birds of prey, parrots, and gallinaceous and aquatic birds. In birds of prey the lesions, while most pronounced in the aorta, were found also in the main branches in the form of heaped-up, irregular, yellowish-grey intimal patches over the degenerated media. In parrots the lesions were common in the smaller vessels and strongly resembled senile arterio-sclerosis, with its medial degeneration and calcification as seen in man. The gallinaceous and aquatic birds showed insular atheroma in sharply defined areas. Chronic renal lesions were found in 17 of the 51 birds, the degenerative type being apparently the most frequent. Productive endarteritis was present in two mammals—a rodent and an elephant—and two birds. In the birds and the rodent the process was associated with chronic intestinal lesions, and in the elephant with chronic pulmonary tuberculosis. In only two of the whole 86 cases was chronic valvulitis noted, the aortic and mitral valve being involved. In conclusion, Dr. Fox states that arterio-sclerosis was very common in the orders showing the greatest number of cases of gastro-enteritis, this being specially true of parrots, aquatic birds, and herbivorous and carnivorous mammals. The animals most affected were those prepared by nature for severe or prolonged effort, such as in flight or fight.

WAR LOSSES OF THE ITALIAN NAVY.

THE Italian Navy, we are told by the well-known Colonel (Surgeon-Captain) C. M. Belli, in the *Annali di Medicina Navale*, lost 3925 officers and men killed by accidents or enemy action during the war. Italy joined us in May, 1915, and in the five years 1915-1919 the average annual strength of her navy was 3146 officers and 85,780 men, of whom 172 officers and 3753 men were drowned or killed, or, per thousand annually, 10.7 officers, 8.7 men. It is noted that the Italian Army also lost a higher proportion of officers than of men. In all, 150 were killed in the air or from the air (bombs, &c.), 362 in action, 980 in explosions or other accidents on board, and 2433 were drowned. As for deaths from disease, the numbers have not yet been made out for officers, but amongst the men there were 2543, being 68 per cent. of the deaths by enemy action or violence. Influenza claimed 1241; it defeated all efforts at prevention. Tuberculosis took another 195. Its incidence increased yearly from 0.1 per 1000 in 1915 to 0.7 per 1000 in 1919. Its chief mortality fell not upon the small craft, destroyers, and so on, which went to sea, and whose complements were specially selected from men of good physique, but on the battleships, which did not go to sea, but were used as depôts. They had ship's companies more numerous than in peace time, and amongst them were many men, formerly invalided, but now called up, who speedily broke down and infected their neighbours before their condition was recognised. Cerebro-spinal fever caused 68 deaths. Malaria, with 64 deaths, showed only a small increase on normal times, though many men were employed ashore in unhealthy localities. This fortunate result is ascribed to prophylactic measures, and especially to "quininisation" (method not stated). Antityphoid inoculation was introduced in February, 1915. Its effect was at once noticeable. Only 46 deaths from typhoid and 9 from paratyphoid are reported in the five years of the war; 27 men died of ictero-hæmorrhagic spirochaetosis or

¹ The American Journal of Medical Sciences, June, 1920.

epidemic jaundice. There were only 4 deaths from cholera, though three Italian ships, carrying Austrian prisoners (captured by the Serbs), had 1500 deaths on board during a three days' passage. Each Austrian bore a label stating his various vaccinations and inoculations, and it appears that the Austrians contracted cholera because they had not been vaccinated within 12 months, but the Italians on board all escaped, for they were revaccinated every three months. Amoebic dysentery caused only 6 deaths; they are ascribed to infection brought to Taranto by the English. No deaths from bacillary dysentery occurred. The splendid cleanliness of the Italian detachments sufficiently explains why there were no cases of typhus or relapsing fever among their detachments ashore in Albania. Altogether the record is a good one.

TUMOURS OF THE CAROTID BODY.

OF the carotid body little is known. Its origin, whether from endoderm, mesoderm, or ectoderm, is doubtful. It seems to belong to the chromaffine system and to have a relation to the sympathetic nervous system like that of the medulla of the suprarenal body. Its tumours come under clinical observation, but the number of recorded cases, of which some are doubtful, does not exceed 80. The most common tumour is adenoma. In the Bulletin of the Johns Hopkins Hospital for June Dr. M. R. Reid has reported three cases from Professor Halsted's clinic. The following is an example:—

A man, aged 46 years, was admitted on March 28th, 1913. In February, 1908, he accidentally discovered a small lump about midway between the angle of the jaw and the clavicle. It caused only disfigurement and gradually enlarged "in spite of all sorts of treatment." Pulsation was first observed in 1911, and had become much more pronounced in the last two years. He was told he had an aneurysm, and advised to see Dr. Halsted. On admission this diagnosis was confirmed by the many surgeons who examined him. A large expansile pulsating mass involved the left side of the neck from the lobe of the ear to within 3 cm. of the clavicle and from the middle of the neck anteriorly to the trapezius posteriorly. Its external circumference was 17 cm. The trachea was displaced 1 cm. to the right of the middle line. A thrill was felt along the posterior part of the tumour, which was slightly compressible. Firm pressure below the tumour did not lessen the pulsation in it. There was a scarlatiniform rash over the upper chest and neck. The left wall of the pharynx was dislocated towards the median line, so that the tonsil lay in the median line below the uvula. The entire pharynx pulsated visibly. Dr. Halsted tied the common carotid artery, which occupied an abnormally lateral position and was surrounded by dilated venules. The artery was dilated and very soft. After the operation the tumour did not pulsate, was much softer, and 5 cm. smaller. A faint bruit, however, was audible. On April 10th, 1919, the patient returned because the pulsation had recurred and the tumour had gradually enlarged. A huge swelling involved the left side of the neck from the mastoid process to the middle line and downward nearly to the clavicle. The trachea was displaced 2 cm. to the right. Over the tumour the skin was erythematous, and over the lower part were large tortuous veins, suggesting angioma. Slight heaving pulsation was visible and a thrill was felt. There was a continuous, almost musical, bruit, with systolic accentuation. Firm pressure over the left common carotid did not affect the pulsation of the supposed aneurysm. There was no bulging of the left side of the pharynx and the tonsils were in normal positions. There was complete paralysis of the left vocal cord. Dr. Reid suspected an angiomatous tumour or an arterio-venous fistula. He performed a difficult operation requiring 4 hours and 20 minutes. Huge vessels were encountered everywhere. The carotid artery was not recognised. It was necessary to resect the vagus nerve and internal jugular vein and the eleventh and twelfth nerves, which ran through the tumour, had to be divided. The sterno-mastoid muscle was excised with the tumour. For 36 hours oedema of the epiglottis caused dyspnoea and then convalescence proceeded. The specimen was very vascular, weighed 190 g., was yellowish-brown on section, and proved to be an angioma of the carotid body.

Keen, who was the first American to write at length about tumours of the carotid body, has given the best illustrations and descriptions of their pathology. He speaks of 12 points which may help in diagnosis: (1) the position at the bifurcation of the carotid artery;

(2) movability laterally but not vertically; (3) ovoid in shape; (4) smooth and not lobulated; (5) single; (6) transmitted pulsation; (7) bruit and thrill; (8) bulging of the wall of the pharynx; (9) pupils occasionally constricted; (10) slow growth; (11) long duration; and (12) a rather firm elastic consistency. Speaking negatively, he says they are: (1) not tender; (2) not painful; and (3) the deformity is the main complaint. Yet these tumours have seldom been correctly diagnosed before operation. Aneurysm, as in the case narrated above, has often been diagnosed. Nothing is known of the function of the carotid body, nor have any functional disturbances been described in connexion with its hyperplasia. But in the present case the patient's skin was of a yellowish dark colour and in another of Dr. Reid's cases of a light lemon colour. The pigmentation in both cases cleared up after removal of the adenoma. Were the body juices saturated with chromaffine substance? The pigmentation was certainly associated with the hyperplasia of the gland. As to the treatment, the results are not satisfactory. A mortality of 30 per cent. and a morbidity nearly as high should make the surgeon hesitate before operating. Most of the patients have been operated on for cosmetic reasons and would not have submitted had they known that it is usually necessary to divide the carotid artery, jugular vein, vagus, and hypoglossal nerves. Pneumonia, hæmorrhage, cerebral anæmia, are given as causes of death in this order of importance. Keen and other eminent surgeons are opposed to operation when the tumour is large and the important structures mentioned have to be sacrificed. Small tumours which can be freed from them should be removed. The long duration of the growths reported (1 to 40 years) seems to indicate that a carotid adenoma is not prone to become malignant. For malignant tumours necessarily a radical operation is indicated.

ATROPHY DEPENDENT ON AND CONDITIONED BY HYPERTROPHY.

AMONGST gland cells, perhaps the most inexplicable so far as its multifarious uses and complexity yet separability of functions are concerned is the liver cell, an apparently simple histological unit as revealed by the microscope, yet how obscure is its metabolism and its range of influence upon the adjoining cells of a liver lobule. One feature of its potential activities stands out very markedly. Ponfick and others by means of experiments on rabbits showed many years ago that if a quarter or a half or more of the liver be removed the original bulk and the activities of the organ are renewed within a relatively short time. Rous and Larimore, of the Rockefeller Institute, have recently made other observations in the same direction, which materially add to our knowledge of the relation of the portal blood to liver maintenance. They find that occlusion of portal branches to a portion of the rabbits' liver leads to a progressive, and ultimately complete, atrophy of the parenchyma in the region deprived of portal blood and to hypertrophy of the hepatic tissue elsewhere, which receives such excess of blood. Three-fourths of the liver may thus be reduced to a fibrous bag within two months, while the remaining fourth attains the bulk of the entire original organ. The atrophy is simple, unaccompanied by obvious degenerative changes or by the least connective tissue replacement. More important, however, it is conditional in nature, failing to progress when the bile-duct from the proliferating liver tissue is ligated and hypertrophy checked in this way. Similar changes occur in the dog, but more slowly. The bile secreted by the part of the liver far advanced in atrophy is almost colourless and may give but a feeble Pettenkofer reaction, though the glycogen in the atrophic cells is about the same in amount and distribution as in the hypertrophic parenchyma. Here we have local atrophy dependent upon a local hypertrophy of the same organ, a condition which contrasts with that form of local hypertrophy well known to pathologists dependent upon destruction, leading to compensatory hypertrophy.

ALCOHOL IN NORWAY AND SWEDEN.

ACCORDING to the *Economic Review* (July 23rd, 1920) steps are being proposed in Norway to introduce a new control over the importation of alcohol in that country. The following paragraph taken from the above journal is of interest in this connexion:—

Norway's import of alcohol.—A Bill has been submitted to the Storting in connexion with commercial and maritime agreements between Norway and France, Portugal and Spain relating to the import of alcohol. It contains the following clauses: 1. Perpetual prohibition of the import of spirits and intoxicants, except for medicinal, technical, and scientific use. 2. Permission to import light wines. 3. Future agreements shall not prevent the import of light wines and alcohol for medical and scientific use from constituting a monopoly with a view to guaranteeing social and fiscal interests. (*Sjöfartstidende*, June 12th.)

In the same number there is another item of news on this question referring to the production of alcohol from wood in Sweden.

The output in Sweden.—At the beginning of 1920 15 sulphite spirit factories, with a yearly output capacity of 10 mill. kg. of 95 per cent. spirit, were working in Sweden. Another 7 factories with a total capacity of 7 mill. kg. a year will be established during 1920. These 12 mill. kg. or 21 mill. lit. of spirit correspond to the calorific power contained in 9500 t. of benzine. (*J. Econ. Européen*, June 12th.)

It would thus appear that the question of alcohol as a power agent is being seriously handled by the Swedish Government. The countries which possess ample sources of water power promise to get the lead in industrial developments, based, amongst other things, on synthetic issues. The question of the possibilities of utilising our own natural power resources at home and in our vast colonial empire is no doubt receiving the careful attention of our engineers and chemists, whose energies in these matters are called for unless we choose to be left behind in the race.

ARTERIO-SCLEROSIS OF THE EYE.

THE ophthalmoscopic signs which point to high general blood pressure or to arterio-sclerosis are common ground to the ophthalmic surgeon and the physician. Clifford Allbutt, Osler, and others have thrown light on the conditions which cause the increased blood pressure. Ophthalmic surgeons, beginning with Marcus Gunn, have studied the ophthalmoscopic signs of it; in recent years P. C. Bardsley and Foster Moore have amplified his observations. In the *British Journal of Ophthalmology* for July this subject is reviewed by P. H. Adams. Ophthalmic surgeons, as he says, see an enormous number of patients between the ages of 40 and 55 for the purpose of ordering presbyopic glasses, and serious responsibility is theirs if, when the symptoms are suspicious, they are content to order a pair of reading glasses without going further into the case. What, then, are the ophthalmoscopic signs which ought to receive special attention? (1) The width and brightness of the central white reflex from the arteries, a decidedly narrow and bright reflex constituting what is generally known as the silver wire appearance, but which Bardsley prefers to call copper wire—it is indicative of very high tension; (2) the indentation or obliteration of the veins where they are crossed by the arteries, showing hardness and loss of transparency in the latter; and (3) kinking of the veins at the crossings. These are early signs, and may be considerably modified by measures directed to diminishing the blood pressure or eliminating the toxic cause of it. Signs of more confirmed disease are actual irregularities in the course of the retinal vessels—what is called beading is sometimes seen—patches of oedema, hæmorrhages, or patches of exudation. Such signs do not necessarily prove that serious intracranial disease is impending, but they decidedly point that way, even in the absence of albumin in the urine. This is shown by some statistics published by Foster Moore.¹ The eye, it has been well said, is the window of the brain. According to Adams, the older the patient with arterio-

sclerotic changes the better the prognosis with regard to life, irrespective of the presence of albumin in the urine to a large extent, whilst the younger the patient the worse the prognosis, and especially so if albumin is present in the urine. With regard to the prognosis qua vision, except when the whole of the retinal circulation is stopped, as in thrombosis of the central vein, this depends chiefly on the extent to which the macular region is affected. In cases—and they are quite common—where gross signs of arterio-sclerosis are present but the macula remains free, excellent vision may remain. It is a remarkable fact that there is no constant relation between an excessive systemic blood pressure and a raised intra-ocular tension. Whatever the underlying causes of glaucoma may be, a general increase in the arterial blood pressure is not an essential part of the disease.

THE FEDERATION OF MEDICAL AND ALLIED SOCIETIES.

THE first annual general meeting of this Federation was held on Tuesday last, when a Report was presented and unanimously adopted, reciting the activities of the Federation during its inaugural year of work. Sir Malcolm Morris, the chairman of the Executive Council of the Federation, who presided, pointed out that for the medical profession to speak with a corporate voice and in sympathy with public aims was a necessity of the times, and every constituent element in such a union must gain in strength from mutual support. From the Report of the Federation and from the words of the chairman of the Executive Council, we learn that it is entirely outside the policy as well as contrary to the desire of the Federation to rival or supersede any of the existing organisations, great and small, which have done so much work along general and special lines for the advancement of medicine. The hope is to increase the efficiency of all such activities by providing a round table at which matters concerning the public health of the nation can be discussed, so that a policy may emerge, founded on high ideals of preventive therapeutics, expressing the mean of professional opinion and reconciling these views with national developments. The object is profoundly important, and the chances of accomplishment will be high if general and professional support is forthcoming promptly.

THE house and library of the Royal Society of Medicine will be closed during the whole of August for repairs and cleaning.

WAR-TIME VOLUNTARY HOSPITALS.—Of the innumerable forms of voluntary and generous service rendered to the nation during the war none was more valuable, and few were more unobtrusive, than the establishment and maintenance of private houses and other buildings as hospitals for the sick and wounded. During the four years of the nation's emergency 3244 such hospitals were open for the treatment of officers and men of the army, their distribution in areas being as follows: Aldershot Command, 40; Eastern Command, 687; Irish Command, 105; London District, 352; Northern Command, 439; Scottish Command, 314; Southern Command, 660; Western Command, 637; Guernsey and Alderney District, 6; Jersey Command, 4. The work of the hospitals having now been practically completed, the Army Council, in name of the nation, have placed on record their thanks to those whose generosity made the work possible, and the Council are also issuing an inscribed scroll which may be hung in each building as a permanent memorial of the patriotic purpose to which it was devoted in 1914-19. The inscription is as follows:—

"During the Great War of 1914-1919 this building was established and maintained as a Hospital for British sick and wounded. The Army Council in the name of the nation thank those who have rendered to it this valuable and patriotic assistance in the hour of its emergency, and they desire also to express their deep appreciation of the wholehearted attention which the staff of this hospital gave to the patients who were under their care. The war has once again called upon the devotion and self-sacrifice of British men and women, and the nation will remember with pride and gratitude their willing and inestimable service."

More than 500 scrolls have already been issued, and the remainder will be despatched promptly.

¹ Quarterly Journal of Medicine, January, 1917.

THE MEDICAL REGISTER. UNTRACEABLE PRACTITIONERS.

WE are requested by the Registrar of the General Medical Council to give publicity to the following lists of medical practitioners whose present addresses are unknown. We deal more fully with the subject on page 253 of this issue. Anyone who finds his or her name included should communicate immediately with the Registrar of the Branch whose address is given at the head of the particular list in which the name occurs:—

I. (a)—PRACTITIONERS REGISTERED ON THE ENGLISH LIST.

Communications in regard to this list should be sent to the Registrar of the General Medical Council, 44, Hallam-street, Portland-place, London, W. 1.

President of the International Committee: and by Dr. MAYER, the secretary-general, who gave an account of the affairs of the society since its last meeting in the United States in 1914. Professor KEEN, the President, then delivered an inaugural speech "on some of the ideas which, as doctors, we ought to defend." He dealt with the education of a doctor, scientific research, professional conscience, venereal disease, the altruism of the medical profession, and the value of total abstinence. Lastly, he spoke of the courage shown by doctors not only on the battlefield but during civil epidemics. The address, delivered in English, was listened to with rapt attention by an audience which filled the large amphitheatre of the École de Médecine, and for the benefit of those whose English was not fluent Professor Keen had thoughtfully provided a French translation. The formal meeting then closed, and the serious business of the session commenced.

Scientific Proceedings and Discussion.

Surgical hæmatology.—M. DEPAGE and M. GOVAERTS communicated on the first day a report upon the results obtained by the examination of the blood in cases of anæmia due to hæmorrhage. They showed that intravenous injections of salt are useless after severe hæmorrhages; that post-hæmorrhagic anæmia does not reach its maximum until three days after the bleeding has taken place; that leucocytosis, and not a diminution of the red blood corpuscles, is the first hæmatological feature in hæmorrhage, and that when injected red blood corpuscles have been properly selected to avoid agglutination, they remain in the blood of the person who receives them for at least ten days.

Dr. E. A. GRAHAM, of New Orleans, read an interesting paper on *Asphyxia*, in which he stated that this condition may be produced by (1) interference with the intake of air; (2) interference with the power of the blood to carry oxygen or to remove carbon dioxide; (3) interference with the circulation of the blood; (4) disturbance of the power of the tissues to utilise oxygen. He pointed out that a change of pressure in one pleural cavity is associated with a similar change in that of the opposite side. Both lungs, therefore, are nearly equally compressed when their expansion is restricted by air or fluid. The commonly accepted condition of "collapse" of one lung with maintenance of respiration by the other does not occur.

Contributions were also made by M. PEUGNIEZ, of Cannes; by M. PUJOL-Y-BRULL, of Barcelona; and by M. DE QUERVAIN, of Berne, on Surgical Hæmatology; by Mr. GIBSON, of New York on Blood Analysis; and by M. REYNÈS, of Marseilles, on the Danger of Urea Retention in the Wounded and those who have undergone operations.

Surgery of the heart and blood-vessels.—Under the chairmanship of M. GIORDANO, of Venice, the second day was devoted to the surgery of the heart and great vessels. Communications on the subject were made by TUFFIER, of Paris; SENCERT, of Strasbourg; GOODMAN, of New York; ALESSANDRI, of Rome; JEANBRAU, of Montpellier; DELAGENIÈRE, of Le Mans; and SOUBBOTITCH, of Belgrade, whilst for want of time no less than 13 papers on the subject had to be taken as read. The wealth of papers showed the interest which the subject excites at present. There was consequently no opportunity for discussion, which, in view of the diversity of opinions expressed, might have proved animated. The general trend of opinion seemed to be that in skilled hands better results were obtained by the suture of wounded vessels than by their ligation, whilst the results obtained by Tuffier in the surgery of the heart were especially gratifying. He showed that in the recorded cases, which now number several hundreds, the mortality is about 50 per cent. after operation, and it is about 5 per cent. higher in stabs than in bullet wounds.

Fractures of the femur.—The interest excited in the treatment of fractures of the femur was shown by the fact that no less than 21 contributions were made to the subject, whilst Major MEURICE SINCLAIR gave an instructive demonstration of his method, partly by means of a well-arranged series of models and partly by

INTERNATIONAL SOCIETY OF SURGERY: THE PARIS CONGRESS.

(FROM A SPECIAL CORRESPONDENT.)

THE fifth congress of the International Society of Surgery was held at Paris from July 19th–23rd, under the vivacious presidency of Professor W. W. KEEN of Philadelphia, the G.O.M. of surgery in the United States, the fourth having taken place at New York in April, 1914. At a preliminary meeting held on Sunday afternoon and attended by delegates from many countries it was found necessary to raise the triennial subscription from 50 to 75 francs. It was determined that Germans, Austrians, and Turks should be excluded from membership, and the action taken by the English, French, and Belgian delegates in 1917 was thereby confirmed. Poles, Czech-Slavs, and Neo-Greeks (i.e., Smyrna and Jugo-Slavs) were readmitted, whilst a new committee representing South America was created. Very complete arrangements had been made for the work of the Society at the Faculty of Medicine by the French surgeons, whilst the committee of ladies, with the kind help of Madame Lorthioir, made the ladies' visit equally successful. In the minds of all, however, there was a feeling of personal loss in the absence of Madame Depage—drowned in the *Lusitania*—who at all previous meetings of the society had been a most charming and indefatigable hostess.

Inaugural Meeting.

Each morning of the week was devoted to visiting the hospitals and clinics, whilst on every afternoon there was a scientific meeting, which began at 2 o'clock. The inaugural meeting was held on Monday afternoon, July 19th, with an address from M. HONNORAT, the Minister of Education, who introduced the Day-light Saving Bill in France. Addresses were also delivered by M. HARTMANN, F.R.C.S. Eng., President of the National Committee for France; by M. WILLEMS,

lantern slides. The net result of the day's work is that a new standard of results has been attained, and that much more perfect results are required, both as regards the utility and appearance of the limb, than was formerly accepted. Perhaps there was a little too much dependence placed upon mechanical methods by some of the speakers as against prolonged attention to minute details.

Radiotherapy, with Sir D'ARCY POWER presiding in the absence of the President, occupied the whole of a long afternoon, and 22 papers were offered for the consideration of a large audience. M. REGAUD was especially happy in his report upon the rational basis, technical indications, and general results of radiotherapy in malignant disease. He was followed by Dr. FINZI, who considered the action of radiations on tumours, the type of growth for which radiation should be used, the type of radiation to employ, and the after-effects of treatment.

M. ABBE gave a lantern-slide demonstration of the β and γ rays, and demonstrated the effects of magnetism upon the radium emanations, whilst Dr. COOLIDGE showed an apparatus for taking X ray pictures.

Tetanus.—The last day of the session was devoted to tetanus. Professor Colonel S. L. CUMMINS, A.M.S., introduced the subject by a report on tetanus in the British Army during the European War. He drew attention to the cases of "modified" and "local" tetanus, which were unknown before the use of prophylactic injections of antitetanic serum. He advocated the use of intrathecal injections, supplemented by large doses given into the muscles and subcutaneously.

The General Meeting.

At the general meeting of the society it was determined that the official languages in which contributions might be made were English, French, Italian, and Spanish. The next meeting will be held in England in 1923 under the presidency of Sir William Macewen, C.B., Mr. Charles Ryall becoming delegate; Sir Edward H. Taylor, of Dublin, Mr. J. E. Roberts, of London, and Mr. Gerald Stanley, of Paris, being elected members of the National Committee for Great Britain and Ireland. It was further decided that the subjects for "rapports" in 1923 should be: (1) sero-therapy and vaccino-therapy (except tetanus) in surgical affections; (2) fractures of the base of the skull; (3) malignant disease of the colon; (4) arthroplasty.

The general meeting closed with a vote of thanks to the committee of ladies under the leadership of Madame Lucas-Championnière, Madame Hartmann, and Madame Walther, who had perfected the arrangements for giving pleasure to the ladies who accompanied the members of the society.

Entertainments.

In spite of the fact that things are still far from normal in Paris owing to high prices, early hours, and shortage of small change, the visitors were lavishly entertained, and as the weather was perfect the gardens were used to the best advantage. Professor W. W. Keen, the President of the Congress, gave a reception in the magnificent house of Madame la Comtesse René de Béarn in the rue Saint-Dominique, where there was excellent music; the municipality of Paris received the members of the Congress at the Hotel de Ville; MM. Auvray, Pierre Duval, Faure, Hartmann, Michon, Proust, Robineau, Tuffier, and Walther, the leading surgeon in Paris, invited a large number of members and their wives to dine *al fresco* in the beautiful grounds of the Cercle Interallié in the faubourg Saint Honoré; Mr. Gerald Stanley, F.R.C.S. Eng., gave a dinner to several of the English visitors at his house in Passy; and there was much private entertaining. The public banquet, which is always a feature of congresses and international gatherings, was held at the Palais d'Orsay, whose suite of reception rooms overlooks the Seine. It was attended by over 150 ladies and gentlemen, under the chairmanship of Professor Keen. The chairman, in a series of witty speeches, acted the part of a showman and produced "a lion" to respond to the toast of each country as it was proposed.—The society ended its very successful meeting on Friday, July 23rd, and on Saturday morning 75 members and their wives left Paris on a three days' tour to the battlefields of the North of France.

IMPERIAL CANCER RESEARCH FUND: ANNUAL MEETING.

THE eighteenth annual meeting of the Imperial Cancer Research Fund was held on July 22nd at the Examination Hall, Queen-square, London, the Duke of BEDFORD presiding. Among those present were Sir Norman Moore, Sir William Church, Sir George Makins, Sir Frederick Andrewes, Sir John Bland-Sutton, Sir Rickman Godlee, Sir John Tweedy, Dr. William Bulloch, Sir G. Sims Woodhead, Dr. B. R. G. Russell, Dr. W. Cramer, Dr. J. A. Murray (director), and Mr. F. G. Hallett (secretary).

The Fundamental Problems of Research.

Sir WILLIAM CHURCH, in moving the adoption of the report, gave a summary of the investigations during the past year, in which he stated that the director had continued the autologous grafting experiments, in which by transplanting an animal's own tumour to a part of its body away from the site of the primary growth, an artificial secondary growth is established. Dr. Murray stated his own view thus:—

"The efforts of many investigators in the period of 1900-1914, in addition to the great mass of facts elicited by the experimental study of cancer in animals, have gradually crystallised informed opinion to the conviction that the fundamental problems of cancer research involve the elucidation of processes which take place inside the parenchyma cells of malignant tumours. Much of the work falling within this period has been planned and interpreted on bacteriological lines, even by those workers who recognised the many differences between cancer and ordinary infectious diseases. The perfect reproduction of the pathological-anatomical features of spontaneous human and animal cancer by transplanted growths has too frequently been taken to warrant us in regarding the cancer cells as a virus implanted in the body to which they are so foreign that their peculiarities may be taken for granted, whereas every advance in our knowledge of them only enhances their similarity to normal cells. The essential differences must therefore be of the most subtle and delicate kind. It was felt that the gross analogy with ordinary infectious diseases underlying earlier work on the immunity to transplanted growths was not leading to positive results applicable to the disease as it occurs naturally. The mechanism of induced resistance to successful grafting is without effect against established transplanted tumours, and it has no influence on recurrence or metastasis of spontaneous cancer. This curious discrepancy, first brought out by the work of Haaland and Russell, is still unexplained. Provisionally it may be assumed that the explanation halts for want of knowledge of imperfectly understood features of cell-life the perversion of which is essential to the cancer process. Instead of elaborating still further the analysis of induced resistance it was considered desirable to break fresh ground and undertake the study of the metabolism of the cancer cell in as many ways as possible.

In the first instance it was decided to investigate the phenomena of cell respiration, normal and cancerous. The reasons for this choice were, firstly, the well-known dependence of cancer cells on close proximity to the blood-supply. The extensive necrosis in rapidly growing tumours is usually seen to affect all the cells with the exception of a narrow layer a few cells thick around the blood-vessels. Secondly, the work of J. C. Drummond had shown that the food necessities, basal and accessory, of tumours correspond so closely to the needs of the normal that it is impossible to influence the growth of cancer cells without jeopardising the life of the host. There was, therefore, not much prospect of discovering vulnerable features in the vital necessities of tumours in this direction."

Methods of Approach.

In pursuing one such investigation Dr. W. Cramer, Sir William Church continued, had examined the action of a number of inorganic substances on cancer cells. The first step in these investigations is to expose emulsions of a transplantable tumour to the reagent in the test-tube, and find out by inoculating the treated emulsion into susceptible animals the amount of damage produced. Salts of cerium were found to be the most active of those tested. Manganese and uranium salts were less potent, and the other elements experimented with were without effect in strengths which could be tolerated by the experimental animals. None of these substances, however, had any influence on growing tumours, a failure probably due to the irregularity of the circulation in the tumours which

delays the access of the reagents to the cells, coupled with their rapid elimination by the kidneys and bowels. This is one of the difficulties which is constantly met with in direct therapeutic experiments on cancer. The cancer cell is so like the normal cells of the body that agencies which destroy it are also dangerous to life.

Before we could plan, Sir William Church said, a rational method of treatment, it would be necessary to know more of the vital processes in cancer cells and the nature of the very delicate differences between them and the normal. A beginning has been made with the study of cell-respiration. Respiration is essentially a combustion process, oxygen being taken in and carbon dioxide given off. These are only the first and last terms, however, of a series of chemical equations, so that there is room for great variety in the intermediate stages, even if the final result should be the same. Dr. A. H. Drew had approached the problem by studying the rate of decolorisation of dilute methylene-blue solution by normal and cancer cells. With this method there is a wide difference between the two, decolorisation being much more rapid with normal cells. Dr. B. R. G. Russell and Dr. W. E. Gye have suspended the tissue emulsions in fully oxygenated defibrinated blood, and measured the rate at which oxygen is abstracted on incubation at body temperature. By this second method the differences are much less pronounced, and it is found that the more rapidly growing tumours, with significant exceptions, absorb more oxygen than those which grow slowly. The investigations are being continued, and give promise of interesting light on this fundamental feature of the life of cancer cells.

The adoption of the report was seconded by Sir JOHN BLAND-SUTTON.

Facilities Offered by the Fund.

The Duke of BEDFORD in moving a vote of thanks to the executive committee and others who have assisted in the work of the Fund during the past year referred to the wide range of investigation covering such important researches as those relating to (1) experimental induction of cancer; (2) respiration in normal tissues, which is a fresh line of research in connexion with cancer; and (3) experiments on the action of chemical substances on cancer cells in the test-tube and in the body, and the very technical investigation of the director on grafting. He noticed with satisfaction that the Fund is again in a position to assist investigators at home and abroad with tumour material for experimental purposes. Speaking of the finances of the Fund, he mentioned that increased expenditure was caused by the full resumption of laboratory research work as well as the enhanced cost of materials. The fixed income of the Fund was £5550, whereas the expenditure was £7000, the difference this year being met by a certain number of subscriptions and legacies. The Fund required at least £1500 a year more to maintain the researches. He referred to the valuable services of Sir Watson Cheyne, who had resigned the post of honorary treasurer, in which he was succeeded by Sir George Makins.

MEDICINE AND THE LAW.

Cremation and the Coroner.

In the City Coroner's Court recently Mr. F. J. Waldo held an inquest upon the body of a man who had been found unconscious on the pavement and had died after removal to St. Bartholomew's Hospital. Medical evidence was given to the effect that disease of the arteries of the brain was present, and that death was due to cerebral hæmorrhage. There was also evidence that the deceased suffered from financial difficulties and was depressed, although he had appeared to be in his usual health when he left home. Dr. Waldo called attention to the fact that he had to exercise additional care in holding this inquest owing to the fact that the body was to be cremated, and referred to the form which awaited his signature, in consequence of this, as imposing a heavy responsibility upon coroners. Undoubtedly it does so, but at

the same time the coroner in any case where suicide is suspected or possible can always safeguard himself by the evidence obtainable after post-mortem examination. Where there is reason to regard foul play as a possible cause of death it is, of course, incumbent upon him to obtain all evidence available to negative that possibility. Otherwise his duties are regulated by the Act of Parliament which imposes them, and as long as he complies with the requirements of the law no more can be expected of him.

Qualified Privilege or Malice.

At Leicester Assizes recently an action for slander and libel was tried before Mr. Justice Horridge and a special jury in which the plaintiff was Dr. J. T. Horron Davies and the defendant Eliza Lady Rolleston. The defendant's husband, Sir John Rolleston, who died early in April, 1919, of myocardial degeneration, was 72 years of age, and had for a long time been a patient of Dr. Davies. He returned from London to his house near Leicester shortly before his death very ill, and at the time of his death was being nursed by a trained nurse as well as by his wife. Shortly before Sir John Rolleston died Dr. J. D. Slight had been called in in consultation and had approved the treatment ordered, including the injection of sedatives, which had been rendered necessary by the patient's restless condition and impetuous temperament. It was not long after the administration of a subcutaneous injection of morphine and atropine that Sir John Rolleston died, and Lady Rolleston, who was distracted with grief and apparently under the impression that the injection had caused death, immediately accused Dr. Davies to his face before her brother-in-law and before servants of being responsible for the catastrophe. She also said to the nurse who administered the injection, "you and he planned it together." Presumably, as counsel observed in his opening speech, no public notice would have been taken by Dr. Davies of the utterances of a widow in the throes of grief, but six weeks later corresponding with Dr. Slight on the subject of her husband's death Lady Rolleston wrote: "Dr. Davies murdered him and all my friends agree with me. You can tell Dr. Davies or show him this letter. I don't care what you do in the matter." Dr. Slight appears to have communicated the contents of this letter to the plaintiff, who thereupon brought an action. In defence there was no plea of justification, the defendant not alleging that there had been wrongful or negligent treatment of the deceased, but "privilege" was claimed for the letter and utterances of the defendant. This plea the learned judge upheld, and left the case to the jury on the question whether there was malice on the defendant's part. The jury found a verdict for £100 damages, and judgment for that sum and costs was entered for the plaintiff.

With regard to the application of the protection of privilege to the occasions referred to above the ruling of the learned judge is not easy to understand. A statement made on an occasion of qualified privilege is *prima facie* protected, but proof of actual malice on the part of the defendant (the duty of proving such malice being on the plaintiff) will rebut the *prima facie* protection thus afforded. Qualified privilege exists on certain fairly well-defined occasions, among which are: (a) when statements are made with the object of protecting the writer or speaker to a person who has an interest or duty in connexion with the subject of the statement; (b) when the statement is made as to a matter in which there is an interest common to the writer or speaker and the person to whom the statement is made; (c) when statements are made in discharge of a legal, moral, or social duty. It is not altogether clear that (a) could apply or what interest there was common to Lady Rolleston and the gentleman who had advised in consultation with the plaintiff, or what duty Lady Rolleston had to communicate to him her opinion that the plaintiff was responsible for her husband's death. It may be, however, that the health of the patient and the result of the treatment were considered to be matters in which a common interest existed. As to the matter of duty, moreover, the question is what actually was the defendant's duty irrespective of any belief of the defendant that there was a duty to

make the statement. With regard to the question of malice, the use of excessively strong terms, more violent than the occasion demands, does not necessarily prove malice, but it has been laid down that "the language used in a libel, though under other circumstances justifiable, may be so much too violent for the occasion and circumstances to which it is applied as to form strong evidence of malice upon the issue of whether the communication is covered by privilege and an inference of actual malice may be drawn from its use." Lady Rolleston, no doubt, expressed an honest, and entirely mistaken, belief that her husband had been treated wrongly with fatal results in so vindictive a manner that it amounted to a charge of wilfully committed crime. Such language would constitute an abuse of the privileged occasion.

Poison in Sweetmeats.

At the recent York Assizes a trial was concluded the circumstances surrounding which have attracted some attention. The prisoner, Liddle, was indicted upon a charge of sending poisoned chocolates to a man named Thompson, a market gardener, and to seven other persons who had given evidence in an action arising out of a will in which he claimed an interest. This action had been decided against the prisoner, and the indictment was for sending the sweetmeats with intent to murder, and in an alternative count for sending them with intent to endanger life. Liddle, having been convicted on clear grounds upon the second count, was sentenced to ten years' penal servitude, with a concurrent sentence of five years upon other charges relating to the trial of the will case. The sending of poisoned sweetmeats to a person whom it is intended to injure is not a new idea, but savours in modern times rather of fiction than of fact. The case, however, should be a warning to persons receiving such gifts anonymously unless they have good reason to suspect a friendly donor. It is more easily conceivable that a malevolent person should seek to injure children, and through them to obtain revenge upon their parents, than that one man should send them to another for such a purpose. A market gardener would hardly, it might be thought, be able to avoid having his suspicions aroused by a gift of chocolates from someone unknown. The crime was, however, a very cruel one, and the punishment well deserved.

THE FEDERATION OF MEDICAL AND ALLIED SOCIETIES:

THE FIRST ANNUAL GENERAL MEETING.

The first annual general meeting of this Federation was held on Tuesday last, at 11, Chandos-street, London, Sir MALCOLM MORRIS, the chairman of the Executive Council, presiding. There was a good representative attendance. The annual report of the Council, adopted unanimously by the preceding business meeting, was taken as read.

ANNUAL REPORT OF THE EXECUTIVE COUNCIL, 1919-1920.

This, the first annual general meeting of the Federation, finds your Executive Council in the happy position of being able to report that much has been accomplished. Much more remains, however, for us to do.

The lines on which it was hoped to develop the constitution of the Federation were, it will be remembered, four in number:—First, that it should consist mainly of representatives of the existing associations and societies in the medical profession; secondly, that it should include representatives of the professions and occupations whose work is allied to medicine; thirdly, that it should link up the medical profession outside Parliament with the members of the profession inside Parliament; and, lastly, that it should include representatives of the whole medical profession as soon as its position warranted that step. Further, it was clearly understood that the Federation was *not* a body with a personal mission to lead the profession, but was designed to provide the medical and allied professions with the means of collective expression in the councils of the nation, to foster unity in the profession and closer relationship with the community, and to safeguard those high principles upon which the practice of medicine has been founded throughout its history. Recognising that opinions differ, it has been the aim of your Council to steer a middle course, and its members, representing as they do many spheres of medical activity, have worked together harmoniously and cordially for the general good.

Corporate and Associate Membership.

Forty-two distinct organisations are now coöperating in the Federation, 24 of these as corporate members and 18 as provisionally

represented bodies. In addition a number of others have at times sent representatives. The response from the professions and occupations whose work is ancillary to medicine has been remarkable—dental practitioners, pharmaceutical chemists, nurses and midwives are all represented by their chief organisations; sanitary inspectors and health visitors have offered their coöperation, and industrial medicine, hitherto largely neglected by us as a profession, has found its place within the wide horizon which encompasses the sphere of our interest.

Of the ten medical Members of Parliament (excluding one who, as a Cabinet Minister, is ineligible) nine have joined the Federation as honorary members, and the Medical Committee of the House of Commons has appointed its secretary, Captain W. E. Elliot, M.B., M.P., as its watching representative on the Executive Council. Sir Wm. Watson Cheyne has helped us in many ways and we owe much to the sympathetic coöperation that he and the other members of his Committee have given us. Lord Dawson of Penn, the first and only practising member of our profession in the House of Lords, has continued the support and sympathy which he has from the beginning given to the Federation.

The Council has given its support to two medical candidates for Parliament during the period under review, and was able to circularise all medical and dental practitioners, pharmacists, nurses, and midwives, and insert notices in the medical press, supply speakers, and provide cars for the poll.

The admission of Associate Members was commenced in March this year. A letter and pamphlet has been sent to most of the practitioners in the London district, and is now being sent to provincial practitioners. It has been found that the first issue brought in subscriptions sufficient to practically meet the cost involved, and as applications for membership are coming in in increasing numbers it is confidently expected that before long the limited income required will be available.

The main activities undertaken during the period have been the following:—

In October, 1919, a series of enquiries were sent to the societies coöperating regarding a possible medical service under the Ministry of Health, and designed to show how the interests of practitioners in the various branches of practice might be affected. The replies received have been valuable in the light of subsequent developments. The views of the societies were also obtained in regard to a Pure Milk Bill and other measures of impending legislation on which subsequent representations were made.

Conference on Medical Benefit Regulations.

On Dec. 12th, 1919, at a time when a very large section of the medical profession was much disturbed over the National Health Insurance Medical Benefit Regulations for 1920, a Conference was called at the request of certain of the constituent organisations to consider the higher questions of principle which were at stake and which were tending to be overlooked in the negotiations for higher remuneration. This Conference was productive of most useful discussion, and the following resolutions were adopted:—

1. That in the opinion of this Conference of medical and allied organisations the draft Regulations for 1920 proposed to be made by the Minister of Health with respect to the administration of the National Health Insurance Medical Benefit are not adapted to secure the most efficient service from the medical profession nor adequate results to the community.

2. That a Committee of Inquiry be asked for to take evidence and report.

3. That the resolutions of this Conference be conveyed to the Prime Minister and that he be requested to receive a deputation.

On Dec. 17th a deputation of six members of the Executive Council met the Medical Committee of the House of Commons in conference and secured the support of that Committee for the resolutions adopted at the Conference on Dec. 12th.

It was decided by the Executive Council that the first step in giving effect to the resolutions of the Conference should be to wait upon the Minister of Health, and that the deputation to the Prime Minister, which the Council had been assured would meet with a sympathetic attitude, should be deferred until the recommendations of the Medical Consultative Council of the Ministry had been made known.

On Jan. 23rd the Minister of Health received a strong deputation from the Federation, which was introduced by Sir Wm. Watson Cheyne, Bart., M.P., and was supported by the Right Honourable Sir Henry Craik, M.P., Sir Philip Magnus, Bart., M.P., and Lieutenant-Colonel F. E. Fremantle, M.P. The deputation placed before the Minister the reasons which appeared to necessitate an early, independent, and public inquiry into the working of the Medical Benefit under the Insurance Act. It was pointed out that the Medical Benefit under the Act has been in force for seven years, and that, although it constitutes the greatest experiment in public health legislation ever introduced, no facts are available upon which to judge of its success or failure. Dr. Addison accorded the deputation a most sympathetic hearing, and so far met it as to promise that such an inquiry as was asked for should be held if, on the issue of the Interim Report of his Medical Consultative Council, it could be shown that it would tend to instruct the public or the medical profession.

Support given to Constituent Organisations.

The support of the Executive Council has been sought by a number of representative organisations, notably by the British Dental Association, in urging upon the Secretary of State for War the minimal establishment necessary to secure an efficient permanent Army Dental Corps; by the British Science Guild in regard to State recognition and suitable awards for medical discovery; by the Medico-Psychological Association of Great Britain and Ireland in regard to the need of immediate legislation for the efficient treatment of mental disorders in their early stages; by the College of Nursing, Royal British Nurses' Association, and other representative nursing and midwifery organisations in regard to the need of nursing and allied services being directly represented on the Consultative Council of Medical and Allied Services of the Ministry of Health.

In each case the Executive Council has been able to render real service and its representations have met with a sympathetic reception at the hands of the Ministers concerned.

The Interim Report of Dr. Addison's Consultative Council, on the future provision of Medical and Allied Services, is now before the public and the professions concerned. The Executive Council has been able to give the Report preliminary consideration and has to acknowledge its indebtedness to the Minister of Health for his courtesy in supplying an advance copy, and to Lord Dawson for his readiness in answering many questions which have already arisen.

The necessary legal procedure in regard to the incorporation of the Federation is well forward and should be completed at an early date.

In conclusion, your Executive Council feels encouraged by the progress made in so short a time, which it thinks cannot be considered as other than satisfactory, and confidently looks forward to the future convinced that, continued on the lines originally laid down, the Federation cannot fail to foster greater unity in the medical and allied professions and bring them into closer and more sympathetic relationship with the great British public which they serve.

Signed for and on behalf of the Executive Council by MALCOLM MORRIS, Chairman; N. HOWARD MUMMERY, General Secretary.

A letter of regret was received by the general secretary from Dr. Addison, who wrote saying that pressure of Parliamentary work had put an embargo on all fresh demands on his time, and that it was not from any lack of goodwill that he did not attend the meeting.

CHAIRMAN'S ADDRESS.

Sir MALCOLM MORRIS then delivered an address reviewing the work of the Federation in the first year of its activity. He said:

Initial Success of the Enterprise.

We are not far from the beginning of the task to which we have put our hands; but the rapid accession to our ranks of numbers of the medical and kindred organisations which it is our aim to bring together for counsel and common action warrants the belief that our movement is destined to triumph. Our work has not been favoured by the heavy costs of all the facilities of communication, but this difficulty has been reduced to a minimum by the rigid economy that has been practised. So careful have our officers been that the expenditure for the first year has been kept within the estimate by more than £300, and their ingenuity has enabled them so to lay their plans that during the second year, without loss of efficiency, the expenditure will be still further reduced. That so much progress should have been achieved at so small an outlay is a most gratifying circumstance. As your chairman I should be guilty of gross remissness if I failed to pay a tribute to the work, as discreet as it has been energetic and enterprising, of the members of the Executive Council. They have spared neither time nor toil to further your interests, and I am sure that you will not be lacking in appreciation of their devoted and effective service.

That the evolution of this Federation conforms with the tendencies of the times is sufficiently obvious. The social instinct which prompts corporations to band themselves together for the attainment of common ends has been greatly stimulated as a result of the war. This, indeed, more than anything else, is the keynote of the national reconstruction which is now in progress. Alike in commerce and in industry, in employers and employed, we see a closing up of the ranks, while the nations themselves are striving to form themselves into a league as the one way of saving civilisation from shipwreck. Is it surprising, then, that the medical profession should strive after a Federation of the many organisations which represent its sectional interests, and should hold out the hand of fellowship to the bodies which represent the kindred professions?

The Need for Federation.

The need for such a Federation can be deduced only too easily from the experience of the last few years. Is it possible to maintain that when questions affecting the welfare of the great body of medical men have been before Parliament the profession has been able to pull its full weight? Was it so, for example, when the Health Insurance system was being framed? Certainly it was not. Who that cares supremely for the highest interests of the profession—and among those highest interests I rank its good repute—can look back upon the stormy events of those days without some sense of humiliation? The chattering in public into which the profession was forced was only too well calculated to give the impression that medical men were thinking very much of their material interests and very little of the nation's welfare. Had there been in existence such a body as the Federation is fast growing to be, how different would have been the beginnings of Health Insurance. The Government would have known at the outset that it had to reckon with a Federation through which were able to speak not only doctors, but also pharmaceutical chemists (who were immediately concerned) and related bodies which had no material interests at stake to deflect their judgment. How could the deliberate conclusions of such a Federation have failed to carry weight with the Government, and with that public opinion which is the final court of appeal.

The need for federation is deducible not less plainly from the multiplicity of existing medical organisations. That there are some 200 separate medical bodies certainly shows that the profession is not lacking in the organising faculty. But is it not evident that the effect of all this organising energy would be vastly strengthened if these 200 bodies were leagued together? They are influential in very different degrees. But were they all federated, the most powerful would have their influence increased tenfold; the least powerful would have their influence increased a hundredfold. These 200 organisations may all, for aught I know, be in the highest state of efficiency, but never will they be able to speak with unimpeachable authority until they have entered into a combination which will enable them to elicit their greatest common measure of agreement. This is no case merely of counting heads. We cannot, indeed, as practical men and women, afford to disregard the weight of numbers, but I attach far more importance to the moral authority which is implicit in the deliberate conclusions reached by men and women of different yet kindred professions who have taken counsel together and can speak not only for those whose interests are directly involved in a given issue, but also for those who can claim the quality of impartiality. No conclusions so arrived at could possibly be waived by the imputation of interested motives.

No Party Politics.

It cannot too often be insisted upon that the Federation knows no party politics. To say that it knows no politics would be absurd, for the most important of its objects is to take political action at every possible opportunity; but it gave its support—its active and influential support, I will say—to Lieutenant-Colonel F. E. Fremantle, who was elected as a Coalition Unionist, and to another member of the profession, Dr. Dunstan, who stood as a Labour candidate, and, though not at the top of the poll, won the second place in the list. And every medical Member but one of the legislature except Dr. Addison, whose office debars him from formal association with a movement with which he has none the less avowed his sympathy—including Lord Dawson, who can speak for us in the House of Lords—belongs to the Federation. The medical Members of the House of Commons now number ten, and we know that they are only the advance guard. Before long, with the active backing of the Federation, their numbers will be multiplied, and the time is at hand when, on all questions affecting health interests, the Whips will have to reckon with a solid phalanx of medical men who will be able to speak with one voice on public health, however much they may differ on other questions.

If any Government starves the Public Health Service we must cry "hands off," and a powerful medical group in the House of Commons will be a bulwark. Behind it will stand the Federation. No longer will it be a "grave defect in medical organisation," to use Dr. Addison's words, that there should be "no body of men in the profession who could be appealed to for judgment on a great public issue." Such a body the Federation is destined to become. That the system known as State medicine will undergo much further development is inevitable. The profession has no alternative but to adapt itself to the nation's needs, whatever form the adaptation may take. That task will require more statesmanship than is to be found in any one of the existing medical organisations, be it never so powerful. It is an enterprise which will tax to the uttermost the statesmanship of the whole profession. If that be so, how can any medical society or association be justified in withholding whatever contributions it can make to the common stock?

Constituent Bodies Maintain their Independence.

Finally, I protest, with all the emphasis at my command, that the Federation is absolutely innocent of any design to supersede the independent action of its constituent bodies. Every such body preserves its full powers of self-determination, and is as free to take individual action on any question as it was before joining the Federation. Naturally, having entered the Federation, it will present for discussion the views which it entertains on any matter of common interest. But whether those views secure the concurrence of the Federation or not it will be absolutely free to take whatever separate action it pleases. The Federation's first and greatest function is that of co-ordination. Its conferences will all be round-table conferences, in which no priority or predominance can or will be claimed by any. So far from running any risk of absorption, each of the constituent bodies will have its independence established on a more unassailable basis than ever; it will be able to justify its existence in the eyes of those to whom it is responsible by pointing to the results achieved by the allied action in which it has participated, results which will be far superior to any that could have been accomplished by its isolated efforts. The Federation, I boldly assert, has no prejudices, no rivalries, no antagonisms. Its aim is to provide a platform upon which all who are in any way responsible for the health of the nation can meet for free and equal conference with a view to united action.

DISCUSSION.

Captain W. E. ELLIOT, M.P., referring to the great help which the Federation of Medical and Allied Societies could give to Members of Parliament, never more necessary than to-day, said that there were a dozen great questions before the country, nearly all of which must result in some kind of legislative action. If the medical profession spoke unitedly their opinion would be irresistible, otherwise the layman would continue to take his own line of action.

Dr. ARTHUR LATHAM said he thought the Federation had been wise to include other than members of the medical profession in its membership. If the public had not learned to respect the opinions of the medical profession in the past it was due to the fact that the trend of medical discussions had led the public to think that doctors had been actuated by personal motives. The Federation desired nothing more nor less than the interests of the community. He was confident that if health questions were put upon a proper basis, something like that suggested by the Consultative Council, the medical profession with its allied bodies would receive adequate and proper treatment.

Dr. E. H. M. STANCOMBE said that as an individual the medical man was popular, powerful, and respected, but as a member of a public health body his opinion did not carry the weight which it should do.

Dr. HOWARD MARSHALL said that in these days it was difficult to give adequate treatment for serious cases in private houses. Let all hospitals have paying patients for all classes. He explained a system started in Cirencester some years ago which satisfied the people and which was almost self-supporting. The Federation could help to bring all the hospitals in the country into line.

Dr. BLACKHALL-MORISON thought that when voluntary hospitals were transformed into institutions charging fees of different rates subscriptions would cease to come in, and the hospitals would be unable to carry on.

Lord DAWSON of PENN said that in the past the medical profession had been criticised, with some justice perhaps, because it had shown itself unable to lead and to construct policies. This professional individualism was giving way before the necessities of the State and the medical calling was slowly emerging to the more collective point of view. The country had given it the opportunity of showing what it could do, and as a result the medical profession as a body was now looked upon with greater respect. One of the recent efforts on the part of medicine to take its proper public place was the Federation of Medical and Allied Societies, which thus aimed at approaching the difficulties of the future, while the Consultative Council was establishing a nexus between the Government and the medical profession. Some of those who criticised the report of the Consultative Council did not understand its real meaning, while others regarded it as frankly utopian. There was, in fact, a big situation to meet, a situation daily becoming more and more impossible, and in some way or other it had to be met. The medical critics did not recognise the gravity of the present situation or its increasing insistence. What would they put in place of the report? The only alternative was the nationalisation of medicine, whereas the spirit underlying the report was the provision of equipment, leaving the relation between doctor and patient free as before. The scheme was not intended for immediate realisation as a whole; it indicated the direction in which evolution might take place. To build intelligently the builder must first know what he wanted. If the medical reformer to-day had but 2 millions of money at his disposal he would not be so foolish as to fill the country with health centres, but would proceed with caution, acquiring the necessary experience. It was indeed time for the medical profession to think out clearly some organisation whereby this country was to be made healthy. Among the circumstances that would force the pace was the increased demand on the part of the public for better health. He could not recall an instance in which the press had taken such interest in a medical report as in that of the Consultative Council. Medicine would have to identify itself with local health work in each community, and one of the most essential recommendations in the report was that the medical profession should be represented on any new health authority brought into being. The nationalisation of medicine was already taking place while they were talking. There were school, tuberculosis, maternity, and other services set up because the voluntary organisation of the medical profession had not proved sufficient to meet the needs of the community. Proposals for the conduct of the new Bradford infirmaries were being made without adequate consultation with the medical profession; he was told that it was proposed to set up there a whole-time service, and what Bradford did to-day another city might do to-morrow. It might, of course, be the best policy to turn Poor-law infirmaries into a whole-time medical service, but the medical profession ought to realise the significance of this very definite move towards municipal service.

A vote of thanks to the chairman brought the proceedings to a close.

Correspondence.

"Audi alteram partem."

INDUSTRIAL SETTLEMENT FOR THE CONSUMPTIVE.

To the Editor of THE LANCET.

SIR,—In an article with this heading, which appeared in THE LANCET on May 8th, by Dr. P. C. Varrier-Jones and Sir G. Sims Woodhead, the authors say: "The newer conception of the duties of after-care and colony committees is based on the inclusion of the idea of partial if not complete separation or segregation of the tuberculous patient." Their plan is to establish industrial settlements in which the work is, of course, to be performed by sanatorium graduates who are to be paid for their work. The authors first discuss how such industries are to be started, but the statements are vague and no practical conclusions are reached. There is no discussion whatever of the economic questions involved—the subject is merely mentioned—and the commercial principle of supply and demand is wholly ignored. Their chief concern seems to be lest the reader think there will be difficulty in inducing consumptives to accept the gifts so lavishly offered. "Set up your industry and the people will flock to it, but in this instance let the industry be set up for consumptives; let it be run for their particular and special benefit and they will come—and stay." "Suitable work is by no means an unimportant factor in the treatment of the consumptive; indeed, it must be looked upon as the central pivot of the whole system."

The authors next consider skill as it now exists among workmen, and their conclusions are summarised fairly well in the following quotation: "We had first to realise that the working man of to-day has to be trained, in the majority of cases, not as the master of a trade but as a hand in a factory." Next they consider the working ability of sanatorium graduates: "Their strength is certainly diminished and their health impaired, but with encouragement and opportunity, both of which should be freely given, they will be able to contribute very materially to their own support and that of their families. The opportunity to work is what is required, and their earnings, together with a small pension, will in most cases enable them to become self-supporting, certainly to a much greater extent than were they compelled to enter into competition with the healthy worker in the outside world. The sapping of the moral character by gifts and doles should be carefully avoided." What about the pension?

The above quotations are sufficient to show, it is believed, that even from the standpoint of the believer in sanatorium treatment, the plan proposed by these authors is not only visionary and extravagant, but if it were found possible to put into practice the final result would be to pauperise the workers.

From the standpoint of the work of the Thompson Street Rooms, where ambulatory consumptive wage-earners are treated without interruption to work, and where graduates and those still undergoing active treatment are kept under control and observation for years, the practice of sending ambulatory consumptive wage workers first to a sanatorium and after to an "industrial settlement" is equivalent, in effect, to saying to each patient: "We will first remove your right arm, which interferes with your recovery, and then, after the wound has healed, educate you to become self-supporting and independent by giving you a pension and work suitable for a one-armed man." From this view-point the plan just considered is little short of wicked. I am, Sir, yours faithfully,

New York, June 12th, 1920.

JOHN F. RUSSELL, M.D.

To the Editor of THE LANCET.

SIR,—We are glad to have an early opportunity of correcting what appears to be a misapprehension on Dr. John Russell's part as to what is being done at Papworth. Apparently he does not recognise that what we wrote was the outcome of practical experience and that we are describing an industrial settlement not

built on the basis of a *château en Espagne*; the industries are already started and some practical conclusions are actually reached.

We were dealing, in our note, with the principles that underlie a large commercial undertaking in which the industries are run entirely for the benefit of consumptive working men, of whom 100 are already at work, and in connexion with which a considerable sum of money is passing through the hands of the business manager (a consumptive), the accounts being controlled and audited by an official auditor. This industrial colony is managed by and for consumptives, run on sound business lines and principles, in which consumptives in the colony village earn a full rate of wages for the number of hours they work, whilst others are being trained to follow in their footsteps. The turnover for these industries runs into five figures annually. In a booklet recently published we have anticipated the criticism contained in the first paragraph of Dr. Russell's letter:—

"Already the industries have a yearly turnover of many thousands of pounds. Serious work must be put in by all those employed; life is again given that zest which is all the more real and stimulating because it is triumphing over unfavourable circumstances. We compete in the ordinary markets with our goods. There is no undercutting, but, as manufacturers of articles for the wholesale trade, we fall into line with those who produce goods in the ordinary commercial way. To sum up, we might say that a colony takes and makes use of all that is good in industrial life, whilst rejecting or altering much that is detrimental to the welfare of the consumptive worker."¹

Whether this is "visionary and extravagant," and whether the "commercial principle of supply and demand is wholly ignored," your readers will be able to judge.

As regards Dr. Russell's reference to pensions, we look upon them as "earned," and we maintain that in the case of consumptives they should be continued not as a gift or a dole, but as a right—as something awarded to a damaged man without which he is unable to continue on the level at which he was working and living before he entered the war. If Dr. Russell will come and look at the Papworth Colony (or make inquiries from some of his fellow-countrymen who have already visited the colony) he will find that it is possible to put into practice the plan concerning which he has such doubts; that it is neither visionary nor extravagant; and that it does not pauperise the worker. It is not a question of "if it were found possible"; the scheme is an accomplished fact, a striking success.

We are glad to know that such good results are being achieved at the Thompson Street Rooms, and we wish Dr. Russell all success in his efforts, for if proper provision cannot be made for consumptive wage-earners it is well that they should be educated, advised, and controlled; but whatever may be done with them in the workaday world they will always be tempted to overwork, and must remain more or less active centres of infection to those who work and live with them.

Finally, we cannot agree that taking a man to a sanatorium deprives him of his right arm, but we do realise that such a patient has indeed already been damaged, so far as capacity to engage in many industrial occupations is concerned, far more than by the loss of that right arm.

As to the last line of Dr. Russell's otherwise moderate letter, we should like to ask him whether it is more *wicked* to help a man to live a decent life and to keep his family with the aid of a pension than it is to leave that man in the surroundings in which he has contracted or laid the foundation of the disease, knowing the chances are that, although he may continue to work, he is all along fighting against long odds, and, whilst losing ground, must continue to be a centre of infection to his family and his fellows. We leave that to your readers to determine.—We are, Sir, yours faithfully,

P. C. VARRIER-JONES.

G. SIMS WOODHEAD.

Cambridge, July 24th, 1920.

* * It seemed right to give those who were so strongly accused an immediate chance of reply.—ED. L.

SKIN AFFECTIONS AND GENERAL SYMPTOMATOLOGY.

To the Editor of THE LANCET.

SIR,—Your short reference to a paper read by Mr. Mollinson at the meeting of the British Medical Association at Cambridge, in which he says that septic conditions of the tonsils may be a source of various skin affections, such as psoriasis, touches the fringe of a large subject. Recently a child in good position, well cared for in all respects, was brought to me on account of psoriasis, which was rebellious to treatment. I found septic tonsils, and after these were removed the patient was cured.

But the pathology of psoriasis is practically unknown. Consequently the practitioner is debarred from frontal attack, and must ascertain in what way his patient, as a whole, departs from the normal. I believe it was Hebra who said that "psoriasis is a disease of the healthy." My own experience has taught me that if we can only investigate sufficiently, each victim of psoriasis will reveal some degree of pathologic deviation, which must be rectified before we can cure the disease. A large number of sufferers from psoriasis are chronically constipated. It is remarkable how many of these people are cured by the internal administration of petroleum, *provided the petroleum cures the constipation*. A Lane-Curtis belt is frequently a great help in bringing about this happy result.

Psoriasis is, of course, not the only affection of the skin that is profoundly influenced by a toxic state of the blood. In investigating any eruption, except those caused by known definite agents such as scabies and tinea, the first thing to do is to seek for any cause which may give rise to general systemic infection. The rôle played by carious teeth and pyorrhea in increasing the vulnerability of the skin can scarcely be over-rated, and in dermatological practice it should be part of the routine to examine carefully the buccal cavity. In innumerable instances obstinate skin affections have been cured by the intelligent treatment of the patient when classic methods of fighting the disease have failed.

I am, Sir, yours faithfully,

Birmingham, July 26th, 1920.

ARTHUR LOXTON.

THE INVESTIGATION OF RENAL EFFICIENCY.

To the Editor of THE LANCET.

SIR,—While we agree with Dr. Harrington Sainsbury that the body does fortunately possess to some extent the power of compensating for disease of a particular organ or system, we are of opinion that careful study of the diseased organ offers the most fruitful prospect towards successful diagnosis, prognosis, and treatment. The utilisation of other resources of the body has long been recognised, and any advance in the knowledge of such mechanisms cannot fail to be of value. Unfortunately, these extra resources are often of minor importance; indeed, it is doubtful whether certain functions of the renal system are at all exercised by other organs.

We would point out, however, that such a test as the estimation of blood urea affords an index, not only of the efficiency of the kidney, but also of the general power of the body to eliminate urea.

With regard to Dr. E. W. Dewey's questions: (1) We have not tried urea in the treatment of cardiac oedema, but its diuretic properties might very possibly be of use in this connexion in certain cases. (2) A salt-free diet, or at any rate a very sparing use of salt, should be advantageous on theoretical grounds, and in practice we have several times found that the combination of urea and a practically salt-free diet gave good results, in difficult cases. (3) We have not seen any instance of uræmia being precipitated in interstitial nephritis by the administration of urea, nor do we think this contingency at all likely to arise. In the first place, it is very doubtful whether urea *per se* takes any part in the development of uræmia; and secondly, in an advanced case, in which the possibility of uræmia might have to be taken into consideration, the retention of urea in the

blood is generally so great that its concentration would, relatively speaking, be only very slightly increased by a dose of 15 g. of urea administered by the mouth. From a large experience we are convinced that no danger exists in this direction.—We are, Sir, yours faithfully,

H. MACLEAN,
A. E. RUSSELL.

St. Thomas's Hospital, S.E., July 26th, 1920.

THE TUBED PEDICLE IN PLASTIC SURGERY.

To the Editor of THE LANCET.

SIR,—In various medical papers Major H. D. Gillies lays great importance to the discovery of the tubed pedicle. He claims in the *Journal of Surgery, Gynaecology, and Obstetrics*, February, 1920, to use his own words, "that he propounded the method in September, 1917."

If you, Sir, will refer to your issue of Dec. 15th, 1917, p. 889, you will see that in conjunction with the then Lieutenant G. S. Hett, on Nov. 12th, I performed the second stage of the operation, which consisted in sewing a chest pedicle together. This case is illustrated on p. 891. I distinctly recollect telling Major Gillies why I took this step, and have no recollection of his having done a similar operation previously.

I would draw Major Gillies' attention to the history of the double pedicle flaps to which he attaches so much importance. The first double pedicle flap at Sidcup was performed upon a man for deficient lower eyelid by myself. I transferred a stirrup flap from above to below the eye. Subsequently we found that Tripier had previously done a similar operation. I next made a large double pedicle flap from the throat and slipped it over the chin to make a lower lip in a man named McCrea. Major Gillies next did a converse operation, bringing down the scalp to the chin, and subsequently brought his chest flap up in a case of burn to the face. There are many who recollect this sequence of events, but the records are there for reference. In my work in the press, "Records of Plastic Surgery in Civil Life," I do not intend to enter into any disputes, but hope to depict the influence of war surgery on civil practice, leaving out all war cases and much of the pettiness connected with them. I am quite certain my late colleague will admit my contention in this letter once his attention is drawn to the same.

I am, Sir, yours faithfully,

J. L. AYMARD,

Late Plastic Surgeon, Cambridge Hospital, Aldershot,
and Queen's Hospital, Sidcup.

Globe House, St. George's-street, Capetown, July 1st, 1920.

MEDICAL EXPERIENCES IN MACEDONIA AND THE CAUCASUS.

To the Editor of THE LANCET.

SIR,—I am glad to find myself in full agreement with Professor L. S. Dudgeon's conclusions, as stated in his letter appearing in your issue of July 17th, that intramuscular injections of quinine may be regarded without apprehension provided it be recognised that serious troubles may arise unless the dangers, and how to avoid them, are fully understood. It would, indeed, have been surprising had we differed, seeing that the actual cases from which Professor Dudgeon's conclusions were drawn were for the most part the same that came under my own observation. Nearly all the ill-effects of intramuscular injections observed by Professor Dudgeon and enumerated by him in his article in the *Journal of Hygiene* were assignable to some error in technique and come under the category of preventable complications.

Considering the many thousands of injections given in Macedonia, the very small number of cases in which such ill-effects followed is a testimony, as Professor Dudgeon observes, to the recuperative power of the tissues; it also goes far to prove the point for which I was contending, that those who employed this method of treatment were alive to the risks, and with rare exceptions were successful in the precautions they took to prevent complications.

I am, Sir, yours faithfully,

Weymouth-street, W., July 19th, 1920.

A. G. PHEAR.

The Services.

ROYAL ARMY MEDICAL CORPS.

Majors to be acting Lieutenant-Colonels: H. T. Wilson, R. N. Hunt.

To be Captains: Temp. Major J. H. Spencer; Capt. W. E. K. Coles (late R.A.M.C.), E. O. A. Singer (from Spec. Res.).

L. Handy and J. W. Malcolm, late R.A.M.C., Spec. Res., to be temporary Captains.

Temp. Lieut. J. F. P. Gallagher to be Lieutenant.

B. McB. Richardson to be temporary Honorary Lieutenant.

Officers relinquishing their commissions:—Temp. Major A. L. B. Green (retains the rank of Major); Temp. Capt. S. Stockman (granted the rank of Major); Temporary Captains retaining the rank of Captain: I. M. Grant, J. M. Mitchell, H. R. S. Walford, A. McK. Bell, C. Stanley-Clarke, W. B. U. Patterson, A. P. Adams, P. E. B. Barrow, S. H. Pitcairn, A. M. Masters, J. D. Judson, S. D. Craig; Temp. Hon. Capt. B. M. Richardson (retains the honorary rank of Captain).

Capt. W. N. Greer, R.A.M.C. (S.R.), and Temp. Capt. D. V. O'Malley, R.A.M.C., have been appointed Officers of the Military Division of the Most Excellent Order of the British Empire for valuable services rendered in connexion with military operations in Burma.

TERRITORIAL FORCE.

Lieut.-Col. C. I. Ellis to be Deputy Assistant Director of Medical Services, Wessex Division, with the pay and allowances of a Major.

Capt. L. T. Challenor to be Deputy Assistant Director of Medical Services, South Midland Division.

Lieut.-Col. A. G. Hamilton to command 4th Cheshire Cavalry Field Ambulance.

Majors to be Lieutenant-Colonels and to command as stated: A. E. Jerman (4th London Field Ambulance), A. A. W. Merrick (3rd West Lancs. Field Ambulance), T. Kay (2nd Scottish Casualty Clearing Station), E. C. Stack (6th Stafford Cavalry Field Ambulance), F. W. Bailey (1st West Lancs. Field Ambulance), J. G. Martin (2nd West Lancs. Field Ambulance), W. Archibald (2nd Eastern Casualty Clearing Station), C. R. White (3rd Western Casualty Clearing Station).

Surg.-Major C. O. Parsons, from R.G.A., to be Lieutenant-Colonel and to command 2nd Welsh Field Ambulance.

Captains to be Lieutenant-Colonels and to command as stated: H. F. W. Boeddicker (1st Southern Casualty Clearing Station), F. Darlow (2nd Northern Casualty Clearing Station), G. L. Thornton (1st Wessex Field Ambulance), F. A. Roper (2nd Southern Casualty Clearing Station), H. F. Everett (1st East Anglian Field Ambulance), T. B. Wolstenholme (2nd Western Casualty Clearing Station).

Major L. C. V. Hardwicke to be acting Lieutenant-Colonel whilst specially employed.

Majors T. D. Brown and D. R. Dobie resign their commissions and retain the rank of Major.

Capt. P. W. G. Sargent resigns his commission and is granted the rank of Colonel.

Capt. F. J. M. Kennedy and D. M. Marr resign their commissions and retain the rank of Captain.

Capt. J. Barkley and J. R. Menzies to be Majors.

Capt. A. G. Wilson, from 3rd Northern General Hospital, to be Captain.

TERRITORIAL FORCE RESERVE.

Major H. Richardson, from R.A.M.C. (General List), to be Colonel; Capt. C. W. Eames, from General List, to be Lieutenant-Colonel; Capt. C. N. Smith, from General List, to be Major.

Capt. K. S. Storrs resigns his commission and retains the rank of Captain.

ROYAL AIR FORCE.

The undermentioned have been granted permanent commissions, subject to physical fitness and to acceptance of conditions of service when promulgated:—

Wing Commanders: H. V. Wells, C. E. C. Stanford, A. W. Iredell, H. Cooper, A. V. J. Richardson, J. McIntyre, M. W. Flack.

Squadron Leaders: H. M. S. Turner, E. C. Clements, W. W. Shorten, W. A. S. Duck, B. A. Playne, R. H. Knowles, H. A. Treadgold, J. MacGregor, H. A. Hewat, H. B. Porteous, T. S. Rippon, F. N. B. Smartt, H. E. Whittingham, D. Ranken.

Flight Lieutenants: A. S. Glynn, A. E. Panter, H. W. Scott, P. M. Keane, T. J. Kelly, R. S. Overton, D'Arcy Power, J. Rothwell, K. Biggs, A. J. O. Wignmore, J. H. Porter, A. F. Rook, T. C. St. C. Morton, G. S. Marshall, E. W. Craig, R. A. G. Elliott, T. J. Thomas, P. H. Young, R. S. Topham, T. R. S. Thompson, P. C. Livingston, P. J. Flood, J. T. T. Forbes, J. Kyle, C. T. O'Neill.

The following promotions are made:—

Squadron Leaders to be Wing Commanders: H. M. S. Turner, E. C. Clements.

Flight Lieutenants to be Squadron Leaders: A. S. Glynn, A. E. Panter, H. W. Scott, P. M. Keane.

The undermentioned are granted short service commissions, subject to physical fitness and to acceptance of conditions of service when promulgated:—

Squadron Leaders (whilst so employed): R. L. Roe, H. Harvey, F. C. Jobson.

Flight Lieutenants: E. P. Punch, E. N. H. Gray, R. E. Bell, C. H. B. Thompson, E. A. Lumley, D. G. Boddie, R. J. Aherne, W. F. Wilson, F. J. P. Saunders, W. A. Malone, F. J. Murphy, H. McW. Daniel, A. E. Barr-Sim, P. A. Hall, H. B. Troup, R. Mugliston, J. C. Smyth, J. P. Hosford, J. J. O'Mullane, J. P. Wells, T. Montgomery, A. Briscoe, E. G. O'Gorman, T. J. X. Canton, W. F. Shiel, A. Watson, C. H. Young.

Flight Lieut. F. J. P. Saunders is seconded for duty with the Director of Research.

The following officers are granted short service commissions in the ranks stated:—

Flight Lieutenant: E. P. Hardman.
Flying Officers: J. B. Allen, V. P. Feather, J. Talbot.
Observer Officer: W. W. Bradford.
Flying Officer S. G. Frogley resigns his short service commission and is granted the rank of Flight Lieutenant.

TERRITORIAL DECORATION.

The Territorial Decoration has been conferred upon the under-mentioned officers: Lieut.-Cols. J. W. Leitch (1st Lowland Field Ambulance), M. Dunning (2nd Lowland Field Ambulance); Majors G. W. Fitzgerald (1st East Lancs. Field Ambulance), A. W. French (3rd London (City of London) Field Ambulance), W. G. Sutcliffe (attached 3rd Home Counties Brigade, R.F.A.), J. Leach (Highland Mounted Brigade Field Ambulance), H. G. F. Dawson (attached Welsh Divisional Engineers), B. Riddell (3rd Scottish General Hospital); Capt. L. B. Cane (attached Inns of Court O.T.C.).

FOREIGN DECORATIONS.

French.

Médaille des Épidémies "d'Or."—Maj. G. H. J. Brown, D.S.O., R.A.M.C.; Capt. H. Lightstone, D.S.O., M.C., R.A.M.C. (T.F.).

Médaille des Épidémies "en Argent."—Maj. G. P. A. Bracken, R.A.M.C.; temp. Capt. J. F. Broughton, M.C., R.A.M.C.; Capt. D. Mackie, M.C., R.A.M.C. (S.R.); Capt. C. J. L. Patch, M.C., I.M.S.; temp. Capt. A. G. Whitehorn-Cole, R.A.M.C.; temp. Capt. A. W. Young, M.C., R.A.M.C.

Médaille des Épidémies "en Bronze."—Temp. Lt. W. S. Baird, R.A.M.C.; temp. Capt. H. R. Dew, R.A.M.C.; temp. Capt. J. E. Paterson, R.A.M.C.

Serbian.

Order of St. Sava: 4th Class.—Maj. G. Ashton, T.D., R.A.M.C. (T.F.); temp. Capt. P. Black, R.A.M.C.

URBAN VITAL STATISTICS.

(Week ended July 24th, 1920.)

English and Welsh Towns.—In the 96 English and Welsh towns, with an aggregate civil population estimated at nearly 18 million persons, the annual rate of mortality, which had been 9.9 in each of the three preceding weeks, fell to 9.8 per 1000. In London, with a population of nearly 4½ million persons, the annual death-rate was 9.1, or 1.0 per 1000 below that recorded in the previous week, while among the remaining towns the rates ranged from 1.8 in Cambridge, 4.4 in Preston, and 4.9 in Wallasey and in Dewsbury, to 17.0 in Enfield, 17.1 in Tynemouth, and 17.7 in Great Yarmouth. The principal epidemic diseases caused 192 deaths, which corresponded to an annual rate of 0.6 per 1000, and comprised 91 from infantile diarrhoea, 42 from diphtheria, 29 from measles, 20 from whooping-cough, 7 from scarlet fever, and 3 from enteric fever. Measles caused a death-rate of 1.2 in Rhondda and 1.4 in Warrington, but the mortality from the remaining diseases showed no marked excess in any of the towns. There were 1911 cases of scarlet fever and 1556 of diphtheria under treatment in the Metropolitan Asylums Hospitals and the London Fever Hospital, against 1855 and 1582 respectively at the end of the previous week. The causes of 27 of the 3342 deaths in the 96 towns were uncertified, of which 5 were registered in Birmingham.

Scotch Towns.—In the 16 largest Scotch towns, with an aggregate population estimated at nearly 2½ million persons, the annual rate of mortality, which had been 11.1, 12.1, and 11.1 in the three preceding weeks, rose to 11.6 per 1000. The 274 deaths in Glasgow corresponded to an annual rate of 12.8 per 1000, and included 11 from infantile diarrhoea, 9 from small-pox, 2 each from measles and diphtheria, and 1 each from enteric fever and whooping-cough. The 87 deaths in Edinburgh were equal to a rate of 13.3 per 1000, and included 2 from infantile diarrhoea and 1 from diphtheria.

Irish Towns.—The 102 deaths in Dublin corresponded to an annual rate of 12.8, or 2.9 per 1000 below that recorded in the previous week, and included 3 from whooping-cough, and 1 each from measles and infantile diarrhoea. The 92 deaths in Belfast were equal to a rate of 11.6 per 1000, and included 3 from infantile diarrhoea, 2 from diphtheria, and 1 each from scarlet fever and whooping-cough.

TYRONE COUNTY INFIRMARY.—At a meeting of the Co. Tyrone Hospital Committee, held in Omagh on July 10th, it was stated the deficit for the present year was estimated as being about £2500, but as the accounts had not yet been audited the county council could not be asked to meet this deficit. The effort to raise £700 of debt (which cannot be recouped by the county council) was reported as proceeding satisfactorily; and when this sum is found the Committee will get £900 from the Red Cross Society. The amount of the £700 already received is £400. It was agreed to increase the salary of the nursing sisters to £70 per annum, the officers to get an increase of 15 per cent. on their present salaries, and the servants and the nurses to receive an addition of 25 per cent.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

The Care of the Blind.

THE Bill introduced by Dr. ADDISON, Minister of Health, to promote the welfare of blind persons in the United Kingdom, was considered by a Standing Committee of the House of Commons on Thursday, July 22nd, Sir WATSON RUTHERFORD in the chair.

On Clause 1, in answer to criticisms to the effect that the Bill did not go far enough, Dr. ADDISON pointed out that over 50 per cent. of the blind would be automatically included within the operation of this clause, and of the remainder one-third were children under 16 years of age. Under Clause 2, if amended as he would propose later, it would be the duty of county and county borough councils, instead of being optional as originally contemplated, to make provisions for the maintenance and training of all blind persons. The Government proposed that 50 per cent. of all capital expenditure of those authorities in regard to the provision of workshops and so forth should be provided by Exchequer grants. In addition they would continue grants in respect of training, and would make maintenance grants to institutions in respect of persons trained. He thought that it was better to proceed in this way than by granting pensions in a wholesale manner. On a division Clause 1 was agreed to by 16 votes to 9, and Dr. ADDISON then moved the new subsection to Clause 2, to which he had previously referred. The subsection was agreed to. A further amendment proposed by Dr. ADDISON requiring that local authorities should make suitable provision for the technical education of blind persons was also adopted. The Committee stage of the Bill was concluded, and the measure as amended was ordered to be reported to the House.

Dangerous Drugs Bill.

The Dangerous Drugs Bill, a measure prepared to give effect to the International Opium Convention signed at the Hague in 1912, was considered by a Standing Committee of the House of Commons on Tuesday, July 27th. Colonel W. G. NICHOLSON was in the chair.

Sir J. BAIRD, Under Secretary for Home Affairs, moved an amendment to Clause 7 which deals with the control of the manufacture or sale of cocaine, morphine, and other drugs, providing that regulations under the section should provide for authorising any person who lawfully kept a shop for retailing poisons under the Pharmacy Act, 1868, as amended by the Poisons and Pharmacy Act, 1908, (a) to manufacture at the shop in the ordinary course of his retail business any preparation, admixture, or extract of any drug to which Part 2 of the Act applies, or (b) to carry on at the shop the business of retailing, dispensing, or compounding any such drug, subject to the power of the Secretary of State to withdraw the authorisation in the case of a person convicted of an offence against the Act or of an offence under the enactments relating to the customs as applied by the Act, and who could not in the opinion of the Secretary of State properly be allowed to carry on the business of manufacturing or selling or distributing any such drug. The Secretary of State, before withdrawing the authorisation, is bound to consult the Council of the Pharmaceutical Society of Great Britain. Nothing in any regulations made under the section is to be taken to authorise the sale or keeping of an open shop for the retailing, dispensing, or compounding of poisons by any person who is not qualified under the provisions of the Pharmacy Acts or to be in derogation of the provisions of those Acts for prohibiting, restricting, or regulating the sale of poisons. The amendment was agreed to.

Sir J. BAIRD moved an amendment to Clause 13, which deals with offences and penalties, to the effect that a person guilty of an offence under the Act should be liable on summary conviction to both fine and imprisonment and in the case of a second or subsequent conviction to a fine not exceeding £500, or to imprisonment with or without hard labour for a term not exceeding two years, or to both such fine and imprisonment, and the court dealing with the case may, in addition to any other punishment, order the goods in respect of which the offence was committed to be forfeited. The amendment was agreed to.

Sir J. BAIRD moved another amendment to Clause 13, providing that any proceedings for an offence against the Act before a court of summary jurisdiction might, notwithstanding any enactment prescribing the time within which such proceedings might be brought, be brought either within the time so prescribed or within three months from the date on which evidence sufficient in the opinion of a Secretary of State to justify a prosecution for the offence came to his knowledge, whichever was the longer, and a certificate purporting to be signed by the Secretary of State as to the date on which such evidence came to his knowledge should be

conclusive evidence thereof. In the application of the subsection to Scotland the Lord Advocate, and in its application to Ireland the Attorney-General for Ireland, should be substituted for a Secretary for State. The amendment was agreed to.

Sir J. BAIRD moved a new clause providing that any constable might arrest without warrant any person who had committed or attempted to commit, or was reasonably suspected by the constable of having committed or attempted to commit, an offence against the Act, if he had reasonable ground for believing that that person would abscond unless arrested, or if the name and address of that person were unknown to and could not be ascertained by him. The clause was agreed to.

On the motion of the Attorney General for Ireland (Mr. HENRY), a new clause was agreed to to the effect that in the application of the Act to Ireland (a) a reference to The Poisons (Ireland) Act, 1870, The Pharmacy (Ireland) Act, 1875, and The Pharmacy (Ireland) Act, 1875 (Amendment) Act, 1890, should be substituted for any reference to The Pharmacy Act, 1868; and (b) a reference to the Pharmaceutical Society of Ireland should be substituted for the reference to the Pharmaceutical Society of Great Britain. The clause was agreed to.

The Committee stage of the Bill was concluded and the Bill was ordered to be reported to the House.

HOUSE OF COMMONS.

WEDNESDAY, JULY 21ST.

Report of Birth-rate Commission.

Lieutenant-Colonel FREMANTLE asked the Minister of Health if he had considered the Second Report of the Birth-rate Commission; and what steps he proposed to take to secure constant consideration in future of the practical problems involved.—Dr. ADDISON replied: I have seen the Report in question. All statistical aspects of the matter are kept under continuous review by the Registrar-General's Department, now working in close relation to the Ministry. Any steps that are desirable and practicable will be taken, but I am not clear as to any special action by the Ministry that is called for at the present time.

Venerable Diseases Officer at Bury.

Captain LOSEBY asked the Minister of Health whether the position of venerable diseases officer at Bury, Lancashire, a part-time appointment of nearly £350 a year, had been given to an applicant who did not join up for service in the war; whether 15 applications were received; whether the three selected for interview possessed at least equal academic status and experience to the one chosen for the position; whether these three applicants had each been over four years in the army and had served overseas; whether, seeing that, other qualifications being equal, an important public post, paid for out of Government funds, should be given to a man who had served in the Forces, and the appointment must be ratified by the Ministry of Health, what action he proposed to take in the matter.—Dr. ADDISON replied: I have not yet received any application for approval of this appointment, but I am communicating with the Bury town council in the matter.

Association of British Girls with Orientals.

Brigadier-General SURTEES asked the Secretary for the Home Department whether his attention had been called to the state of things existing in the East-end of London, as well as in a number of seaport towns, in consequence of the association of young British girls with Chinamen, negroes, Indians, and others of Oriental race, an association often leading to rioting and other evils; and what steps, if any, he intended to take in the matter.—Mr. SHORTT replied: I am aware that last year some disturbances arising from this cause occurred at Cardiff and other seaports, but no serious trouble of a similar character has come to my notice during the present year; and I find on inquiry that in East London there has only been one incident worth mentioning, when several arrests were made. If there should be any further trouble of this sort the police will deal with it as they would deal with any other disturbance of the peace.

Disabled Men's Complaint at Woolwich.

Mr. L'ESTRANGE MALONE asked the Minister of Labour whether his attention had been called to the fact that many disabled ex-Service men at Woolwich were being deliberately given work which aggravated their disabilities or which their disabilities prevented them from doing efficiently; and would he send an independent investigator to examine the evidence on this subject which was in the possession of the Woolwich branch of the National Union of Ex-Service Men.—Dr. MACNAMARA replied: My attention has not been called to any cases of this kind, but if particulars are supplied to me I shall be glad to make inquiry. I cannot imagine that it is true that disabled men are deliberately given work which aggravates their disabilities.

Officers and Nurses held up at Alexandria.

Lieutenant-Colonel WALTER GUINNESS asked the Secretary for War whether troops and nurses on their way home for demobilisation had been waiting in certain cases at Alexandria since the month of April; whether he could state what was the reason of the delay; and what steps were being taken to deal with it.—Sir A. WILLIAMSON (Financial Secretary to the War Office) replied: I have recently caused full inquiries to be made into the allegations that officers and nurses have been detained for long periods at Alexandria awaiting passages, and from the reports recently received it appears that, although there has been delay, it has been unavoidable. In a report received at the end of June it was stated that no officers or nurses had been awaiting passage for as long as three months, and only three officers had been awaiting passage for more than five weeks. On June 19th there were 127 officers in the camp altogether awaiting passage and 52 nurses, and a special ship was arranged for the transport of these. As regards other ranks I am informed that there has been no delay whatever in their embarkation from Egypt since May last, as the third-class accommodation available has more than met the requirements.

THURSDAY, JULY 22ND.

Neurasthenia Treatment in Ireland.

Sir ROBERT WOODS asked the Minister of Pensions if it was the case that for the three southern provinces of Ireland the only institution for the treatment of discharged soldiers suffering from neurasthenia was Leopardstown Park, county Dublin; if the accommodation was limited to 35 patients; if there were at present awaiting admission there 248 men for whom treatment in that place had been recommended; and, if so, what steps he proposed to take to provide adequate accommodation for these distressing cases.—Mr. MACPHERSON replied: The facts are substantially stated in the question. Arrangements are, however, in progress to provide accommodation at Leopardstown Park for an additional 50 patients, and the question of providing further facilities for the treatment of this class of patient is engaging my earnest attention. I need scarcely remind my honourable friend that there are considerable local difficulties to be contended with, but I can assure him that everything possible will be done to meet the situation.

Deaths of War Pensioners.

Mr. TYSON WILSON asked the Minister of Pensions if he would give the number of persons who, having been granted pensions owing to injuries or disease caused by the late war, had died since the pension was granted them.—Mr. MACPHERSON replied: The approximate number of officers is 800 and of other ranks 30,000.

Pension Curtailments and the Medical Boards.

Captain BOWYER asked the Minister of Pensions whether he was aware that numerous cases of complaint had arisen with regard to the cutting down of the pensions of disabled soldiers irrespective of, and without apparent reference to, the awards of medical boards; would he state on what principle such pensions were cut down; and would he undertake that in future where the disability remained constant or increased that the pension should also either remain constant or be increased proportionately to the increased disability.—Mr. MACPHERSON replied: I am not aware of the numerous cases of complaint suggested in the question. All awards of pension under the Royal Warrant are in accordance with the findings of the medical boards by whom the pensioners are examined and no alteration is made in a board's original estimate of the degree of a man's disablement without further reference to the board, or the authority of a superior board after a fresh examination of the man. The present practice is, in fact, in accordance with the suggestion made in the last part of my honourable and gallant friend's question.

FRIDAY, JULY 23RD.

Experiments on Living Animals.

Sir J. BAIRD moved an address for a "return showing the number of experiments on living animals during the year 1919 under license granted under Act 39 and 40 Vict. Cap. 77 distinguishing the nature of the experiments."

MONDAY, JULY 26TH.

National Registration Acts.

Sir BURTON CHADWICK asked the Minister of Health if he would state what was the present position of the scheme of national registration; whether it was being kept up to date; for what purpose; and at what cost.—Dr. ADDISON replied: The National Registration Acts legally remain in operation until the official termination of the war. The answer to the second question is in the negative and the remaining questions do not arise.

Medical Examinations for Service Pensions.

Sir WATSON RUTHERFORD asked the Minister of Pensions whether a man who applied for a service pension was to be subjected to a fresh medical examination; and whether there were numerous cases where the service pension now granted was accompanied by such a reduction of the disability pension that both put together did not exceed the total amount formerly drawn on the disability alone.—Mr. MACPHERSON replied: The regulations regarding "service" pensions in addition to disablement pensions vary according to the length and nature of the man's service, and I regret that it is not therefore possible to give a comprehensive answer to this question. If my honourable friend has any specific cases in mind I shall be glad to give him full information on receiving the regimental particulars.

Medical Men at the Ministry of Health.

Sir J. D. REES asked the Minister of Health whether 32 doctors at £1000 a year were now to be appointed to work under his direction.—Dr. ADDISON replied: Yes, Sir. They are appointed to act as referee consultants under the National Health Insurance Scheme, with the object of protecting insurance funds from unnecessary claims to sickness benefit and improving the general standard of insurance medical practice. Funds for this purpose were voted by Parliament in 1914, but not spent during the war, owing to the impossibility of establishing this much needed extension of the Health Insurance Medical Service during that time.

TUESDAY, JULY 27TH.

Alleged Maggoty Flour at Macclesfield.

Mr. REMER asked the Food Controller whether his attention had been called to a statement by Councillor Webster, of Macclesfield, that a quantity of flour had been stored at the Beehive Mill, Bollington, since the early part of the war; that this flour was maggoty and unfit for human food; that the Ministry of Food had issued instructions that this flour should be sold locally owing to the cost of transport; and that a large quantity was at the present moment being sold to bakers in the borough of Macclesfield; whether these facts were correct; if so, whether he would take steps to prevent the distribution of food unfit for human food; and, if the statement was incorrect, whether he would cause the statement to be denied.—Mr. McCURDY replied: My attention has been called to the statement in question, which is untrue in every particular. There is no ground whatever for this aspersion upon the conduct of the efficient officers whose duty it is to inspect at regular monthly intervals the stocks of flour belonging to the Royal Commission on Wheat Supplies lying at warehouses and mills.

Health of the Troops in Mesopotamia.

Mr. LAMBERT asked the Secretary for War if the health of the British troops in Mesopotamia was satisfactory, and if he could state the ratio of sickness among the forces in Mesopotamia as compared with those in the United Kingdom.—Mr. CHURCHILL replied: For the first three months of this year the health of the British troops in Mesopotamia was very satisfactory, the sick-rate being less than that in the United Kingdom. In April, the last month for which complete figures are available, the admission-rate per 1000 of strength rose owing to the seasonal incidence of sandfly fever, giving an annual ratio of 890.4 per 1000, compared with 644.6 per 1000 in the United Kingdom. The incidence of sandfly fever increased during May and June, but is now declining rapidly.

Welfare Work in Factories.

Sir BURTON CHADWICK asked the Minister of Health if he would state what steps were taken to maintain and stimulate the welfare work in factories initiated during the war.—Mr. SHORTT (Home Secretary) replied: The Home Office obtained statutory powers in 1916 to make Orders requiring the provision of welfare arrangements in factories, and a number of such Orders have been made for different classes of works dealing with the provision of mess-rooms and cloak-rooms, washing facilities, first-aid and ambulances, and other matters. The factory inspectors enforce these orders, and it is also part of their ordinary routine when visiting works to investigate the welfare conditions and to promote the development of welfare work. The Home Office has also endeavoured to assist and stimulate voluntary action on the part of employers. A series of official pamphlets has been issued explaining the principles on which welfare work is based and dealing with it in detail in its different aspects. Conferences have been held with representatives of the Universities, of employers and workpeople, of welfare workers and others on the important question of the selection and training of welfare workers, and generally on the development of welfare work. When opportunity has offered the subject has also been pressed on the attention of the Joint Industrial Councils. I

am glad to state that the reports of the factory inspectors show that a widespread and increasing interest is being taken in this work and that steady progress is being made in the introduction and improvement of welfare arrangements.

Decisions of Medical Appeal Tribunals.

Mr. CHARLES EDWARDS asked the Minister of Pensions if he was aware that great dissatisfaction existed among ex-Service men through the decisions of the medical appeal tribunals, which deprived them of any further pensions notwithstanding the fact that many of these men were now unable to do the same work as before and were only able to do work of a less arduous nature at much lower wages than their former employment would now bring them in; whether many were discharged as totally unfit for further service, yet the result of the appeal tribunal was the same; if he would state how these tribunals were appointed; whether they were permanently employed by the Ministry; and what instructions were given them with reference to these examinations; and whether he would set up another tribunal with power to fully investigate the former condition of these men as regards health, for comparison purposes when the final examination was being made, and thus endeavour to give the greatest possible satisfaction to men who had so strong a claim upon the nation.—Mr. MACPHERSON replied: I am not aware of any grounds for thinking that the arrangements for appeal to medical appeal boards, to which presumably my honourable friend refers, are working otherwise than satisfactorily. These boards were constituted to give both disabled men and the Ministry the advantage of the advice of specialists in the various diseases of disability, and a specialist is always a member of an appeal board. Members are appointed by the Minister, and apart from the Deputy Commissioner of Medical Services of the area, who is a whole-time officer, they are remunerated on the basis of a fee per session. None of the members are in the permanent employ of the Ministry. No special instructions have been given to the appeal boards which would interfere with their unfettered judgment on the merits of each case that comes before them, and, in the circumstances, I see no advantage in constituting a new tribunal as suggested by my honourable friend. With regard to the ground of complaint alleged, I would remind my honourable friend that the accepted basis of the award of disablement pension is the medical estimate of the extent of the disablement consequent upon the disability which has been found to be due to the man's war service. Considerations as to the wages which a pensioner is capable of earning (which under the present system are expressly excluded from the assessment of pension) could not reasonably be introduced in those cases only where they would be to the man's advantage.

Imports and Exports of Extract of Male Fern.

Mr. WILLIAM GRAHAM asked the President of the Board of Trade whether he could state the exports and imports in the year 1913 of the extract of male fern technically described as ext. filicis liq. or ext. filicis maris, and what were the returns of export and import for the first six months of the present year, or for such post-war period as might be available; and whether such exports and imports were subject to any special arrangements giving preference to the products of any country.—Mr. BRIDGEMAN (Parliamentary Secretary to the Board of Trade) replied: In the year 1913 the value of the imports into the United Kingdom of extract of male fern was £739. I am unable to state the total value of the exports of this commodity during that year, or of either imports or exports during any post-war period, and I do not feel justified in having such particulars compiled, in view of the considerable expenditure of time which would be involved in the process. Extract of male fern is not dutiable, and no question of preference on the importation of the extract arises, but when it is imported dissolved in dutiable spirit preference is accorded on the dutiable ingredient if the latter is of Empire origin. No preference is given on the export of any goods.

Vaccination and the Glasgow Small-pox Outbreak.

Mr. ROBERT YOUNG asked the Secretary for Scotland, in reference to the Glasgow small-pox outbreak, whether any of the small-pox cases or deaths given in the return to July 12th, 1920, as unvaccinated had been vaccinated at any time either before the development of the disease or during the course of the disease; and, if so, would he give particulars.—Mr. MUNRO replied: In the return mentioned the classification of "unvaccinated" and "vaccinated" is determined by the condition at the date of exposure to infection. Of the 88 cases included under the heading "unvaccinated" 15 were vaccinated between exposure to infection and the development of the disease, 14 successfully and 1 unsuccessfully. Of these 15 cases 2 died. One was a child aged 2 months, who had been successfully vaccinated, and the other was a child aged 6 years, who was unsuccessfully vaccinated four days before the disease developed.

Medical News.

UNIVERSITY OF SHEFFIELD.—The following students have passed the Third M.B., Ch.B. examination held recently:—

Edgar S. Clayton, Mary P. Gell, Ronald D. S. Inman, Richard T. Lee, Elsa F. Paige, Robert Platt (distinction in Pathology), and Percival H. Sharp.

ROYAL COLLEGE OF SURGEONS OF EDINBURGH.—At a meeting of the College held on July 22nd the following gentlemen, having passed the requisite examinations, were admitted Fellows:—

Harold Benge Atlee, James Clark Bell, Frederick Cameron, Alexander Rae Campbell, Frederick Ernest Feildon, Joseph Anthony Ferriere, Trevor Gayer Fetherstonhaugh, Thomas Watson Hancock, Sydney Lawrence Harke, William Knox Irwin, George Brownlee Isdale, Hugh Hunter Jamieson, Colin King, James Tait M'Auslin, Anthony John M'Creadie, William Archibald Mein, Abdul-Chani Neguib Misbah, Duncan Metcalfe Morison, George Thomson Mowat, William Graham Oakeley, Guy Harcourt Peall, Hugh Noel Murray Puckle, Matthew Edward Robinson, Robert Joseph Silverton, Andrew Fulton Sinclair, Francis William Stone, Frans Karel Te Water, and Cecil Uren.

LONDON SCHOOL OF TROPICAL MEDICINE.—The following are the results of the examination held at the end of the sixty-third session (May to July, 1920):—

*T. J. D. Lane ("Duncan" medal), *R. Jamison (P.M.O., Swaziland), *Miss E. J. O'Driscoll, *F. E. Reynolds, M. D. Mackenzie, J. M. MacKay (West African Medical Service), R. B. Hawes, J. Glavina (Malta), J. Forrest (Major, I.M.S.), V. E. Critien (Malta), S. A. Eldaab, J. V. Holmes, G. C. R. Wilson (Tanganyika Territory), and J. H. Parry (Tanganyika Territory).
* With distinction.

CENTRAL MIDWIVES BOARD FOR IRELAND.—The Board held their first examination for midwives on July 8th and 9th simultaneously at the Royal College of Surgeons, Dublin, the Queen's University, Belfast, and University College, Cork. Dr. Trevor N. Smith, Dr. Reginald G. White, Dr. Gerald Tierney, Dr. J. M. Gilmor, Dr. J. D. Williamson, Dr. John McLeish, Dr. John Booth, and Dr. Walter Rahilly acted as examiners. Seventy-three candidates presented themselves for examination, of whom 62 passed. The next examination takes place in October.

Dr. Mary Baird, now school medical officer at Torquay, has been selected as assistant medical inspector of schools in Natal.

Messrs. Cassell and Co. announce the early appearance of a seventh edition of Hutchison and Rainy's "Clinical Methods," and a fifth edition of Mr. Comyns Berkeley's "Handbook of Midwifery."

MEDICAL SICKNESS, ANNUITY, AND LIFE ASSURANCE SOCIETY, LIMITED.—The first ordinary general meeting of the company will be held at Lincoln House, 300, High Holborn, London, W.C., on August 23rd, at 4.45 p.m.

Edwin Smith, M.D. Lond., barrister-at-law, deputy coroner for Westminster and South-West London and lecturer on forensic medicine at St. Thomas's Hospital, has been appointed coroner for the North-Eastern District of London.

OWING to present economic conditions the Council of the School Dentists' Society has decided to discontinue the printing of separate *Transactions* and to supply instead a copy of the *British Journal of Dental Science* to each of its members. Mr. A. E. Baker, the editor of the *Transactions*, will act as dental editor and deal with correspondence and papers relating to school dentistry.

At a recent meeting at Plymouth of the South-western Centre of the Sanitary Inspectors' Association Dr. A. B. Soltau, chairman of the Plymouth Public Health Committee, urged the importance of having milk graded in this country, and of making it impossible for any retailer or producer to send out for consumption milk which is bacteriologically contaminated.

Dr. James Miller, who has been appointed professor of pathology at Queen's University, Canada, graduated M.B. in 1899, saw service in South Africa with the Edinburgh and East of Scotland Hospital, and during the recent war was pathologist to the 2nd Scottish General Hospital. In 1902 he was appointed lecturer in bacteriology in the University of Birmingham, returning to Edinburgh in 1909 as lecturer in pathology and bacteriology to the School of Medicine of the Royal Colleges and to the Edinburgh School of Medicine for Women. For about ten years he has acted as pathologist at the Royal Infirmary and other Edinburgh hospitals.

BELFAST HOSPITALS BUSY.—In connexion with the disturbances in Belfast the hospitals have been busy with gun-shot rifle wounds, scalp injuries, and body contusions. At the Royal Victoria Hospital during last week-end about 25 cases were admitted with gun-shot wounds and 16 deaths occurred arising out of the riots.

A WELSH CHAIR OF TUBERCULOSIS.—On the occasion of the Royal visit to open the sanatoriums of the Welsh National Memorial Association at Langwyfan in North Wales and at Talgarth in South Wales, the announcement was made by the president, Major David Davies, that a chief medical officer would shortly be appointed, who would also be professor of tuberculosis in the Welsh National School of Medicine. The position, with 15 institutions containing over 1100 beds to direct, a staff of 24 medical officers, and a medical school developing entirely on the unit system, will be unique.

PRESENTATION TO DR. T. RIDLEY BAILEY, OF BILSTON.—The medical practitioners on the Staffordshire panel entertained Dr. T. Ridley Bailey, chairman of the County Panel and Local Medical Committees, to luncheon on July 23rd. The Mayor of Stafford, Dr. F. Milnes Blumer, presided. After luncheon Dr. Bailey was presented with a gold cigarette case and a cheque.

MICHELL CLARKE MEMORIAL FUND.—This fund, opened in 1918, to collect a sum to commemorate the services of the late Professor John Michell Clarke to the cause of medical education in Bristol, has reached a total at which it will be possible, after paying for the publication of a volume reprinting some of his published writings, to devote about £1000 to the endowment of a fund for the purchase of books and periodicals on clinical medicine for the Bristol Medical Library. Should any friends of Professor Michell Clarke still wish to add to this fund they should address contributions to Mr. James Rafter, Registrar, University of Bristol.

VETERINARY SURGEONS AND QUACKERY.—Mr. W. Scott, F.R.C.V.S., presiding at a meeting at Bristol of the recently formed Mid-West of England and South Wales Veterinary Association, said that quacks were thriving on the credulity of animal owners, using drugs of which they knew nothing upon their dumb patients, of whose structures they had no scientific knowledge. The loss to the animal owner and State through this malpractice must be colossal, and Government legislation was urgently demanded. Animals were protected from cruelty, but there was nothing done to protect them from quackery and maltreatment.

THE PLYMOUTH MEDICAL CHARITIES.—The Committees of the South Devon and East Cornwall Hospital and the Royal Albert Hospital have decided that in future, although necessitous cases will be treated free of charge, a minimum charge of half a guinea weekly will be charged for in-patient treatment, and a charge of 6d. for each attendance after the first, including accident cases. These fees have been rendered necessary owing to the financial position of the charities.

LIVERPOOL SCHOOL OF TROPICAL MEDICINE.—On Saturday, July 24th, the Sir Alfred Jones laboratories of the Liverpool School of Tropical Medicine were formally opened by Lord Leverhulme. The proceedings were presided over by Sir Francis Dawson, chairman of the school, who stated in his introductory remarks that the laboratories had been built and equipped by funds placed at the disposal of the committee by the executors of the late Sir Alfred Jones—the founder and staunch friend of the school. In an eloquent speech Lord Leverhulme paid a high tribute to Sir Alfred Jones as a man of indefatigable energy and large vision, and stated that his work on behalf of tropical medicine was his best monument. The laboratories, which were completed just before the war, were in use until last year as a military hospital, devoted specially to cases of malaria and other tropical diseases. Since being handed back by the War Office they have been repainted and decorated, and the function of Saturday marked their formal opening. Situated in Pembroke-place, within easy reach of the Royal Infirmary and the University, the laboratories are commodious and up to date. On the ground floor there is an excellent museum, the exhibits in which excited great interest among the guests at the opening function, a lecture room, and a well-equipped library. The higher floors are devoted to laboratories for research and instruction. In the evening Sir Francis Dawson gave a banquet in the Exchange Hotel to over 100 guests, when tribute was paid to the work of the tropical school, and hopes were expressed for the work to which it is setting its hand.

A SOMERSET SUPER-CENTENARIAN.—Mr. F. W. Stabbins, of Worle, near Weston-super-Mare, has recently celebrated his 105th birthday.

IN recognition of his long and distinguished connexion with the David Lewis Northern Hospital the committee of that institution has established a special department for the study of neurology, which is to be called "The W. B. Warrington Department for Nervous Diseases." This is generally regarded as a fitting tribute to the memory of one who did much pioneer work in this branch of medicine while honorary physician there.

DEATH OF DR. ARTHUR SHEPHERD.—The death took place at Shethin, Tarves, on July 19th, of Arthur Shepherd, M.B., Ch.B. Aberd., Major, R.A.M.C., youngest son of the late Mr. George Shepherd, of Shethin. He was educated at the Aberdeen Grammar School and University, where he graduated in 1907, joining the R.A.M.C. in the same year. About 10 years ago he was sent to India and during the war he was in Mesopotamia with the Expeditionary Force. While abroad he contracted malaria and to a recurrence of the fever, when home on leave, his death is attributed. Major Shepherd was 35 years of age and unmarried.

THE LATE DR. R. M. SMYTH.—Dr. Robert Milner Smyth, assistant medical superintendent of Addington Hospital, Durban, Natal, was found dead in his bedroom by a native servant early in the morning of Wednesday, June 23rd. Death is certified to have been due to heart failure. Dr. Smyth was born in Dublin on Dec. 10th, 1868, and received his professional training at the Royal College of Surgeons, Ireland. Going out to Natal in 1898 he had served 22 years at the Addington Hospital, where he won a high reputation as a surgeon, and was socially very popular. He served with the British Forces in the Boer War in the capacity of civil surgeon, and he also saw service in the Natal Native Rebellion of 1906, and held medals and clasps for both campaigns. In the late war he served through the campaign in German S.W. Africa as O.C. No. 3 General Hospital, Northern Force, Swakopmund, and was promoted lieutenant-colonel, South African Medical Corps. Afterwards he was medical embarkation officer at the port of Durban, and was also in charge of the military section of Addington Hospital. For these services he was given the O.B.E. The funeral took place at Durban, and was accorded military and Masonic honours.

THE HOSPITALS OF DEVON.—The first meeting of the Devon Joint Committee of the British Red Cross Society and Order of St. John for the co-ordination of voluntary nursing and similar service was recently held at Exeter, when Sir Napier Burnett gave an interesting address. He stated there were 21 Poor-law infirmaries in Devon with 1484 beds, 19 or 20 infectious diseases hospitals with 469 beds, and 40 voluntary civil hospitals, including dispensaries, with 1160 beds. This made a total of 80 hospitals, 3113 beds, representing 4.44 beds for each 1000 of the population. The ratio for the beds in the voluntary civil hospitals was 1.65 per 1000, and this was nearly sufficient in an agricultural county with a scattered population, but in an industrial centre like Plymouth it should be about 3 per 1000. Sir N. Burnett remarked that broadly speaking Devon was not badly off for hospital accommodation, and also alluded to the fact that the Poor-law infirmaries in this country were more than half empty, adding that in one city there were 1000 vacant beds in these institutions, while in a civil hospital in the same city there was a large list of cases waiting for admission.

POOR-LAW MEDICAL OFFICERS' ASSOCIATION.—At the annual meeting of the association, held in London on July 15th, a discussion on Changes in the Poor-law Medical Service was introduced by the chairman of council, Dr. A. Lionel Baly, medical superintendent of the Lambeth Infirmary, who suggested that medical practitioners should be allowed to treat their own patients after removal to the infirmary. He held that there was nothing wrong with the Poor-law itself, but that it needed to be rightly administered. Dr. A. Withers Green, honorary secretary of the association, read a paper showing the increasing tendency to take the care and treatment of the sick out of the hands of the part-time district medical officers and to place it in those of the whole-time infirmary medical staff. The consequences which would result from this limitation were fully discussed, and the following resolution was passed unanimously:—

We, the Poor-law Medical Officers' Association of England and Wales, view with alarm the attempt now being made in some quarters to eliminate part-time district medical officers, to the disadvantage, we maintain, of the sick poor, and to place Poor-law treatment into the hands of whole-time resident medical officers in the various infirmaries. We consider it inadvisable that changes in this description be made till such time as the whole subject has been carefully considered and the best scheme for the general welfare has been decided upon.

A copy of the resolution is being sent to the Ministry of Health and to each of the boards of guardians in England and Wales.

MANCHESTER SMOKE SCREEN.—Under the presidency of Lord Newton, the Government Departmental Committee on Smoke and Noxious Vapours Abatement held two public meetings in Manchester last week. Apart from its effect on the health of the community, smoke is said to cause a loss of £1,000,000 annually in Manchester, and the question is what changes in the law in regard to pollution of the air would be likely to materially improve matters and lessen the heavy annual tax on health and property. Half of the smoke screen was alleged to be due to domestic fires, and consequently witnesses, bore testimony to the rival claims of gas and electricity for heating and domestic purposes. A cloud of witnesses testified to the magnitude and urgency of the evil, but the remedies suggested were few. The law already provides certain safeguards, but it was alleged that various local authorities were very lax in applying such rules the law prescribes; hence suggestions arose that instead of the regulations being left to be applied by the local authorities, they should be carried out by Government officials. Farmers complained of the deleterious effects of chemical fumes in the neighbourhood of Runcorn, others of the disastrous effects on their crops and cattle, and all the witnesses of the ineffectiveness of the inspection under the Alkali Act and of the difficulty of obtaining compensation for losses suffered. Pieces of muslin curtains, which had been hung in different parts of the city for periods of 7 to 14 days were all more or less black from the effects of smoke and emissions from chemical works. As to the health aspect, smoke by intercepting the direct rays of the sun made people more readily liable to tuberculosis, while fogs increased the mortality from phthisis, pneumonia, and bronchitis. It was suggested that in addition to local smoke inspectors there should be other inspectors appointed by the Ministry of Health with power to institute proceedings independently. The committee besides taking evidence visited some works in the district.

ABERDEEN UNIVERSITY COURT.—At the recent meeting of the Aberdeen University Court, Principal Sir George Adam Smith presiding, the secretary intimated receipt of a legacy of £250 from the representatives of the late Dr. Albert J. Venn, of London, who graduated at Aberdeen University M.B. in 1872 and M.D. in 1875. He also reported receipt of a gift of £250 for the medical school from the executors of the estate of the late Mr. James Munday. The offer was accepted of a stained-glass window for the University, bequeathed by the late Mrs. Shand, widow of Professor Smith Shand, who occupied the chair of medicine in Aberdeen University for a long period. The Court decided to instal electro-cardiographic apparatus within the Faculty of Medicine. Dr. R. D. Lockhart, was appointed a lecturer in anatomy. It was agreed to institute a full-time lecturer in bacteriology within the department of pathology.

PRESENTATIONS TO MEDICAL MEN.—On the occasion of his retiring from the post of senior honorary surgeon to the Liverpool Stanley Hospital, Mr. F. C. Larkin was last week presented with a testimonial by a number of his medical and surgical friends. The testimonial took the form of an address, a copy of one of Haig's etchings, and a cheque. The presentation was made by Sir James Barr at a special meeting held in the Liverpool Medical Institution. The Hospitals Committee of the Liverpool City Council made its annual inspection of the hospitals last week, and at the luncheon at Fazakerley Hospital the opportunity was seized to present Dr. Claude Rundle, who has been superintendent of the institution for the past 14 years, with a silver salver and a Georgian cake-dish on the occasion of his recent marriage.

A MEDICAL CENTENARIAN.—Dr. James Scarth Spence Logie, who died at Kirkwall, Orkney, on July 17th, in the 101st year of his age, was a son of the late William Logie, D.D., minister of St. Magnus Cathedral. He was educated at the Grammar School, Kirkwall, and Edinburgh University, and qualified L.R.C.S. Edin. in 1841, graduating the following year M.D. Edin. After qualifying he was for a short time an assistant in Carlisle before going for further study to Paris, returning to Kirkwall, whence his practice soon extended over the whole of Orkney. When he started practice there were no made roads in the islands, nor, with the exception of farm carts, wheeled vehicles. His professional visits were made on horseback over rough hill tracts or in small sailing-boats to the neighbouring islands, which in rough weather entailed constant danger. Dr. Logie, who had been medical officer to the Balfour Hospital, Orkney, and to the prison at Kirkwall, was also medical officer of health for that town. He completed his 100th year on May 12th last, when he was the recipient of letters and telegrams from the King, the Senatus of the Edinburgh University, and from the General Assembly of the Church of Scotland, of which he had been ordained an elder in 1855. Dr. Logie is survived by a daughter.

Appointments.

Successful applicants for vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to THE LANCET Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.

BROADWAY, T. B., M.B., Ch.B. Glasg., has been appointed Public Vaccinator for Dorchester.
BROMLEY, L. M.Ch., F.R.C.S., Surgeon to the Neurological Department, Guy's Hospital.
DAWE, J. H., M.B., C.M. Edin., Assistant Medical Officer at the Devon and Cornwall Sanatorium for Consumptives, Didworthy, Dartmoor.
GABRIEL, W. B., M.S. Lond., F.R.C.S. Eng., Assistant Surgeon to St. Mark's Hospital for Diseases of the Rectum, City-road, E.C.
KENDREW, A. J., M.C., M.B., B.S. Lond., L.R.C.P., M.R.C.S., Honorary Surgeon to the North Devon Infirmary, Barnstaple.
SHEEN, A. W., C.B.E., M.S. Lond., F.R.C.S., Visiting Surgeon (for General Surgery) to Ministry of Pensions Hospitals, Orpington and Shepherd's Bush.
Certifying Surgeons under the Factory and Workshop Acts: BURNELL, G. F. (Truro); SPONG, J. F., M.R.C.S. Eng. (Tooting); YEOMAN, W. M., M.B. Durh. (Stokesley, North Riding).

Vacancies.

For further information refer to the advertisement columns.

Aberdeen University.—Lecturer in Bacteriology. £500. Also Asst. in Path.
Bath City.—Asst. M.O.H. and Asst. Sch. M.O. £550.
Battersea General Hospital (Incorporated), Battersea Park, S.W.—Res. M.O. £200.
Birkenhead Borough Hospital.—Jun. H.S. £200.
Birmingham General Dispensary.—Res. M.O. £400.
Birmingham University.—Lect. in Physiology. £250.
Bolingbroke Hospital, Wandsworth Common, S.W.—H.S. £150.
Bournemouth, Royal Victoria and West Hants Hospital.—Res. M.O. £200.
Bradford City Hospital, Leeds-road.—Asst. M.O. £350.
Bristol Royal Infirmary.—Non-Res. Anesth. £100.
Chester Royal Infirmary.—H.P. £150.
City of London Hospital for Diseases of the Chest, Victoria Park, E.—Res. M.O. £250. Also H.P. £100.
Colchester, Severalls Mental Hospital.—Asst. M.O. 7 gs. per week.
Colonial Service.—M.O.'s for West African Medical Staff, Government Service in Malaya, East African Protectorates, West Indies (including British Guiana), Fiji, and the Western Pacific, &c.
Covey Education Committee.—Two Sch. Dentists. £500.
Croydon General Hospital.—Second H.S. £150.
Derby County Borough Education Committee.—Asst. Sch. M.O. £500.
Derby, Derbyshire Education Committee.—School M.O.'s. £550.
Dumfries and Galloway Royal Infirmary.—Res. H.S.
Fulham Metropolitan Borough.—M.O. £1 11s. 6d. per session.
Gartnavel, Glasgow Royal Asylum.—Asst. M.O. £300.
Gloucester, Gloucestershire Royal Infirmary and Eye Institution.—H.P. £175.
Hereford County and City Mental Hospital.—Jun. Asst. M.O. £350.
Hull Royal Infirmary.—Asst. H.S. £150.
Isle of Ely County Council.—Clin. Tuberc. O. and Asst. M.O.H. and Sch. M.O. £600.
Johannesburg, South African Institute for Medical Research.—Asst. Bacteriologist. £800.
King's Lynn, West Norfolk and King's Lynn Hospital.—Res. M.O. £150.
Leasow Hospital for Children, Cheshire.—Jun. M.O. £200.
Leeds City Tuberculosis Sanatorium, Killingbeck.—Res. Asst. M.O. £300.
Leeds General Infirmary.—Res. Surg. O. £200.
Leicestershire and Rutland Mental Hospital, Narborough, near Leicester.—Jun. Asst. M.O. £300.
Leith Hospital.—H.S. and H.P. £100.
Lincoln County Hospital.—Jun. H.S. £150.
Liverpool, David Lewis Northern Hospital.—Two H.P.'s and Three H.S.'s. £120. Also Asst. M.O., V.D. Dept. £150.
Liverpool, Fazakerley Sanatorium.—Asst. Res. M.O. £300.
Liverpool, Royal Children's Hospital.—Hon. P. and Hon. Asst. S.
Liverpool School of Tropical Medicine.—Three Medical Men for Clinical and Research Work in Tropical Medicine.
Llanelli Borough.—M.O. and Schools M.O. £750.
London Jewish Hospital, Stepney Green, E.—Clin. Asst. £70.
London Temperance Hospital, Hampstead-road, N.W.—Asst. Res. M.O. £120.
Louth Union.—M.O. £180.
Maidstone, Kent County Mental Hospital.—Jun. Asst. M.O. £300.
Maidstone, West Kent General Hospital.—H.S. £250.
Manchester Children's Hospital, Pendlebury, near Manchester.—Two Res. M.O.'s. £150.
Manchester, City of.—M.O. £450 and war bonus of £307 15s. 6d.
Manchester, Crosseley Sanatorium, Delamere Forest, Cheshire.—Asst. M.O. £350.
Manchester, Hulme Dispensary, Dale-street.—H.S. £400.
Manchester, Monsall Fever Hospital.—Sec. Med. Asst. and Third Med. Asst. £300 each.
Middelee Hospital, W.—Cas. M.O. £2 a week.
Miller General Hospital for South-East London.—H.S. £150.
Newcastle-upon-Tyne, Hospital for Sick Children.—Jun. Res. M.O. £200.
Preston Royal Infirmary.—Res. M.O. £180.

Queen Charlotte's Lying-in Hospital, Marylebone-road, N.W.—Asst. Res. M.O. £60.
St. Mark's Hospital for Cancer, Fistula, and Other Diseases of the Rectum, City-road, E.C.—H.S. £250.
St. Thomas's Hospital Medical School, Albert Embankment, S.E.—Demonstrator of Anat. £400.
Sheffield, East End Branch of the Children's Hospital.—H.S. £150.
Sheffield Royal Infirmary.—H.P. £150. Also Hon. M.O.
South London Hospital for Women, South Side, Clapham Common, S.W.—Female H.S. £100.
Southport General Infirmary.—Sen. H.S. and Jun. H.S. £250 and £175 respectively.
Stafford, Staffordshire General Infirmary.—H.S. £250.
Stockport General Infirmary.—Jun. Res. S. £200.
Sunderland Royal Infirmary (Children's Hospital).—Female Jun. Res. M.O. £150.
Swansea General and Eye Hospital.—Jun. H.S. £200.
Swindon Borough.—M.O.H. and Med. Supt. of Isolation Hospital. £900.
Taunton and Somerset Hospital.—Sen. and Jun. H.S.'s. £200 and £150 respectively.
Tiverton Hospital, Devon.—H.S. £100.
West End Hospital for Nervous Diseases, 73, Welbeck-street, W.—H.P. £250.
Windsor, King Edward VII. Hospital.—H.S. £200.
Worcestershire County Council.—Asst. County M.O.'s and Sch. Oculist. £500 each.
The Chief Inspector of Factories, Home Office, S.W., gives notice of a vacancy for a Certifying Surgeon under the Factory and Workshop Acts at Loughor.

Births, Marriages, and Deaths.

BIRTHS.

HEWITT.—On July 19th, at Pelton Holme, Ben Rhydding, Yorkshire, the wife of R. Conrad Hewitt, M.R.C.S., L.R.C.P., of a daughter.
PAYEY-SMITH.—On July 25th, at 9, Victoria-avenue, Harrogate, the wife of A. B. Paye-Smith, M.C., F.R.C.S., of a son.
WILSON.—On July 23rd, at Putney-hill, S.W., the wife of Alex. Wilson, M.D., of a son.

MARRIAGES.

KENNAWAY-DERRY.—On July 24th, at Christ Church, Lancaster-gate, Ernest Laurence Kennaway, M.D., D.Sc., to Nina Marion Derry, younger daughter of the late William Derry, of Birmingham, and Mrs. Derry.

DEATHS.

McGHIE.—On July 23rd, at Bongate House, Appleby, Robert McGhie, M.D., of Oaklands, Mountain Ash, and of Trows, Lesmahagow, aged 50 years.
SANDILAND.—On July 7th, suddenly, Arthur Henry Sandiland, M.R.C.S., L.R.C.P., of 137, Southgate-road, London, N., aged 73 years.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

LONDON HOSPITAL MEDICAL COLLEGE.

MEDICAL UNIT, in the Clinical Theatre of the London Hospital, E.

A Course of Twelve Lectures on Neurology, open to Students and Graduates of the London Hospital and other Schools—

TUESDAY, August 3rd.—2 P.M., Lecture VII.:—Dr. Riddoch: Disorders of Sensibility from Lesions of Thalamus and Cerebral Cortex.

WEDNESDAY.—2 P.M., Lecture VIII.:—Dr. Thompson: Polyneuritis.

WEST LONDON POST-GRADUATE COLLEGE, West London Hospital, Hammersmith, W.

TUESDAY, August 3rd.—12 noon, Mr. T. Gray: Demonstration of Fractures, &c. 4.30 P.M., Mr. Addison: Practical Surgery. I.

WEDNESDAY.—11.30 A.M., Mr. MacDonald: Demonstration of Cystoscopy. 4.30 P.M., Dr. Simson: Gynaecology.

THURSDAY.—10.30 A.M., Dr. Simson: Gynaecological Demonstration. 4.30 P.M., Dr. G. Stewart: The Sympathetic Nervous System.

FRIDAY.—12.15 P.M., Dr. Burnford: Applied Pathology. 4.30 P.M., Mr. B. Davis: Clinical Lecture:—I., Throat and Ear.

SATURDAY.—12 noon, Mr. Sinclair: Surgical Diseases of the Abdomen.

Daily:—10 A.M., Ward Visits. 2 P.M., In-patient, Out-patient Clinics and Operations.

MALE LOCK HOSPITAL, Dean-street, W.

MONDAY, August 2nd, WEDNESDAY, AND FRIDAY.—5 P.M., Dr. C. Russ: Demonstration of the Treatment of Gonorrhœa by Electrolysis.

CANCER HOSPITAL, Fulham-road, S.W.

Clinical Lectures on the Diagnosis and Treatment of Cancer.

FRIDAY, August 6th.—4.30 P.M., Mr. P. P. Cole: Cancer of the Lips and Jaws.

Communications, Letters, &c., to the Editor have been received from—

A.—Dr. J. L. Aymard, Cape Town; Actors' Orphanage, Lond.

B.—Dr. F. J. H. Bateman, Lond.; Mr. G. Bethell, Lond.; Dr. J. Brown, Blackpool; Miss Bligh, Paris; Lt.-Col. Sir J. W. Barrett, Melbourne; Sir J. Byers, Belfast; Mr. J. Burns, Edinburgh; Col. R. J. Blackham, Bearsted; Dr. W. C. Bosanquet, Lond.; Dr. W. Bell, Lowestoft; Mr. T. R. Brown, Sheffield.

Notes, Short Comments, and Answers to Correspondents.

DISEASES AND SOCIAL HABITS.

Sir Humphry Rolleston, in a recent address on "The Change of Type of Disease," has pointed out that "the varying resistance of the population to disease is concerned with both the periodicity of disease and the character of the epidemics," and, further, that "the resistance of individuals and races is obviously influenced by environment, such as overcrowding, overwork, bad food, and alcoholism, and thus both the incidence and the severity of the disease—conditions which must be distinguished from each other—become increased." Diseases, in fact, are prone to rise and fall as do empires, and the habits of men have much to do with these changes. In a charming book, "Sussex in Bygone Days," noticed in these columns on the occasion of the author's recent death, the late Mr. Nathaniel Paine Blaker, a well-known Brighton practitioner, reviewed the changes in social habits observed by him in the course of a long life in their influence on disease types. Two such changes—namely, growing temperance and respect for ventilation—have during the last 50 or 60 years been factors in the improvement of national health. In the earlier half of the last century, and, indeed, to well within living memory, the idea prevailed that night air was a carrier of disease by means of what was known as "miasma," and that at all costs it must be excluded from sleeping-rooms. According to Mr. Blaker the superstition dated from the days before coal came into general use, and arose out of the difficulty of warming the air, while disease was generally believed by our ancestors to be air-borne.

In compiling the lives of some 2000 medical men, whose activities lay in the period 1820–1920, Mr. Victor Plarr has had occasion to note that the careers of individuals practising in town and country are in some degree a reflection of changes in the social habits of their patients. In the earlier part of this selected period medical men worked hard, lived hard in a sense, and died comparatively young. Up to about the "eighties" of last century they mostly died soon after attaining the age of 60. For some reason or other 62 was for a long period the age at which the country practitioner departed this life. After the eighteenthies there occurs a marked change, and octogenarians become increasingly frequent. Mr. Blaker himself was 83 when he died on March 12th, 1920. The old physicians and surgeons prescribed stimulants and often took them themselves. Their patients drank a vast amount, and the short life and the merry one was in many cases the order of the day. It is a question, indeed, now that stimulants, especially wine, are too expensive to be freely indulged in by educated men whether life does not promise to become, not short and merry, but a *longueur*, punctuated by financial anxieties, carping tempers, and a constant pessimism. The word "fun," so common in old biographies, is not now heard or written. One is almost tempted privily to envy the old gentleman of 94 who told Mr. Blaker that he attributed his excellent health at a great age to his moderation in the matter of wine. "I was always very careful, I never drank much wine," said the venerable Mr. New, of Southwick, to his chuckling professional friend. "Five or six glasses at dinner, and the same after dinner, but I used to drink punch from 6 o'clock at night to 6 o'clock next morning." Like their patients the old country doctors probably never felt quite warm in winter. Wool was not worn; flannel was regarded as effeminate wear. Their glow was rather internal than external as they rode for miles on horseback or with numbed limbs on the top of a coach. The cold bath, or, indeed, any sort of all-over ablution, was little known before 1840. A man rose in his ultra-stuffy bedroom, suffering, it might be, from the "fun" of last night's punch, and experienced no glow from the morning bath. He breakfasted and dined too heavily, supped too late, was booted and riding on vile roads in all weathers for very many hours, played cards at night in close air, drank much incidentally, slept a very short series of hours, and died with worn-out arteries at a time when middle-age now begins. But he often laughed uproariously, and the open air was good for him, as Mr. Blaker points out. There is another side, however, to the picture. The Early Victorian medical man was often a pioneer in his own district of sanitary reform, though he may have set a poor example to his patients in matters of personal health. Ruining his own health by drinking that of others, he nevertheless often ruined his own private practice, unconsciously but honourably, by promoting public health, especially by the new methods of water-supply which came into vogue and honourably distinguished the history of

boroughs and rural districts under Queen Victoria. In the series of 2000 medical men to which we have already referred a very large proportion were sanitarian reformers in their own districts.

THE METROPOLITAN WATER-SUPPLY DURING JANUARY, FEBRUARY, AND MARCH, 1920.

With a slightly increased rainfall in January, 1920, compared with the average of the previous 37 years, there were variations in the quality of the raw water and drinking supplies from the different sources. The results of the chemical examination showed that the Thames raw water improved in quality, while that of the Lee deteriorated. The New River raw water gave a good chemical return, but with turbidity and bad colour. The filtered waters showed, generally speaking, a fall in chemical quality, but they were satisfactory from the bacteriological standpoint. February was a comparatively dry month, and the results of chemical examination indicated the Thames, Lee, and New River raw waters to be improved in quality, and the same results are reported in the case of the filtered waters. Compared with the year 1919 the Thames raw water proved to contain more, and the Lee and New River waters fewer, bacteria. The filtered waters were, however, satisfactory. The month of March showed a normal rainfall, and the chemical purity of the raw waters was maintained. The filtered waters also gave good results on chemical examination, and the raw waters of all three rivers contained fewer bacteria than the corresponding month in 1919; the bacteriological examinations of the filtered waters followed suit.

ROYAL ARMY VETERINARY CORPS.

It appears from a recent reply to a question in the House of Commons that the post-war establishment of the Royal Army Veterinary Corps has not yet been finally settled. On a pre-war basis the establishment, including India, is 1 major-general, 6 colonels, 6 lieutenant-colonels, and 156 majors, captains, and lieutenants. The last three ranks are grouped under one head as promotion to the rank of major is by length of service. There are at present 3 major-generals, two of whom are holding colonels' appointments and are included in the establishment of colonels, on which there is no deficiency or surplus. There is a surplus of 2 in the rank of lieutenant-colonel. Two lieutenant-colonels hold the acting rank of colonel and 3 majors hold the acting rank of lieutenant-colonel owing to the temporary continuance of colonels' and lieutenant-colonels' appointments in excess of the normal requirements. Allowing for a recent increase of establishment of 30 in India, there is a total deficiency of 11 in the establishment of regular officers of the corps, which is met by the employment of Special Reserve, Territorial Force, and temporary officers. All officers are paid at the rates laid down for their rank with the exception of the major-general holding a colonel's appointment in England, who is paid as a colonel. Since April, 1918, 2 lieutenant-colonels, 7 majors, and 8 captains have voluntarily retired, and no further retirements are at present under consideration.

FLOUR AS CATTLE FOOD.

The Ministry of Food denies that there has been any increase in recent years in the number of firms mixing with cattle food flour purporting to be damaged and unfit for human food, nor is there reason to believe that any proportion of flour which is condemned as unfit for human food would be suitable for bread or for like purposes. The enforcement inspectors of the Ministry are constantly engaged in making investigations with a view to detection of offences against the orders relating to the use of flour for purposes other than human food.

A SHERRYGLASSFUL.

The following prescription was brought by a patient to the practitioner who has sent it on to us for our consideration:—

For Mr. P.

Mixture No. 1.

1920.

R. Quininae Sulphatis, grs. 80.
Acidi Sulph. dil. q.s.
Aquam, oz. 8.

Solve. Half a sherryglassful (2 tablespoonfuls or one-eighth of the bottleful) every day just before breakfast, without fail. The bottle to be refilled once a week for more weeks.

It was received by the sufferer from a specialist on a medical board. Our correspondent criticises the prescription severely from the point of view that it emanates from a specialist, but we take it that the special learning of the physician was rather displayed in making the diagnosis than in inventing the prescription. There can be no doubt that in many cases the treatment would be quite efficacious. One thing that has puzzled our correspondent in this prescription is "how the specialist came to think of this measure—the sherryglassful"; but surely the connexion of the wineglass with prescribing is fairly old and originated at a time when the wineglass was uniform in capacity and constituted the eighth of a bottle. Since those days wineglasses have been enlarged, notably for champagne

and claret, and diminished for liqueurs, while for sherry the glass has remained more or less the same size; and by a coincidence sherry is the only recognised wine in the British Pharmacopœia. Our correspondent criticises the prescription severely for other reasons, in that it is not stated how often the bottle is to be refilled and is not signed or dated.

A PROPOSED FREE STATE MEDICAL SERVICE FOR SOUTH AFRICA.

IN the Union House of Assembly, Capetown, on June 29th, Mr. Hills, Labour Member for Springs (Witwatersrand), moved the appointment of a Select Committee to report upon the advisability of establishing a State medical service to provide free medical and hospital treatment. Mr. Hills pointed out the great increase in medical fees which made it almost impossible, he said, for people to avail themselves of medical assistance. On the other hand, there was the legal criminal responsibility incurred for not calling in medical aid. He referred to the great charge on the State which resulted from children growing up without the necessary medical treatment. The curing of the sick was a service inherent in any civilised community, and this was the principle underlying the motion.—Mr. Gow, in seconding the motion, said that he recognised the sacrifices made by the medical and nursing professions, which had done more for the sick than any other section of the community, but there was a large section of the community who could never afford to pay for a doctor or a nurse.

The Minister of Public Health, while agreeing with much that had been said, held that it would be practically impossible to carry out the principles of the motion. There were about 2500 doctors in the Union of South Africa, and their salaries would, he took it, average roughly about £1000 a year. The resolution therefore meant that the State would be called upon to bear an expenditure of £2,500,000 per annum, and, in addition, the cost of medicines and nurses. He feared, too, that if they tried to establish the principle proposed the medical men required would not be available. At the present time any person who was unable to pay was taken in free at all the State-aided hospitals, and he feared it would be difficult to go further just now. Government district surgeons also gave treatment and medicines free where necessary, and the Government was endeavouring to meet the needs of outlying districts.

Mr. Alexander (Unionist Member for Capetown) moved as an amendment to apply the motion to people unable to pay for treatment, or, alternatively, that a national insurance scheme be established to deal with cases of chronic invalidity or sickness. This amendment having been negatived by 51 votes to 43, the original motion was then defeated by 74 votes to 24.

INSANITY IN SCOTLAND.

THE sixth annual report of the General Board of Control for Scotland has just been issued, and shows that on Jan. 1st of this year there were 17,580 insane persons of whom the Board had official cognisance. The number included inmates of training schools for imbecile children who had not been certified under the Mental Deficiency Act, but was exclusive of insane persons maintained at home. Consideration of the total numbers of all certified patient shows that on Jan. 1st, 1916, there were 18,842 patients on the Board's register, as against 17,432 at the same date this year, being a decrease of 1410. The total number of patients admitted to establishments during 1919 was 3619. The admission-rate, which began to decline at the beginning of the war, appears to be resuming its usual rate of increase. The number of private patients discharged as recovered was 316, which is 66 more than in the previous year, while 955 paupers recovered—an increase of 145. The death-rate was 12.1, as against 14.6, the decrease being mainly due to the absence of epidemic diseases. The cost of maintaining pauper patients in asylums works out at 14s. 7d. per week, in licensed wards of poorhouses 13s. 8d., and in private dwellings 9s. 7d. It is recorded with satisfaction that the limitation to £20,000 of the Government grant to local authorities has been removed by an amending Act, and that henceforth one-half of the costs of maintenance will be paid from Imperial funds.

In the Hospital for July 24th Mr. Gilbert G. Panter, secretary of the Great Northern Hospital, outlines a scheme of voluntary insurance for the purpose of providing a stable income for voluntary hospitals. The suggested insurance might serve to meet the demand on the part of workers for a definite guarantee of tangible benefits in exchange for their contributions.

Veritas has failed to substantiate his information by adding his name and address. There is nothing to prevent persons not on the Medical Register from giving so-called medical service. What they are not allowed to do is to represent that they possess medical qualifications.

Mr. W. R. N. does not describe what his practice is or give any detailed information concerning his patients. The matter is one that might be reported to the medical officer of health. It is quite outside the sphere of the General Medical Council.

Horace Nobell Lecture

ON

BACTERIAL INTOXICATION.

Delivered before the Royal College of Physicians of London.

By F. H. TEALE, B.Sc., M.D. LOND., F.R.C.P. LOND.,

LECTURER ON BACTERIOLOGY, UNIVERSITY COLLEGE HOSPITAL MEDICAL SCHOOL, AND HONORARY MEDICAL OFFICER IN CHARGE OF THE VACCINE DEPARTMENT, UNIVERSITY COLLEGE HOSPITAL.

MR. PRESIDENT AND GENTLEMEN,—In this lecture I propose to deal with some recent experiments on bacterial intoxication, dividing my observations into two parts: I. Those dealing with the bacteria themselves. II. Those dealing with the infected animals.

I. OBSERVATIONS ON THE BACTERIA THEMSELVES.

(a) "Washed Spores" and Latency of Infection and Intoxication.

It has become an accepted fact in text-books that the spores of bacteria carefully freed from their toxin do not germinate when inoculated into a susceptible animal. Their fate is variously described according to the result to be explained. Thus it is found that lactic acid inoculated simultaneously with the washed spores causes infection to take place with typical intoxication. This is explained by saying that lactic acid prevents phagocytosis of the spores, and thus their destruction is inhibited and germination followed by toxin formation is allowed to occur. Again, the injection of lactic acid, quinine, &c., may cause infection and toxin formation to occur days and even weeks after the inoculation of the spores. Here the idea is that the spores have remained latent either at the seat of inoculation or in the other tissues, and that the lactic acid by causing destruction of tissue produces a suitable medium for the germination of the spores.

The original work on the persistence of the washed spore in its latent state after inoculation was published by Tarozzi and confirmed and extended by Carforna. Their work, however, is valueless from the point of view of latency of the spore, because nowhere in their experiments has any attempt been made to differentiate between germinated forms and spores. It was taken for granted that the growths developing from the culture of the infected tissues must be from latent spores. Koser and McClelland subsequently investigated the same subject, but did not really determine if any of the spores became vegetative forms. They only showed that the washed spores of aerobic organisms rapidly disappeared both from the seat of inoculation and the internal organs, and that the washed spores of the obligatory anaerobes survived for some time. They made no effort to ascertain if in the case of the aerobic bacteria the disappearance of the spores could be accounted for by their germination into vegetative forms, and if the same did not occur to a lesser extent with those from the obligatory anaerobes.

Dr. E. Bach and myself investigated this problem some time ago with a view of studying the reason of the latency of the symptoms of intoxication following injection of these washed spores.

We experimented with carefully washed spores obtained by subjecting well-spored cultures to 80° C. moist heat for three hours. These spores from both types of organisms were inoculated by various routes into susceptible animals, and at intervals the organs of these animals were taken sterilely, emulsified, and cultures made from these emulsions: (a) From the emulsions direct, to obtain the total number of bacteria present either as spores, vegetative forms, or both. (b) After heating the emulsion to 80° C. for 30 minutes, to obtain the number of spores present, and by comparison with the results of (a) to get the number of vegetative forms. In addition the washed spores were inoculated intravenously into rabbits and the rate of disappearance from the peripheral circulation noted. Thus, a rabbit of 2020 g. was inoculated in the vein of one ear with $\frac{1}{2}$ c.cm. of a very thick emulsion of washed anthrax spores. Cultures were made from the blood from the opposite ear vein at intervals, and the result was as follows.

No. 5058

Directly after inoculation there were 50,000 spores per c.cm.

5 minutes	"	"	10,000	"	"
10 "	"	"	2,000	"	"
15 "	"	"	800	"	"
30 "	"	"	800	"	"
60 "	"	"	400	"	"
2 hours	"	"	100	"	"
3 "	"	"	nil	"	"
5 "	"	"	nil	"	"

Experiments performed on guinea-pigs inoculated with washed spores and killed at different intervals show that the removal of the spores from the peripheral circulation is due to phagocytosis occurring especially in the capillaries of the liver, spleen, and lungs. The mechanism is that the spores, like the vegetative forms of bacteria, act as foreign bodies, cause a process of beginning clot formation in the capillaries of the above-mentioned organs, and get entangled in the small masses of clot thus produced. The leucocytes are attracted to these masses of bacteria-containing clots and the bacteria become phagocytized. Intraperitoneal injection shows a similar process of phagocytosis by the endothelial cells of the omentum, and later by the polymorphonuclear leucocytes, just as for vegetative bacteria. With subcutaneous inoculation numbers of spores are phagocytized, but a relatively large number remain free for a long time. This is not peculiar to the spores; ordinary vegetative bacteria are found to remain free for quite long periods in the subcutaneous tissues.

These results show that the washed spores on injection into an animal are treated just like ordinary vegetative forms of bacteria, as regards phagocytosis, &c. The following experiments will show what happens later to the injected spores.

Experimental Results.

1. Constant amounts of carefully washed spores of *B. anthracis* were inoculated intravenously into a series of guinea-pigs. The animals were kept alive for various periods and emulsions were made from the spleen and plated.

	Emulsion unheated.	Emulsion heated to 80° C. for 30 minutes = latent spores.
1 day after inoculation	1,200,000	Nil.
2 days "	800,000	"
3 "	350,000	"
5 "	80,000	"
7 "	10,000	"
14 "	7,000	"

2. *B. oedematis maligni*, washed spores, also inoculated intravenously into guinea-pigs, spleens plated.

	Emulsion unheated.	Emulsion heated to 80° C. for 30 minutes.
1 day after inoculation	860,000	24,000
2 days "	180,000	2,600
4 "	80,000	1,400
10 "	2,000	20

These experiments show that the spores of aerobic and obligatory anaerobic bacteria germinate when inoculated into a susceptible animal, and this in spite of the phagocytosis which goes on directly after their inoculation. The spores of the aerobic organisms germinate more completely and rapidly than those of the anaerobes; also the spores appear to persist in the subcutaneous tissues at the seat of inoculation longer than in the internal organs. The question then arises as to what happens: the phagocytized spores apparently are not all killed, a large number germinate. Sections made from the internal organs of an animal inoculated some days previously with washed spores show that there are free vegetative forms in large numbers in the capillaries, of the liver, &c., not in the wandering nor apparently in the endothelial phagocytes. Smears made from the peritoneal cavity and omentum two days after the inoculation of washed spores of *B. anthracis* show 90 per cent. spores phagocytized, 10 per cent. free, 70 per cent. bacteria are free, 30 per cent. phagocytized; and five days after inoculation show that 97 per cent. of the spores are phagocytized and 3 per cent. free, and that of the vegetative forms 60 per cent. are phagocytized and 40 per cent. free. The spores form 60 per cent. of the total forms, the vegetative 40 per cent.

The examinations of the smears from the peritoneum after inoculation into that cavity, taken in conjunction with the cultural counts, show that a large number of the spores have been killed. Hence we must come to the conclusion that when washed spores are inoculated into a susceptible animal large numbers are destroyed, but quite large numbers germinate and these forms become only slowly phagocytized and destroyed, and that in spite of the presence of large numbers of these germinated vegetative forms in the animal it exhibits no signs of poisoning. The germinated vegetative forms are incapable of provoking intoxication.

F

These experiments further show that the germinated forms do not appear to multiply but become relatively slowly destroyed. Hence they must be able to derive sufficient food from the infected host to enable them to survive for some time, and, on the other hand, to be so little irritative or foreign that they are not rapidly phagocytosed or destroyed in the plasma or phagocyte. It becomes evident, therefore, that these vegetative forms from washed spores (1) do not secrete a toxic substance (tetanus bacillus, *B. welchii*), or (2) are so slowly disintegrated that any possible preformed endotoxin is liberated in such small quantities at a time that it has no apparent effect on the infected animal. It cannot be argued that the washed spores have been so affected by the preliminary treatment that they give rise to avirulent vegetative forms, which only become virulent as the result of future accidents—e.g., injection of lactic acid, &c. This can be shown not to be the case, since if inoculated intraperitoneally with some 30 per cent. gelatine or sterile blood charcoal, typical infection occurs with these spores.

It has long been known that simultaneous inoculation of lactic acid, quinine, other organisms or trauma will cause fatal infection to occur from these washed spores. The injection or trauma need not be simultaneous with the spore inoculation, they may occur days after.

Influence of Secondary Factors in Toxicity.

The question is, how do these secondary factors affect the toxicity of the vegetative forms arising from the washed spores? Metchnikoff stated that lactic acid acted as a negative chemiotactic agent, and that when inoculated with the washed spores it inhibited their phagocytosis and hence their destruction, and thus allowed germination to occur with fatally resulting infection. He adduced as further proof of this the experiment of placing the washed spores in bags of filter paper, and introducing these into the tissues. He argued that the filter-paper capsule prevented the phagocytes from getting into contact with the spores, so germination was not impeded and the vegetative forms thus produced caused infection in the ordinary way.

Our experiments, however, completely negative these suggestions. In the first place, lactic acid does not act as a negative chemiotactic agent (at any rate in the early stages of phagocytosis); and, secondly, the injection of lactic acid will produce the same result when made days after the spore inoculation. In this case it cannot be claimed that the lactic acid interferes with an already accomplished phagocytosis. Further, a fatal result may be produced by the simultaneous inoculation of sterile blood charcoal with the spores—here there can be no question of the charcoal interfering with phagocytosis.

How, then, does the lactic acid act? It does not interfere with phagocytosis in the early stages, and later, even if it did, this factor alone would not alter the condition of things, since the germinated forms are largely free, as seen from the microscopic evidence already adduced. Lactic acid when injected will cause the lowering of the antitryptic titre of the plasma, and 0.5 c.cm. of $N_{1/1}$ lactic acid inoculated into a guinea-pig of 250–300 g. ought to produce a considerable fall, since 5 c.cm. $N_{1/1}$ lactic acid inoculated intravenously causes the antitryptic titre in a rabbit of 2000 g. to fall to 30 per cent. It is known that 0.5 c.cm. of $N_{1/1}$ lactic acid usually provokes a fatal result in guinea-pigs previously inoculated with washed spores. It might be thought that the destruction of antitrypsin by the lactic acid allows of autolytic digestion of the blood plasma, so that the bacteria would find a sufficiency of easily assimilable food and so start multiplying vigorously, and thus bring about a fatal issue. At first sight this might be supposed to be the explanation, since the intraperitoneal injection of gelatine into an animal inoculated shortly before with washed spores will produce a like result, the gelatine acting as the suitable nutrient medium in vivo. On closer and further examination this cannot be maintained, since subsequent injection of peptone does not produce a like result, and, more important still, the lactic acid does not produce a multiplication of the bacteria. In the case of the experiment with the washed spores of *B. anthracis*, the subsequent injection of lactic acid will produce a fatal result 14–21 days after the inoculation of the spores, but the post-mortem appearances are not at all typical of anthrax infection; the spleen is small and pale, the blood and the various tissues are not crowded with bacilli; in fact, the tissues appear microscopically free from the anthrax bacillus, and culturally the blood and tissues give no greater growths than controls which had no lactic acid.

Then, again, lactic acid may act by causing damage to the tissues at the seat of its inoculation and autolytic degradation of the affected tissue; forming a nidus for the further development of bacteria locally and supplying digestive products for the others. As far as local damage is concerned, the injection of Gram's solution of iodine does not produce a fatal result in these cases, although in some cases the mere production of a wound or stirring up a wound will produce a lighting up in the human subject—but here it is not damage far away from, but at the seat of original infection, and the direct influence of mechanical irritation, &c., on the bacteria must be taken into account. Lactic acid might also conceivably act in a general way in the tissues, lowering their resistance and so allowing the bacteria to multiply and produce toxic substances. The injection of lactic acid diminishes the buffer salts, and so may hinder the removal of CO_2 from the tissues, but against this mode of action is the fact that sodium carbonate can cause a fatal result in animals inoculated with washed spores. These conjectures are, on the whole, very unsatisfactory—the best explanation is that the action of the chemical, drug, &c., is a direct one on both the tissues and bacteria, altering the existing mutual equilibrium of the environment of the one to the other.

Habituation to Environment of Bacteria Born in Captivity.

It would appear from the experimental evidence that bacteria born in the tissues from washed spores have become habituated to their environment, are able to carry on their vital functions, except multiplication, and do not act as irritants to the tissue, and consequently only become slowly phagocytosed and destroyed. The injection of acids, alkalies, drugs, &c., affects the relative condition of habituation—the balance is disturbed and, as we shall presently see, interactions take place, producing toxic substances. In the case of the tetanus bacillus this alteration leads to the secretion of the exotoxin.

These observations show that: (i.) Washed spores do not all remain "latent." (ii.) The germinated forms do not give rise to the formation of toxic substances, this being due to either (a) the slow liberation of the toxalbumin because of the slow disintegration; (b) the habituation of these germinated forms to the physical conditions of the tissues and vice versa, disturbance of this leading to interaction, alteration of surface tension, &c., and toxin formation.

(b) Evidence from the Treatment of Bacterial Protein in Various Ways.

These may be summarised as follows:—

1. The intimate disintegration of the bacterial protein by grinding alone or grinding at very low temperature. These methods produce a very finely divided bacterial substance, which, as the result of the division, has become correspondingly increased toxicity. This increase in toxicity is only carried to a certain degree; the so-called endotoxin thus produced never causes a sudden death, such as would occur with greatly increased doses of the alkaloids—e.g., strychnine, there is always a latent period of several hours. Then, again, the endotoxins obtained in this way from the different bacteria have no distinctive characteristic such as one would expect if there were specific endotoxins in the different varieties of bacteria; they all give rise to signs of intense poisoning without any characteristic symptoms. This method of pulverisation may be supposed to act in one or both of two ways. (1) Rendering available for immediate use and rapid action of a possible preformed toxalbumen or toxalbumose, which would be non-specific, simply that the albumin is primarily toxic; like protamine is among the ordinary animal proteins. (2) The fine state of pulverisation of the bacterial protoplasm exposes for a given amount of bacteria an infinitely greater surface for interaction with the antibodies in the tissues and tissue fluids, hence the interaction becomes more rapid, more intense, and a consequent greater and more rapid accumulation of the products of interaction occurs, which as we shall see later, probably produce the toxic effects.

2. *Maceration of the bacteria.*—Here the bacteria are allowed to undergo varying degrees of autolytic degradation and maceration, so that in addition to the greatly increased fineness of division of the bacterial protein, acting in the way already discussed, proteose bodies are also formed which produce the type of acute or delayed anaphylactic death. By carefully timing the duration of and hence the degree of maceration, &c., an acutely toxic suspension can be obtained, producing "anaphylactic" phenomena.

3. *Hydrolytic cleavage by alkalies, &c.*—Here the process is not the liberation of a preformed toxic substance, but the formation of hydrolytic cleavage bodies which can be acutely toxic. By none of these methods, therefore, can specific endotoxins be demonstrated.

II. OBSERVATIONS FROM THE SYMPTOMATOLOGY OF BACTERIAL INFECTION OF ANIMALS.

The Post-mortem Appearances, the Toxicity, and Chemical Changes in the Tissues.

Vaughan and Wheeler, and Teale and Embleton independently drew attention to the uniformity of the symptoms of fatal bacterial infection in animals of the same species. In the main these can be summarised as follows:—

After the initial symptoms of invasion the signs of the intoxication are: 1. Gradually falling temperature, so that the animal dies with a temperature of 94° F. or less. 2. Gradually increasing paresis spreading from the posterior to the anterior extremities. 3. Convulsive seizures and respiratory disturbances. In rabbits these convulsive seizures are very marked, the animal getting laboured, then spasmodic respirations, then frequently a loud cry and a convulsive seizure, with rapid death. 4. Post mortem, right-sided distension, diminished coagulability of the blood, accumulation of blood fluids in the tissues, and in guinea-pigs distension of the lungs.

A. Vaughan and Wheeler thought that the antibodies in the tissues acted upon the bacterial protein and liberated by a process of cleavage a preformed toxic substance, and that although in the main the action of the toxic substance from different sources was very similar, there were some individual differences. Vaughan maintains that the toxic substances he obtains by treating various proteins with alcoholic potash are not products of hydrolysis of the protein, but are pre-existent and merely split off from combination with other protein constituents, these together forming a non-toxic combination. It is very peculiar that such drastic treatment as boiling with alcoholic potash should only split off this preformed toxic substance and cause such disintegration of the rest of the protein as to produce a large amount of ammonium.

B. Then Jobling, Petersen, and other workers were similarly impressed by the uniformity of the symptoms of bacterial poisoning in animals of the same species. These observers thought that the symptoms are all due to proteose poisoning, but that the proteose is not derived from the digestion of the bacteria by the antibodies and complement acting as a proteolytic ferment, but that the proteose is formed from the animal's plasma. The bacteria, according to this theory, produce proteose intoxication by causing the adsorption of the plasma antitrypsin. This adsorption allows the plasma proteolytic ferment to auto-digest the plasma, and thus form toxic proteoses. Their idea is therefore that bacterial intoxication is due to varying degrees of peptone poisoning from the infected host's own plasma, and so bears a close relation to anaphylaxis, which they also explain as the result of proteose poisoning due to an autolytic degradation of the plasma brought about by the antigen adsorbing the antitrypsin and thus activating the plasma ferments. They also explain the formation of anaphylotoxin from bacteria in vitro by a similar theory, and then appear to bring into line some peculiarities which have been very puzzling—viz., why anaphylotoxin can be produced by exposing serum to non-bacterial substances, such as starch, agar, &c. Here, again, the idea is that bacteria, starch, &c., cause adsorption of the serum antitrypsin—this allows auto-digestion of the serum to take place with consequent formation of toxic proteoses. According to these observers, the antitryptic power resides in the unsaturated lipoids of the serum, and removal of these by solvents or adsorbents allows the proteolytic ferments of the serum to become active.

Dr. Bach and I also investigated the question of the relation of antitrypsin to infection, anaphylaxis, &c., but our results unfortunately do not agree with those of Jobling and his co-workers. Our experiments show:—

(i.) That the antitryptic power of a serum does not reside in the unsaturated lipoids. All the fats can be completely removed by Cathcart's method without affecting the antitryptic power of the serum. Further, we have been able to show that the antitrypsin of egg albumin is protein in nature, having been able to isolate it in a fairly pure state. (ii.) That the antitrypsin of the serum is not adsorbed in vitro by bacteria or by indifferent substances like agar, starch, &c., either at 0° C. or 37° C. (iii.) That after exposure to agar, starch, or dead bacteria, a serum becomes intensely toxic without any alteration in the antitryptic titre of that serum and without any chemical evidence of auto-digestion or digestion of the bacteria. (All these experiments had to be carried out with hæmoglobin free serum and with absolute bacterial sterility. For the latter reason diffusion methods were not used.) (iv.) That a weak proteolytic autolytic ferment exists in the serum of the guinea-pig, and a weaker one in the rabbit and man. The ferment can be demonstrated after destruction of the

antitrypsin by chloroform in the cold, subsequent complete removal of the reagent by evaporation in vacuo followed by incubation at 37° C. A serum thus treated does not cause acute anaphylactic death—i.e., proteose poisoning. Jobling claims to have produced an intensely toxic serum by removing the antitrypsin by chloroform at 37° C., incubating and removing the chloroform by centrifugalisation and filtration. This does not remove the chloroform, and the acute death following intravenous injection of the serum treated in this way is due to chloroform. Chloroform at 37° C. also destroys the proteolytic ferment.

These experiments carried out by Dr. Bach and myself show that the substances which provoke the formation of anaphylotoxin in vitro do not do so by adsorbing antitrypsin, hence auto-digestion of the serum in the sense of the formation of toxic proteoses from it cannot occur, and we have to look for another explanation of the toxicity of a serum which has been thus exposed. Jobling further claims that by the intravenous injection of agar, kaolin, colloidal silicic acid, acute anaphylactic death can be produced. The theory being that these substances cause adsorption in vivo of the plasma antitrypsin which is rapidly followed by auto-digestion of the plasma.

Anaphylaxis.

Various observers use the term anaphylaxis very loosely, and it is very much to be deprecated; it gives a completely erroneous view of true anaphylaxis. The term should not be used simply for sudden death with convulsions, &c. In a great many cases where death is simply due to intravascular clotting the symptoms are very much like those of anaphylaxis; to this class belong the experiments of Jobling with agar, &c. These cases should not be called anaphylactic; they can easily be distinguished by the fact that, apart from post-mortem appearances, the preceding or simultaneous injection of an anti-coagulant like leech extract prevents a fatal issue, but does not do so with true anaphylactic shock; examples of this are the sudden death from intravascular clotting after intravenous injection of agar, silicic acid, carmine, muscle extract, &c. This theory of Jobling's further postulates that anaphylaxis is a blood reaction, which we now have reason to believe it is not. Jobling and his co-workers have therefore failed to establish the main points of their theory. In connexion with this Dr. Bach and I investigated the changes in the blood, tissues, and effusions in infected and in sensitised animals.

(a) Antitryptic Content of the Blood in Infection.

As the result of the inoculation of any form of protein, whether bacterial or otherwise, there is an alteration in the antitryptic content of the blood. The variation is fairly uniform with all forms of infection. There is at first a negative phase, beginning soon after the inoculation and reaching its maximum about 2-4 hours after the infection; this is followed by a return to normal in from 8-24 hours, and the rise is continued so that the antitryptic titre may reach 150-200 per cent. of the original. This usually lasts for 2-3 days and is followed by a gradual return to normal. The question then arises as to the meaning of this fall in the antitryptic titre and its relationship to infection and intoxication. In the first place, the animal infected may die with the antitryptic titre in any phase—negative in the first 2-4 hours, rising up to 18-24 hours, and even high above normal, 150-200 per cent., two or three days after infection. Even when acute deaths occur in 2-4 hours the titre has only fallen about 20 per cent. in the majority of cases. On the other hand, we have observations where the animal has recovered with a low antitryptic titre. Taking it as a whole, the antitryptic titre at the time of death depends on the duration of the infection. At first sight it would appear that the antitrypsin had become adsorbed by the infecting material, and consequently autodigestion of the plasma and the production of toxic proteoses might have occurred. It must be noted that the fall in the antitryptic content is only small and the presence of the remaining 80 per cent. means that the serum is not only capable of inhibiting any proteolytic enzyme in the serum but also added trypsin; hence, unless we postulate great local reductions sufficient to allow autolysis to go on in these local areas, the loss of antitrypsin as a whole will not be sufficient to allow of auto-degradation. The great objection to this antitrypsin loss accounting for bacterial intoxication by the possible production of proteoses by autodigestion of the plasma is given by the following experiment with lactic acid.

A rabbit of 2000 g. was inoculated intravenously with 5 c.cm. of N₁ lactic acid, and the antitryptic titre fell in 15 minutes to

66 per cent., in 30 minutes to 50 per cent., in 2 hours to 40 per cent., in 3 hours to 30 per cent., and remained so for 19 hours, then rose to normal in 30 hours after the inoculation. Here, in spite of the rapid and great fall of the antitryptic titre, the animal within 30 minutes of the injection was perfectly well and continued to be so. If, therefore, the destruction or adsorption of antitrypsin *in vivo* leads to a certain degree of autodigestion of the plasma, then with the lactic acid injection experiment, which almost completely destroys the antitryptic titre, a very violent proteose poisoning should occur, but there is absolutely no sign of poisoning in the remotest degree. Again, if the poisoning in infection were purely a proteose poisoning, resulting from autodigestion of the plasma following antitrypsin adsorption by the bacteria, it should follow that the rise in antitryptic titre to above normal should indicate a complete cessation of the activity of the autolytic ferment and a cessation of formation of toxic proteoses. If, however, it should still be held that the poisoning following bacterial infection is an autoprotoese intoxication brought about as mentioned above, then with the rise in antitrypsin and cessation of poison formation there must be added another factor—viz., that the toxic proteoses may cause changes in the tissue cells, which continue after the proteose formation has ceased, and so lead to a fatal result. Again, there is also no difference in the type of antitryptic curve obtained in animals after injection with pathogenic or non-pathogenic bacteria, and therefore in both autodigestion of the host's blood plasma should occur equally. This is another argument against the theory of autodigestion intoxication in bacterial infection. The question, then, is what does the alteration in antitryptic content of the blood indicate? There seem to be two further possibilities to be considered. 1. That the fall in the early stages of infection is due to antitrypsin neutralising ferments liberated by the destruction of leucocytes. Against this, however, is the fact that the antitryptic titre rises as a fatal infection progresses. During this the liberation of leucocytic ferments due to continuing phagolysis ought to lead to a progressive diminution of the antitrypsin unless the initial loss is rapidly made up and ends by over-production. Another point against this is that the negative phase may be absent even with a fatal infection, on the one hand, and does occur when absolutely non-toxic substances, such as egg albumen or even cod-liver oil, are inoculated extraperitoneally. 2. That the antitrypsin influences tissue metabolism. This will be discussed later.

(b) *The Relationship of Antitryptic Titre to Anaphylaxis.*

I have already drawn attention to experiments which show that a highly toxic anaphylotoxin can be made without any evidence of antitryptic adsorption or autodigestion. I shall now state the results of our experiments in anaphylaxis.

In absolutely acute anaphylactic shock there is no loss of antitrypsin in the blood, in delayed shock there is a gradual loss, the loss varying directly with the prolongation of the symptoms leading to the death of the animal. In cases where there are severe symptoms followed by recovery the antitryptic curve is just like that during infection with bacteria. The fall in the subacute and delayed anaphylactic shocks may amount to 20 per cent., and is not much if at all greater than the fall due to the primary injection of the antigen in a normal animal. In acute anaphylactic shock, therefore, there can be no fulminating or rapid autodigestion of the serum, since there is no antitrypsin adsorption accompanying the combination of antigen with its specific antibody.

In the delayed shock the fall is not greater than with the primary antigen injection; hence, if the shock were solely due to proteose intoxication following antitrypsin adsorption, it should be as great with the primary as with the second inoculation of antigen. Again, the experiments dealing with lactic acid injection must be borne in mind, here the fall in the antitryptic content is sudden and intense, yet there are no signs of acute proteose poisoning. It might be argued that the lactic acid destroys the ferment at the same time, and hence autodigestion does not occur. This is undoubtedly true in *in vitro* experiments, but, as Professor Baylis shows, there is no increase of H-ion concentration in the plasma even with the injection of such large amounts of acid as used in the experiment; hence the destruction of the ferment should not take place.

(c) *Chemical Changes: Non-Coagulable Nitrogen.*

Finally, Dr. Bach and I investigated the non-coagulable nitrogen in the blood during infection. During infection the animal takes no food, and in a normal animal during starvation the N.C.N. gradually falls. We have found that there is no demonstrable rise in non-coagulable nitrogen in the blood of the animal dying 1-4 hours after the infection, and none in acute or delayed anaphylactic shock, but as the period of infection is prolonged there is a corresponding increase in N.C.N. Dr. Bach and I have shown

this is practically solely due to an accumulation of urea in the blood. There is very little evidence of the accumulation of amino-acid nitrogen in the blood during infection, and our methods are not delicate enough to demonstrate small quantities of proteoses. This increase in urea points to greatly increased tissue katabolism, and it appeared probable that the increase in antitrypsin might be accounted for as an effort to control this, to inhibit the intracellular proteolytic ferments. We accordingly performed experiments re the action of antitrypsin on tissue autolysis, and found that it had none, that serum only inhibited autolysis or slowed it down in so far as it diminished the amount of free acid available for the activation of the autolytic ferment. The activity of the autolytic ferment of the tissues is within limits proportional to the degree of acidity. Further, prepared antitrypsin from egg white had no influence on the autolytic ferments of fowls' organs.

Bacterial Poisoning the Result of Toxins Produced by Digestion of Bacteria.

C. The next point to be discussed is one which is older in date of conception—viz., the question of bacterial poisoning being due to digestion of the bacteria by the complement or complement and antibody, and according to the rate of accumulation of toxic proteoses from the digested bacteria symptoms occur. This conception was advanced some years ago by Dr. Embleton and myself. I want now to discuss this in the light of further knowledge and amend it. The idea of anaphylotoxin being the result of the proteolytic degradation of the antigen by means of its specific antibody and complement acting as the proteolytic enzyme is in the first place due to Friedberger. His work was apparently confirmed by Abderhalden in his demonstration of protective ferments. Now in all the methods used for demonstrating proteoses and digestive products in connexion with this work, Abderhalden and other workers did not carry out their experiments with absolute bacteriological sterility—and, in fact, with diffusion thimbles this is impossible. Dr. Bach and I carried out numerous experiments with scrupulous care with regard to bacteriological sterility to see if complement and specific antibody did act as a proteolytic enzyme on the homologous antigen; we were absolutely unable to find any trace of amino-acid nitrogen in these experiments, even when the experiment was carried on for days. Similarly we always got negative results with the Abderhalden test for pregnancy when carried out with complete bacteriological precautions. So from the direct chemical point of view we were unable to prove the proteolytic activity of complement and specific antibody.

There is, therefore, no direct proof in support of the theory that bacterial poisoning is due to the proteolytic degradation of the bacterial protein. There is only *a priori* evidence that proteoses can produce many of the symptoms of intoxication. Before discussing this matter further from this point of view, it will be advantageous to see if any evidence that toxic material can be demonstrated in the blood or effusions of animals dying from bacterial infection or anaphylaxis.

(1) With regard to the blood in infection. The great difficulty lies in the primary toxicity of the blood, especially if it has been whipped. Experimental evidence shows that the blood from an animal dying from bacterial infection is only slightly more toxic than that from a normal animal of the same species. The blood from animals dying from acute or delayed anaphylaxis is the same. The toxicity of the blood manifests itself on intravenous injection in the guinea-pig by causing the anaphylactic syndrome. (2) In effusions. There is no doubt that the effusions of animals dying from bacterial infection are highly toxic, so that doses of 2-3 c.cm. will cause acute anaphylactic death in normal guinea-pigs on intravenous inoculation. In these Dr. Bach and I have never been able to find any evidence of digestive products by methods other than diffusion methods.

The fact therefore emerges that "anaphylotoxin" can be demonstrated definitely in the effusions of infected animals, its demonstration in the blood is not so evident.

Is there any other evidence of "anaphylactic" phenomena occurring during infection? The symptoms already mentioned as being the prominent ones in the course of bacterial infection are very like those of delayed and protracted anaphylaxis—viz., the fall of temperature, fall of blood pressure, gradually increasing paresis, the respiratory troubles and convulsions, and post mortem the incoagulability of the blood and right-sided distension with pulmonary emphysema. Further, during the course of an infection by suddenly increasing the amount of bacterial protein an infected animal may be made to die quite acutely with typical acute anaphy-

lactic shock. Thus a rabbit infected with *B. coli* may, two to four hours after the infection, be killed quite acutely by the intravenous inoculation of one or two slopes of *B. coli*, the symptoms being rapidly increasing difficulty in breathing, sudden cry, convulsions, and death, with rapid fall of temperature and delayed coagulability of the blood. We have thus the evidence of (a) the presence of anaphylotoxin in the effusions; (b) the similarity between the symptoms of infective poisoning and anaphylaxis; (c) acute anaphylactic death may be brought about by further injection of antigen into an infected animal.

Relation of Antibody to Specific Antigen in the Causation of Symptoms of Intoxication.

Before the discussion of the possible nature of anaphylotoxin and anaphylaxis and their relation to toxicity and infection, the relationship of the antibody to the specific antigen in the causation of the symptoms of intoxication calls for examination.

This was discussed by Dr. Embleton and myself some years ago when we brought forward evidence from numerous experiments to show that the toxicity of a bacterium depends on the relative balance of its specific antibody to it. By altering their relationship the toxicity of a bacterium may be enhanced or diminished, and bacteria which previously were non-pathogenic may be made to cause infection, intoxication, and death. The amount of evidence bearing on this is fairly large. Thus, in addition to our own experiments there are those of Duval, who showed that living leprosy bacilli were not pathogenic to monkeys, but after sensitising monkeys with dead leprosy bacilli an inoculation with living bacilli was followed by typical infection and intoxication. Next is the experiment of Twort with the myco-bacterium bovis. This organism is absolutely non-pathogenic for the rabbit, but after a preliminary sensitising inoculation with dead bacteria a second one with the living bacteria produces typical infection and death. Similarly, take the pathogenicity of the human type of tubercle bacillus in the rabbit. As is well known, the human type is practically non-pathogenic for this animal, and the animal is used for differentiating by the pathogenicity test between the bovine and human types of bacilli. Dr. Embleton and I have shown that if rabbits are first inoculated with a dose of dead tubercle bacilli of the human type, after which they appear quite normal, have no fever or wasting, and then with a very small dose of living human bacilli, the rabbits will die of acute miliary tuberculosis. This has since been confirmed by experiments carried on by C. Austrian in the Johns Hopkins Hospital. Finally, there is our similar experiment with *B. mycoides*. The only drawback of this experiment is that occasionally by educating a cold growing *B. mycoides* to grow at 37° C. it becomes directly pathogenic, producing very rapid intoxication. But sometimes this is not the case, and the culture growing at 37° C. is not primarily pathogenic, but after sensitising a guinea-pig with dead bacteria of the same kind an inoculation of the living organism, which has proved to be innocuous in much larger doses, produces infection of the type *B. anthracis*. In addition to these experiments where the pathogenicity—i.e., the capability of an organism to produce infection and intoxication—is apparently brought about by increasing the antibody activity against it, there is another experiment which directly shows that an increased amount of antibody may directly increase the toxicity of a bacterium. Rabbits of the same size, weight, age, breed, &c., were inoculated (a) with a non-lethal dose of living or dead typhoid bacilli. Complete recovery occurred. (b) With the same dose of bacilli as in (a), but previously exposed to a high titre agglutinating serum, so that complete saturation had occurred. The injection of the sensitised bacilli caused death. In this experiment there can be no question of anything else but the increase in the antibody activity against the typhoid bacilli induced by the preliminary sensitisation of the bacteria; this increased amount of antibody has given rise to such an increased formation of poison from the same amount of bacteria that a fatal result has occurred. In the other experiments there is, in addition, the possibility of the preliminary inoculation producing a negative phase, and the probability that the further inoculation during this period of lessened resistance from diminution in antibody activity induces a summation of effects, and hence a fatal result.

Against the idea that the result of the above experiments are due to the production of a negative phase by the first injection and persisting to the time of the second one are:—

1. The supposed long duration of the negative phase in these experiments ten days. 2. That it is questionable if a

negative phase ever occurs. Bull has lately not been able to demonstrate it after inoculating bacteria into animals possessing some degree of acquired immunity against them. Similarly the injection of red cells into an animal of another species is rapidly followed by the production of antibodies. 3. Experiments similar to the above do not give like results with other bacteria. Thus occasionally strains of *B. mycoides* are met with which are directly pathogenic in very small doses in a very short time—few hours. Now if a guinea-pig is inoculated with dead mycoides first and then later on, as in the above experiment, with living mycoides of the variety which is primarily pathogenic, the animal instead of dying, recovers. Here we have the animal recovering from a certainly fatal dose during a so-called negative phase. Hence we must conclude that the negative phase theory fails; that the fatal result is not due to an inoculation occurring whilst the animal is in the state of a "negative phase." If we next consider the large group of pathogenic bacteria, evidence has long since accumulated that by increasing the antibody activity against the various bacteria of this group a condition of increased resistance can be attained. Here, again, we have the intoxication due to bacterial infection affected by altering the antibody activity. Finally comes the group of bacteria to which the animal is very immune—i.e., the bacteria are non-pathogenic. This group cannot be made pathogenic—i.e., to produce the signs of intoxication if the immune animal is first of all inoculated with a large dose of dead bacteria and then with living ones of the same kind. The method of increasing the antibody does not increase the toxic formation, hence they are quite different from the first group; they again form a potent argument against infection in the first group, being due to inoculation during a negative phase. Here the relationship between antibody activity and antigen is such that when these bacteria are inoculated no toxic disturbance is produced by their interaction. There is further evidence from experiments in sensitised animals of the relation between the antibody activity and intoxication. If a series of guinea-pigs is inoculated with 20 c.mm. of a 10 per cent. sheep red cells suspension, on the thirteenth to fourteenth day the following results can be obtained on reinjection:—

	Result.
(1) Gp. reinoculated i.v. with 1 c.cm. of 10% sheep red cell suspension ...	Nil.
(2) " " " do. sensitised with 1 unit of amboceptor ...	Nil.
(3) " " " do. with 5 units of amboceptor ...	Nil.
(4) " " " do. with 25 units of amboceptor ...	Animal ill, rapid recovery.
(5) " " " do. 100 units amboceptor ...	Acute death.
(6) " " " do. 500 " " "	Do.

Here by increasing the amount of antibody acting in the tissue cell on the antigen a fatal result can be produced. The increase in the antibody does not act by increasing the lysis in the plasma, the antibody already there is sufficient to do so. In the second week of sensitisation the titre of the serum is as high as it is in the third week. Again, in partial desensitisations the effect of a small sublethal reinjection is to reduce the activity of the antibody as a whole, but acute shock can be still obtained after such partial desensitisation by injecting a very much larger dose of the homologous antigen than is necessary to cause the acute anaphylactic shock in a non-desensitised animal.

These experiments show the importance of the factor of the relationship between the balance of antibody activity and antigen in anaphylaxis.

Functions of Circulating and Tissue Antibodies.

I want now to consider the functions of the circulating and tissue antibodies. As the result of the experiments of Dr. Bach and myself it would appear (1) that the antibody-complement complex does not act as a proteolytic ferment as far as can be definitely ascertained by chemical means when the experiment is carried out with absolute sterility; (2) that the antibodies do not act as agglutinins or opsonins in vivo.

Dealing with bacteria inoculated into the circulation we have shown that they are not agglutinated in vivo by the natural or acquired antibodies. The bacteria are removed from the circulation by a process of clot formation occurring in the capillaries of the liver, spleen, and lungs, the bacteria acting as foreign particles, and then phagocytosis occurs. Even intensely pathogenic bacteria against which the animal has apparently no antibodies at all—e.g., the *B. dysenteriae* Shiga in the rabbit, are removed from the peripheral circulation as rapidly as those against which the animal has an agglutinin. Further, the presence of a powerful agglutinin in the serum of an animal in no way hurries on the removal of the bacteria from the circulation, the rate of removal of pneumo-bacilli or typhoid bacilli occurs as rapidly in the normal as in a highly immunised animal with

a very high agglutinating titre against these organisms. Similarly in the serous cavities and subcutaneous tissues the antibodies can be shown not to act as agglutinins or opsonins. The process of phagocytosis is purely a response to the presence of foreign particles. The antibodies do not appear to hurry the process of removal and phagocytosis of the bacteria in the initial stages of infection. There is definite evidence, however, that the antibodies act as lysins in the circulation. This can be demonstrated by experiment with rabbits sensitised against red corpuscles; reinjection with the homologous red cells is always accompanied by hæmoglobinæmia. Lysis also plays an important part in the anaphylactic shock. Although acute anaphylactic shock is essentially a cellular reaction the lysis of the red cells is an important preliminary, since without this the antigen is unable to get into the cells wherein the reaction occurs. The excised uterus of a guinea-pig sensitised to red cells will only react if the homologous red cells used for the reaction are hæmolyzed. Similarly in bacterial anaphylaxis reinoculation with the homologous whole bacteria does not bring about shock; only when a bacterial extract is used can acute shock be obtained. Comparing this with the ease with which acute shock occurs on reinjection of red cells in sensitised animals, it appears that lysis of bacteria must be relatively much slower. Dr. Bach and I have endeavoured to demonstrate the presence of lysed bacterial protein in the blood of infected animals by a complement-fixation test, but have failed to get any evidence of the presence of such lysed bacterial protein; it may be that it is rapidly taken up by the tissue cells. Zinsser and Parker claim, however, to have obtained positive results. The Pfeiffer phenomenon also shows that the antibodies cause lysis of bacteria in the serous cavities, and the same can be demonstrated in the subcutaneous tissues. Excess of antibodies, on the other hand, appears to prevent lysis of the homologous antigen. This is seen in the Neisser-Wechsberg phenomenon *in vitro*, and can be shown *in vivo* in highly immunised guinea-pigs. If some guinea-pigs are highly immunised against the cholera vibrio, reinjection of these vibrios into the peritoneal cavity is not followed by the ordinary Pfeiffer's reaction; the bacteria do not become motionless, nor swell out, nor break up into granules. This action only occurs in highly immunised animals, and has apparently no parallel in normal ones. The circulating antibodies would appear therefore to act chiefly by sensitising the bacteria (i.e., combining with them) before phagocytosis occurs, and then, owing to this, hurrying on the process of lysis and destruction in the phagocyte. In the serous cavities and subcutaneous tissues the same process of sensitisation occurs, but the rate of phagocytic removal is much slower. In the latter site the bacteria may remain free for quite long periods. Bacteria, either in the circulation or elsewhere, which have not been phagocytosed may undergo extracellular lysis, and thus also finely divided bacterial protein will be rendered available for interaction in the tissue cells. Now, antibodies do not exist as such in the tissues; they cannot be demonstrated as such even in the most immune animals, though there can be no doubt that those in the body fluids are derived from the tissue cell. Vice versa, antibodies injected into an animal during passive immunisation become absorbed by the tissues and undergo some change there, so that, though they can no longer be demonstrated as such, they confer hypersensitiveness on the tissues. The tissues of an immunised animal which as a whole is not hypersensitive—i.e., in the anaphylactic state—appear to react *in vitro* like those of one in that state. It would thus appear that the circulating antibody is protective, so that by combining with the inoculated antigen it prevents the acute anaphylactic shock or even delayed shock. Here, again, the protection is relative; a highly immune animal with a large amount of circulating antibody can practically always be killed by acute anaphylactic shock or delayed shock by increasing the dose of homologous antigen inoculated. This analysis shows: 1. That there is a great similarity between the symptoms of bacterial intoxication and protracted anaphylactic shock. Occasionally acute anaphylactic symptoms may occur in an infected animal. Frequently the final symptoms are very much like those of acute anaphylactic shock. 2. The presence of "anaphylotoxin" in the effusions of animals dying from bacterial infection. This "anaphylotoxin" is not due to autodigestion of the plasma, nor due to proteolytic digestion of the bacterium. 3. That as in sensitised animals so in infection, the occurrence of poisoning can be affected by altering the balance of the antibody activity to the antigen. This cannot be explained by the antibody producing simply more rapid lysis and so liberation of preformed endotoxin, since in the experiments with *B. lepre*, *B. mycobacterium bovis*, *B. tuberculosis* (human), &c., no rapid lysis occurs, the bacteria multiply and produce typical infection and not simply an intoxication.

Nature of Anaphylactic Shock.

The infection intoxication is more to be compared to protracted anaphylactic shock. Now, acute anaphy-

laxis is a tissue reaction. What is the nature of the protracted shock? Delayed anaphylactic shock occurs when the rate of entry of the reacting dose of antigen into the circulation and thence to the tissue-cells is slow—i.e., when the route is either the intraperitoneal or subcutaneous. Here the slow rate of entry allows partial and slow desensitisation of the activity of the cellular antibody to occur. The reaction between the first small dose of antigen and the antibody is relatively slight, partial desensitisation occurs, and as more antigen accumulates slowly in the cells this desensitisation gradually progresses, and thus the interaction and consequent toxic formation becomes less and less, and in this way the total toxic formation is not very great. In these cases the interaction producing the intoxication might be supposed to be largely or to some extent between the antigen and the circulating antibodies, the cellular antibody having become completely or greatly desensitised. But against this is the fact that after complete desensitisation intraperitoneal or even intravenous inoculation produce no toxic effects, and this is not due to complete loss of complement or antibody in the circulation. Hence delayed anaphylaxis is largely a cellular reaction, although the circulating antibody may play a part and some anaphylotoxin be produced in the serous cavities, &c.]

Contrast between Infection and Anaphylaxis.

How far can infection be compared to this? Can a state of hypersensitiveness be demonstrated in the tissues of an animal highly susceptible to a certain bacterium?

There appears to be no evidence in favour of this. Dr. Bach and I prepared an extract of highly virulent *B. coli*, and added some to the excised uterus and intestine of a normal guinea-pig suspended in a bath of aerated Locke's fluid without producing any reaction. The animal which is highly susceptible to a given bacterium need not necessarily have its tissues in a state of complete hypersensitiveness, so as to produce the typical anaphylactic reaction when its unstriated muscle tissues are exposed to the lysed bacterial protein, the tissues may have various degrees of hypersensitiveness. This can be demonstrated *in vivo* by the varying temperature reactions occurring on reinjection with the homologous antigen in animals which have been sensitised for different periods, and so have different amounts of antibodies according to the interval elapsing between the first injection and the reinjection.

Course of Events in Infection.

In infection the course of events is much as follows:

(1) The bacteria gain access usually to the tissues or serous cavities. Primary blood infection is rare. (2) In the tissues and serous cavities phagocytosis rapidly occurs; if the infection is small, then the phagocytosis may be almost complete, with bigger infections a certain number of the bacteria remain free for quite a long time. The bacteria phagocytosed may—

(a) Be killed with little or no toxin production; (b) be killed with marked toxin production leading to phagolysis with the liberation of the killed and lysed bacteria and the toxins formed during the intra-phagocytic reaction. (c) mostly survive, some lysed, marked toxin production may occur; phagolysis ensues with liberation of the whole bacteria, lysed bacterial protein, and the results of the interaction.

Those left unphagocytosed may be similarly affected in the tissue fluids. Here there will theoretically always be some "anaphylotoxin" production as the result of interaction between the bacteria and the fluids of the body, just as in an *in vitro* experiment with bacteria and serum. The toxic products of interaction in the free and fixed phagocytes are probably of a similar nature—these when sufficient in amount will produce the symptoms of fever, &c., as has been experimentally shown. When lysis occurs the lysed bacterial protein can the more readily gain access to the tissue cells in various parts of the body, and hence the interactions will occur more vigorously. If there is sufficient tissue antibody already present a certain degree of interaction with resulting intoxication will immediately take place, the intensity depending on the relative proportions of antigen and antibody, and in some cases acute death may occur. If death does not occur, there will be a certain degree of desensitisation of the antibody which may lead to freshly arrived

bacterial protein causing no or only slightly increased toxin formation. The arrival of this protein leads to the mobilisation and new formation of circulating antibodies and their tissue cell progenitors leading to a gradually increasing condition of hypersensitiveness. If there is no more protein, the bacteria having been finally completely destroyed in the phagocytes, plasma, &c., then there will be no more toxin production, the animal may recover or die as the result of the intoxication. If, however, the bacteria are not killed, more and more protein will get to these tissue cells and produce interactions leading to fresh toxin formation with periods of cessation or diminution owing to various degrees of desensitisation. In this way the fight goes on till either the animal dies, frequently with a violent terminal reaction producing a sort of acute anaphylactic type of death or recovers, in that finally all the bacteria and lysed protein are rendered harmless. In some cases the animal may die long after the initial infection, long after the bacteria have been killed, by reason of the increased tissue katabolism set up by the infection continuing. That such a process of toxin formation, increase in the amount of antibody, and periodic, partial, or complete desensitisation may occur is seen from the experiments of Friedberger, where it was possible to produce any type of temperature reaction in a normal or sensitised animal by varying the successive doses and intervals of inoculation of the antigen. It cannot, of course, be absolutely put out of court that bacterial protein in itself may be slightly toxic, and that when it gets into the tissue cells produce changes and interaction of the type of those produced by proteoses.

Certain Conclusions.

I think it can be regarded as probable that the toxin is apparently not due to (a) proteolytic degradation of the bacteria by the antibodies; (b) auto-digestion of the plasma; (c) preformed specific endotoxin; but (d) is due to some interaction, the nature of which is as yet obscure, occurring between the tissue and to a lesser extent the free antibodies and the infecting bacterial protein, and according to the intensity of interaction more or less intoxication occurs. The type of intoxication which suggests itself as occurring during the interaction is to my mind closely paralleled by the auto-poisoning produced from damaged muscles during wound shock.

The Croonian Lectures

ON THE

PSYCHOLOGY OF THE SPECIAL SENSES AND THEIR FUNCTIONAL DISORDERS.

Delivered before the Royal College of Physicians of London, June, 1920,

By ARTHUR F. HURST, M.A., M.D. OXON., F.R.C.P.,
PHYSICIAN AND NEUROLOGIST TO GUY'S HOSPITAL.

LECTURE III.*—HEARING, LISTENING, AND HYSTERICAL DEAFNESS.

MR. PRESIDENT AND GENTLEMEN,—Hysterical deafness is probably less rare in civil life than has generally been supposed. In this lecture its ætiology will be primarily discussed in the light of experience gained from the observation of numerous cases occurring in soldiers, among whom it was comparatively common, and a small number of severe cases in civilians.

The noise and concussion produced by the explosion of a shell of high power in the near neighbourhood frequently caused deafness. The patient was dazed or unconscious as a result of the explosion, and when his mind became clear again he discovered that he could not hear. Both ears were generally affected, but the one on the side more exposed to the explosion of the shell was often deafer than the other. The initial deafness was doubtless due to concussion of the internal ear, as it was sometimes associated with vertigo and

temporary nystagmus. One or both drums were often perforated owing to the sudden enormous change in atmospheric pressure. Such a perforation did not greatly affect the prognosis, as the tear generally healed, and in the absence of hysteria normal hearing was restored.

The deafness might pass off in the course of a few hours, but more frequently it lasted for a few days. If it persisted for a still longer period it was almost always hysterical, at any rate in part. The initial concussion-deafness made such an impression on the mind of the soldier that on coming to himself his first thought was for his hearing, and he might be so convinced that he was permanently deafened that he became actually deaf as a result of auto-suggestion. This was especially likely to be the case if for any reason the idea of deafness had previously entered his mind; it was for this reason that a large proportion of cases occurred in men who had old disease of the ear.

The temporary deafness, which was a familiar condition before the war both in gunners and other people who were exposed to the frequent repetition of loud noises, might in the same way become perpetuated and exaggerated by auto-suggestion.

Lastly, organic deafness, especially if the onset is acute, as in that due to involvement of the auditory nerve trunk in cerebro-spinal meningitis, may remain complete after the disappearance of the active disease has been followed by sufficient restoration of the structures involved for a certain amount of hearing to have returned. This, again, is due to auto-suggestion, the final deafness being organic with a superadded hysterical element, which is capable of removal, like all hysterical symptoms, by psychotherapy.

If left untreated without any encouragement, and especially if steps are taken to teach the patient lip-reading, he will become more and more convinced that he is permanently deaf, the effect of the original auto-suggestion being increased by the unconscious hetero-suggestion of those in charge of the patient.

PATHOGENESIS.

Hearing does not consist merely of the perception of impulses conveyed to the brain when the ear is stimulated by sound waves. It is an active process, and in order that sounds may be heard the individual must listen. Inattention during a dull sermon results not only in absence of perception of the words said, but of total deafness to the sound of the preacher's voice. It is clear that impulses to the cortical centre of hearing must be actually interrupted by inattention. The most satisfactory theory is that in the act of listening the resistance at the various synapses in the auditory path becomes diminished by some such process as a throwing out of dendrites, which brings those of contiguous neurones into more intimate connexion. In inattention the synapses are unswitched, the resistance being increased by the retraction of the dendrites.

In animals there is an obvious motor element in listening in addition to the sensory element just considered. This is seen in the movements of the external ear, which is most obvious in those which depend upon flight, prompted by the acuity of their hearing, for safety from their enemies. If one pays attention to one's own sensations in the act of listening, it appears as if some active motor process was taking place in the ear. This probably consists in the simultaneous contraction of the stapedius and tensor tympani muscles, which exert tension on the chain of ossicles in opposite directions. Their function appears to be to regulate the balance of the stapes and so modify the intravestibular pressure that the cochlea may act at its maximal efficiency. The small muscles of the external ear are generally regarded as rudimentary and functionless structures in man. Keith has pointed out that muscles which are never used tend in the course of many generations to disappear. But the muscles of the external ear are invariably found in man, and therefore differ from those rudimentary muscles which have either disappeared altogether or are only found in a minority of human beings. They are, moreover, as well developed in man as in apes. It thus appears probable that they are not as inactive as is generally supposed, and that their activity is not confined to the occasional display of their power by the comparatively small number of individuals who can voluntarily move their ears. How strong the muscles may be was well shown in the case of a soldier who constantly saw in his dreams a

* Lectures I. and II. were published in THE LANCET, July 24th, p. 169, and July 31st, p. 235, respectively.

German whom he had bayoneted in the face; at the same time he developed a bilateral spasm of his face, which recurred every few seconds. Every muscle supplied by the facial nerve was involved, including those of the ear, the movements of which were extraordinarily well marked, although the patient had never been able to move his ears voluntarily. When the dreams disappeared as a result of psychotherapy the spasms also ceased.

On closely watching the ears of a man who was listening intently I found that a definite movement always took place. I have since confirmed this in several individuals. In some cases the outer edge of the auricle moved outwards and forwards on listening to a sound in front, and inwards towards the side of the head on listening to a sound behind. The most vigorous movements I have seen occurred in a man who could move his ear voluntarily, and who was also aware that he moved it when he listened intently. It is, of course, obvious that these movements are mere remnants of the big movements in animals, which have the object of concentrating as many sound waves as possible in the external auditory meatus.

The contraction of the stapedius and tensor tympani might be thought to play a more important part, but careful observations made with W. M. Mollison failed to show the slightest alteration in the process of hearing in complete unilateral facial paralysis, including presumably the stapedius muscle.

When a man is temporarily deafened by a loud noise or by some recoverable disease he finds that he is unable to hear however much he tries, and consequently after a time he gives up trying. That is to say, he ceases to listen, and when the cause of the deafness at last disappears he has become so convinced that he cannot hear that he makes no further attempt to listen. Although the sound vibrations reach his ears in the normal way, they do not give rise to the slightest auditory sensation because of this inattention; he is then suffering from hysterical deafness, the inability to hear having been suggested by the original organic, though temporary, deafness. Severe hysterical deafness developed in a soldier while he was the only Englishman in a German prison. He ceased to pay attention to what was said as he could understand nothing, and in time he ceased even to hear the unintelligible conversation of his companions. His hysterical deafness was rapidly cured by psychotherapy when a year later he came under the care of Major J. F. Venables at the Seale Hayne Hospital.

In hysterical deafness the synapses at one or more of the cell-stations in the auditory path to the cerebral cortex must therefore be unswitched, possibly as a result of retraction of the dendrites. Further evidence for this follows from a study of the auditory motor reflex.

Auditory Motor or Jump Reflex.

A sudden noise normally causes an individual to jump and often to blink, and the pupils dilate; the "jump," at any rate, is a protective reflex and represents the preparation for flight or fight. The blinking cannot be suppressed by the majority of people, although expert revolver shots are said to acquire inhibitory power over it. It is very doubtful, however, whether they ever suppress the pupil reaction.

An officer, whose left motor cortex had been almost completely destroyed, went to the *Man that Stayed at Home* about four months after he was wounded. His right arm jumped violently when the gunshot rang out on the stage, although no trace of voluntary movement returned until three months later. The efferent part of the reflex is thus subcortical. In certain war neuroses of emotional origin, in which the reflex is exaggerated, jumping continues during sleep and deep hypnosis, although the patient does not hear the noise which induces it, even in a dream. The afferent part of the reflex is thus also subcortical, the reflex being quite independent of actual hearing.

Experiments on animals by Sherrington and Forbes¹ confirm the conclusion we reached from clinical observations, that the auditory motor reflex is a function of the mid-brain. They showed that both the posterior corpus quadrigeminum and the medial corpus geniculatum are concerned. The close relation of these centres to the blinking and the sympathetic pupilo-dilator centres in the neighbourhood of the third nerve nucleus, and to the anterior corpus quadrigeminum and red nucleus, in each of which a descending motor tract originates, gives an anatomical basis for this view. In the experiments of Sherrington and Forbes on cats, sounds, especially barks, yowls, and whistles of birds, excited orientative reflex movements of the pinna and neck after the complete removal of the cerebral hemispheres, striata, and thalamus. Reflex movements expressive of anger and aggression—lashing of the tail with bristling of its hairs, and flexion and extension movements of the limbs—were also produced. In our cases of complete bilateral deafness the auditory motor reflex was completely absent, but returned simultaneously with the restoration of hearing as a result of psychotherapy. A very nervous but totally deaf mute remained completely unmoved, never

jumping or showing a flicker of his eyelids during one of the severest thunderstorms I have known, and yet the next day he was completely cured by suggestion under partial anaesthesia.

A slight reflex was present in most cases of severe but incomplete hysterical deafness, but it became less marked, and sometimes disappeared completely, or was confined to a slight dilatation of the pupil when the test was repeated.

The abolition of the auditory motor reflex in absolute hysterical deafness makes it clear that one or more of the unswitched synapses in hysterical deafness must be at the level of the reflex, or still lower in the auditory nucleus or in one of the intermediate cell stations—the superior olive or the nucleus of the lateral fillet, or perhaps in all.

The persistence of the deafness during hypnosis and natural sleep shows that when the inattention of hysterical deafness has lasted for a considerable period, the unswitching of the synapses is more profound than that which normally occurs during deep sleep, in which the synapses can always be forced by a loud noise.

DIAGNOSIS.

In the observations I carried out at Netley with E. A. Peters we found it necessary to discard almost all the criteria formerly used in the diagnosis of organic deafness from deafness due to hysteria or malingering.

History.

Complete bilateral deafness following the explosion of a powerful shell was generally hysterical, though a lesser degree of asymmetrical organic deafness of a more or less permanent nature might be produced at the same time, owing to perforation of the drum or hæmorrhage into the middle ear, both of which were often followed by otitis media or to dislocation of the ossicles. It is still doubtful whether absolute organic deafness ever results from hæmorrhage into the internal ear following aerial concussion, as no anatomical evidence of such an occurrence has yet been forthcoming. Deafness following an acute illness is, at any rate in part, always organic, but we have found that the deafness may be increased as a result of auto-suggestion, no spontaneous improvement in function occurring when the anatomical condition improves.

Other Evidence of Hysteria.

Our investigations have shown that hysterical symptoms may develop in the most normal individuals if the suggestion which provokes the symptoms is sufficiently powerful. No more powerful suggestion of deafness could be imagined than the organic but temporary deafness caused by the noise of an explosion in the immediate neighbourhood. It is therefore not surprising that hysterical deafness has occurred almost as frequently in soldiers, who have no personal or family history of neuroses, as in those with a neuropathic predisposition. Deafness has consequently been the only hysterical symptom in the majority of cases. When, however, the onset was associated with extremely terrifying circumstances, some of the physical results of fear, such as mutism and tremor, were often perpetuated as hysterical symptoms. Thus hysterical deaf-mutism was quite common. In two cases sand was thrown into the patient's eyes from the sand-bags on which the shell exploded, and the hysterical deafness was accompanied by hysterical blindness which followed the conjunctivitis caused by the irritation of the eyes with the sand.

The only conclusion which can be drawn from these facts is that while the association of deafness with mutism or with tremor is very suggestive of hysteria, hysterical deafness occurs most frequently in otherwise normal individuals with no symptoms or history of neuroses.

The Supposed Association of Hysterical Anaesthesia of the External Ear with Hysterical Deafness.

Ever since Briquet² in 1859 described the association of hysterical deafness with anaesthesia of the external ear, this has been regarded as an almost constant phenomenon.

J. L. M. Symns, R. Gainsborough, and I⁴ noted the sensibility of the external ear in a series of 29 soldiers, all suffering from organic deafness, due to various causes and of varying degrees of severity. The ears were first touched lightly with a finger or some wool, sometimes beginning with the deaf ear, sometimes with the ear which was less deaf or normal; at the same time the patient was asked, "Which side do you feel more distinctly?" A similar comparison was then made between each ear and the cheek on the same side. In 28 out of the 29 cases hearing was distinctly better on one side than the other, and in several the latter was normal; 18 of the 28 had partial anaesthesia, and 4 had hyperaesthesia of the affected ear; the better ear was normal in every case. In the single case in which the deafness was equal in the two ears there was no anaesthesia; but this man did not appreciate that he was deaf at all, a slight degree of deafness having only been discovered when the ears were examined on account of other symptoms. The 6 cases of asymmetrical deafness, in which no anaesthesia or

hyperæsthesia was found at the first examination, were then examined again, but a gross form of suggestion was now employed, the patient being asked the following questions: "You feel my finger less clearly when I touch this ear (the deafer one), than this one, do you not?" and "You feel me touch this ear (the deafer one) less clearly than your cheek, do you not?" Four out of the six patients answered "Yes"; in the remaining two the degree of deafness was very slight. In several of the patients anæsthesia was found to be very well marked, and was associated with complete or partial analgesia. So real was this loss of sensation that one patient was subsequently seen putting a pin through the lobe of his ear for the amusement of the other men in his ward.

In a case of severe bilateral hysterical deafness examined in the same way both ears were found to be completely anæsthetic. In a second case, in which one ear was totally deaf owing to organic disease, and the other had been totally deaf owing to hysteria, but was now only partially deaf as a result of psychotherapy, the organically deaf ear was found to be anæsthetic, and the hysterically deaf ear was normal, corresponding with the fact that the deafness of the former was much more severe than that of the latter.

It is thus clear that the supposed association of hysterical anæsthesia of the external ear with hysterical deafness is a complete fallacy, and that anæsthesia is likely to occur in a deaf ear if looked for, whether the deafness is organic or hysterical, so long as the individual is sufficiently suggestible and not too well educated. Thus in all the above cases the patients were soldiers who had been on active service, and our experience has shown how remarkably suggestible the majority of war-worn soldiers are, even in the absence of any hysterical or other nervous symptoms. The results obtained with ordinary hospital patients was consequently less striking. Among four adult male civilians, three females, and two boys, all of whom were deaf in one ear or deafer in one ear than in the other, only one of the adult males had an anæsthetic external ear. When, however, they were shown two test-tubes, one of which was said to contain hotter water than the other, and were asked to say which side was touched with the hotter tube, eight out of nine said that the deaf (or deafer) ear felt the heat more than the other ear, although in every case the same tube was used for touching both ears.

Ten well-educated individuals who were asked whether they would expect any difference between the sensibility to touch in the two external ears if they were deaf on one side only replied in the negative. On the other hand, seven indifferently educated men all replied in the affirmative. The difference is simply due to the fact that no intelligent man would expect his external ear to be anæsthetic if he were deaf, but a man of less education would act upon the suggestion implied in the question without criticising it. The greater frequency of grotesque hysterical symptoms among hospital than private patients, and among private soldiers than officers, is doubtless due to the greater intelligence and greater development of the critical faculties of the latter.

Bone and Air Conduction.

When deafness is not absolute a tuning-fork can still be heard by bone conduction (positive Rinne's test). This shows that the deafness does not depend on changes in the middle ear, even when these are present. But it does not distinguish between the nerve deafness due to organic disease and that due to hysteria. Moreover, the test can only be applied in the slighter cases, as in many instances deafness is absolute and no hearing is possible, whether the sound is conducted by bone or through the air. The vibration of a tuning-fork held on the mastoid process is, however, often felt, and the aerial vibration caused by very loud noises is occasionally appreciated, even when no sound is heard.

Auditory Motor Reflex.

In absolute deafness, whether due to organic disease or hysteria, the auditory motor reflex is absent. In partial deafness it is present, and from what has already been said on this subject it is clear that the presence of the auditory motor reflex does not necessarily imply that hearing occurs. This is of considerable practical importance, as an examination of the reflex has in the past often been used as a test of severe but not absolute deafness in mute children and in supposed malingerers, although a man who says he can hear hardly anything, but shows a normal reflex, is not necessarily a malingerer, for he may be suffering from genuine hysterical deafness or even organic deafness due to a bilateral lesion of the cortical auditory centres.

Persistence During Sleep; Effect of Hypnosis.

As hysterical symptoms are due to suggestion, it might be expected that they would not persist during sleep, and Babinski regards this as a definite law. My experience agrees with his with regard to all other hysterical symptoms which I have investigated, such as paralysis, contractures, and anæsthesia; I have seen several deaf-mutes and one aphonic who talked naturally in their sleep, and a man with

hysterical amnesia had nightmares referring to his period of amnesia. But hysterical deafness, the behaviour of which during sleep does not appear to have been tested by Babinski, is an exception. Thus, greatly to my surprise, I found it quite impossible to wake two of my patients, who were suffering from total hysterical deafness and were sleeping in a hut by themselves, by shouting or by making other very loud noises within a foot of their heads. I convinced myself that deception was impossible, and the hysterical nature of the deafness in both cases was at a later date conclusively proved by their instantaneous recovery with powerful suggestion. In one patient a slight twitch of the eyelids was sometimes observed with a particularly loud noise, but not in the other. It seems probable that a malingerer could be detected by this test, as he would certainly wake if a loud noise was made when he was asleep, whereas in hysterical and organic deafness waking does not follow.

I had expected that hearing would return in hysterical cases during hypnosis, but I found it quite impossible to make the patients whom I had deeply hypnotised obey any command or show any signs of hearing, and no auditory motor reflex was produced. The unswitched synapses thus appear to remain unswitched during hypnosis as they do during sleep.

Character of the Voice; Lip-reading.

In almost all cases of severe deafness due to organic disease the character of the voice changes. It is difficult to understand why there should be any difference in the effect of total deafness on the voice, whether it is organic or hysterical, as the change is simply a result of the patient's inability to hear his own voice. Although in some of our hysterical cases the typical voice of the organically deaf developed, the majority showed no change in timbre or intonation.

When a deaf man teaches himself lip-reading his deafness must be of a high degree. Several patients with hysterical deafness learnt it with remarkable rapidity, so that it cannot be regarded, as has been suggested, as a sign of organic disease. On the other hand, it is very unlikely that a malingerer would ever learn lip-reading.

Vestibular Symptoms and Reactions.

Disturbances in the vestibule as a result of concussion may cause spontaneous nystagmus, which may be accompanied by giddiness and staggering, but these symptoms rarely last for more than a few hours. We have found that the only test upon which almost complete reliance can be placed in the diagnosis of absolute hysterical deafness from absolute organic deafness is the presence of normal vestibular reactions in the former and their loss in the latter. The vestibular reactions are entirely beyond the control of the will, and it is therefore inconceivable that they should disappear as a result of suggestion. As hysterical symptoms are always caused by suggestion, the vestibular reactions must remain unaffected in hysterical deafness. On the other hand, it is highly improbable that any organic lesion could damage the cochlea or the cochlear nerve or nucleus on both sides sufficiently to cause total bilateral deafness without at the same time damaging the vestibules or vestibular nerves or nuclei, so that total organic deafness is almost certain to be accompanied by deficiency in the vestibular reactions. The only exception of which I have heard is a case reported by Fraser⁵ of a congenitally deaf man, in which microscopical examination of both inner ears showed that the organ of Corti was so malformed that hearing was almost abolished, while the vestibules were normal. The caloric reaction was noted on both sides some days before death, and a normal response was obtained.

The vestibular test has proved of great value in cases of total deafness. But it must be remembered that in partial organic deafness the vestibular reactions may be lost in severer cases and exaggerated in slighter cases; any hysterical element which may be present in such cases can only be recognised by the improvement which follows psychotherapy. The vestibular reactions may be investigated by the rotation, caloric, or electrical tests, in all of which nystagmus and giddiness occur in normal individuals, but not if the vestibular nerves are damaged. We have employed the rotation test, as it requires no special apparatus, the patient turning rapidly round five times in one direction and subsequently in the opposite direction. The character and degree of the nystagmus on looking in the direction opposite to the rotation is estimated, and the subjective and objective evidence of vertigo is investigated. The rapidity of the movements of the eyes and their duration should be the same when the individual is rotated clockwise or counter-clockwise. If any inequality is observed, one vestibule must be involved and the other spared, or one must be involved more than the other. An equally simple and satisfactory test⁶ is for the patient to turn five times round a walking-stick, which he holds in the erect position, with his back bent, so that his forehead rests upon the handle of the stick; he then attempts to walk along a straight line marked on the floor. A normal

individual diverges from the line in the same direction as he has been turning, the angle being equal whether he turns to the right or left, but in severe bilateral vestibular disease he walks straight forward, or if the ears are unequally affected the angle differs according to the direction he turns.

The following remarkable case well illustrates the fallacious character of the criteria which were formerly regarded as sufficient to make an accurate diagnosis possible.

Hysterical total deafness in a man of 18 dating from infancy.—G. C., a deaf-mute, 18 years old, appears to have become deaf after a fall on his head some time between the age of 3 and 9 months. His mother is certain that he could hear as a small baby, although at a later date a number of aurists were consulted, who all stated their belief that this observation must be incorrect and that he must have been deaf from birth. With great difficulty he was taught to speak, but he has the characteristic extremely indistinct speech of a deaf-mute. He does not remember ever having heard anything at all, except on rare occasions during the last few years, when he thinks he has sometimes heard a loud noise, though possibly he really only felt the vibrations of the sound. When I first saw him in May, 1919, he appeared to be totally deaf, but there were no signs of middle-ear disease and the vestibular reactions were perfectly normal. The auditory motor reflex was completely absent. I explained to him by means of lip-reading, at which he is an expert, that he could not hear because he had never tried to listen, and that if he once made an effort to listen he would begin to hear. On this first visit he was taught to listen sufficiently to hear his name called close to his ear; this was the first word he ever remembered having heard. The same day he heard his bicycle bell and a motor horn for the first time. During the course of the next three weeks, in which it was impossible to give him more than an occasional short lesson, he learned to hear a number of words, each of which had to be taught separately, as, although he could hear the sound, it conveyed nothing to him until he realised what the word was by lip-reading. When once learned, he could understand it on a future occasion, but found it extremely difficult to continue to listen for more than a few minutes, so progress was slow. At his best he could hear a familiar word from the other side of the room without the voice being raised, but frequently it was necessary to shout a word into his ear. At the same time, he improved sufficiently to be able to hear all ordinary sounds; he could hear a band and he could hear notes played on the piano, but he had no idea of pitch and could not distinguish one note from another. The auditory motor reflex was now normal. I heard from his father on May 9th, 1920, that he continues to make steady progress. He now almost always looks up at once when anybody speaks, and seems to hear most sounds without any obvious effort.

In this case a young man of 18 had been a deaf-mute from infancy and the many aurists who had seen him in the past regarded his condition as obviously incurable; the complete absence of anything in himself or his relations which could be regarded as pointing to a tendency to neuroses, the absolute loss of bone and air conduction and of the auditory motor reflex, the persistence of deafness during sleep, the characteristic speech of the deaf-mute who has painfully acquired the power of making himself understood, and his great skill as a lip-reader might have been taken to prove beyond the shadow of a doubt that the deafness was organic. But the vestibular reactions were normal, and acting upon this alone we were able to prove the functional nature of the condition by restoring his powers of hearing by means of psychotherapy. The deafness which developed when he was about 3 months old must have been due to some organic but evanescent lesion. It occurred at a period when he was just learning to listen, and consequently interrupted his development in this direction. When the organic cause disappeared he had become unaccustomed to listen, and he never learnt to do so again. The deafness was thus really a product of suggestion, and as it is being cured by psychotherapy it can legitimately be regarded as hysterical.

A proper understanding of the psychological process involved in listening and of the disturbance in the process which results in hysterical deafness should lead to a great improvement in the treatment of the latter. When hysterical deafness is associated with mutism it requires no special treatment, as hearing almost invariably returns spontaneously when speech is restored. In order to make this still more certain the patient must be convinced that directly he speaks he will hear his own voice and that he will then hear everything clearly. There is rarely any difficulty in curing the mutism by simple explanation and persuasion, though in our earlier cases we occasionally resorted to the suggestion produced by applying faradism to the larynx or making the patient excited with an anæsthetic.

Treatment of Uncomplicated Hysterical Deafness.

Uncomplicated hysterical deafness is much more difficult to treat, and for a time our results were less satisfactory than in any other hysterical condition. For this reason we were induced to employ various forms of suggestion, although we realised that the methods were not really satisfactory. Suggestion under hypnosis was never of any use, as the patient remained deaf whilst hypnotised and consequently heard none of the suggestions which were made to him. Electricity as a means of suggestion was sometimes successful but often failed. In a number of cases of

absolute bilateral deafness, which had resisted all other forms of treatment for some months, we performed "fake" operations, making a scratch behind the ear in the incompletely anæsthetised patient. I described two cases of this kind with Captain E. A. Peters in THE LANCET in 1917.²

This method of treatment was also not invariably successful, and at the best it was not one which could be regarded as desirable, as it is much more satisfactory for the patient to understand the exact means by which he has been cured than for him to be fooled into a cure by gross suggestion. With increased understanding of the psychological basis of hysterical deafness we were able during the last year of the war to cure a large majority of cases by the most rational form of psychotherapy—explanation, persuasion, and re-education. The patient is made to understand by written explanations how he has become deaf and how the original cause of his deafness has now disappeared; as the deafness was at first organic he could not hear, however much he listened, and consequently after a time he ceased to listen at all. He is next persuaded to listen intently, and is taught that listening is just as active a process as moving and requires a conscious effort on his part until it becomes automatic once more.

Even when a man has completely recovered his hearing it may take some time before he becomes accustomed to the new conditions, especially if he has been deaf for a long period. When caught unawares he often fails to hear, though directly he perceives he is being spoken to he listens and can then hear, even with his eyes closed, so that lip-reading cannot help him. In severe cases he may hear the sound of the voice without being able to distinguish what is said. Re-education is finally required in order that the sounds the patient hears, but at first cannot interpret, can be understood, that words which must at first be repeated separately from each other can be used in continuous sentences, and that the voice which must at first be raised can become progressively more quiet. A similar method of re-education can be employed for the many people who are suffering from some incurable form of deafness, who can in this way be taught to make the most of what powers of hearing they still possess.

Hysterical deafness after being struck by lightning; great improvement with psychotherapy nine years later.—Mr. S., aged 55, was struck by lightning in November, 1911, when in New South Wales. His horse was killed under him and he was left for dead by his companion who was riding with him. He was subsequently picked up and carried to a hospital, where he remained unconscious until the sixteenth day. A burn was found extending from the back of his head down the left side of his body to the hip. When he recovered consciousness he found that he had completely lost his hearing, and that his legs and arms were numb and partially paralysed. He slowly regained his power of movement, but continued to feel peculiar sensations in his limbs. The deafness was associated with a continuous noise in his head which reminded him of escaping steam. It was so persistent that it often rendered it difficult for him to get to sleep. When he left hospital he was told that his deafness was due to fracture of the base of the skull caused by the violence with which he struck the ground when he fell from his horse, as bleeding had occurred from his right ear.

When I first saw him in March, 1920, I found that his vestibular reactions were perfectly normal. He could not hear a whisper at all; loud-spoken words were only heard within 2½ inches from the left ear and 1 inch from the right. Low notes were heard better than high ones. There was no paralysis, but he complained of inability to walk more than a short distance, and he was still troubled with unpleasant sensations in his limbs. I could find no evidence of organic disease, and regarded the deafness as probably hysterical in origin. This opinion was confirmed by Mr. W. M. Mollison, who could find no evidence of disease in either ear. I explained to him that the terrific noise of the thunderclap had produced temporary organic deafness, and that this was the last impression he had before he lost consciousness. It was quite impossible that the deafness was due to a fracture of the base of the skull injuring the auditory nerves, as he had been told, as in that case the vestibular nerves would have been involved at the same time.

I explained to him that having once been deafened he had ceased to listen, and that when the temporary changes produced by the noise had disappeared he could hear again, but he had become so impressed by the fact that he was deaf that he had not tried to listen. He at once improved when he realised that in order to hear he had to listen actively. I gave him a few lessons myself, and he then continued to train himself whilst at home in Scotland. On the railway journey he found that he could hear what other people were saying in spite of the noise of the train, although he had never been able to do this before, and when he got home he found he could hear the voices of his relations which he had not heard since the accident. He trained himself to listen to everything that was happening around him, and for the first time since 1911 he could hear the singing of birds, footsteps in his neighbourhood, and clocks striking.

Although in the past it had been impossible for anybody to wake him by noises, he now found that quite slight noises might wake

him in the night, so that whatever the basis of the hysterical deafness might be, it clearly persisted during sleep, but was now no longer present. When I last saw him, on June 16th, he could carry on an ordinary conversation without difficulty. Mr. Mollison found that with the right ear, which had been previously almost totally deaf, he could now hear clearly spoken words at a distance of 18 inches, and with the left ear he could hear quietly spoken words six feet away, and a whisper at one inch. He himself has noticed that when his better ear is stopped he can carry on conversation when words are spoken slowly and clearly. At the same time his general health has greatly improved, and the noises in his head have almost disappeared. Whilst he learnt to give greater attention to sounds, he learnt at the same time to give less attention to sensations coming from his limbs, and consequently the paresthesia of his limbs gradually disappeared.

Hysterical Hyperacusis.

The nervous individual who has a brisk auditory motor reflex which results in "jumping" at the least sound is familiar in civil life. An exaggeration of this condition was a common symptom in soldiers suffering from all forms of war neurosis which were emotional in origin. In its most marked form the patient jumped violently with sudden sounds, which could hardly be heard at all by an ordinary individual, and louder sounds produced violent universal tremors. The condition persisted during sleep, the patient showing the same exaggerated response to sounds, which did not necessarily wake him, although they generally slept more lightly than they had done before the war. The type of sound which produced this reaction was always one which was in some way reminiscent of shell explosions or other sounds of battle. Many patients realised this quite clearly in their waking state. In one severe case of the kind the patient, when deeply hypnotised, told me that he was always listening for shells, and jumped whenever a sound reminded him of them, although he had been unable to explain the symptom when he was awake.

I have already described the experimental and clinical observations which prove that the auditory motor reflex is a mid-brain phenomenon. I believe that its exaggeration in certain neuroses can be readily explained as a result of a mechanism exactly the reverse of that which leads to its abolition in hysterical deafness. Whereas in hysterical deafness the patient does not listen, a soldier who is in a state of constant terror becomes accustomed to listen for shells with abnormal concentration, and this concentration may persist when he is no longer at the front and no shells are bursting. Instead of the resistance at the synapses in the auditory tract being increased, as in hysterical deafness, it is diminished owing to the extreme degree with which the dendrites are extended. This results in an abnormally brisk auditory motor reflex, and probably also in abnormally acute hearing. We only tested the power of hearing accurately in one patient in whom the jump reflex was excessively developed. Captain E. A. Peters and I found that he could hear sounds at a distance four times as great as the average individual, which means that his power of hearing was 16 times greater than the average, as the intensity of sound diminishes inversely as the square of the distance. His acuity of hearing was most remarkable. Sentences whispered in one corner of a large room so quietly that a group of officers in the centre heard no sound at all were correctly repeated by him, although he was sitting in the opposite corner. The hyperacusis and jump reflex were quite uninfluenced by the administration of 100 gr. of bromide a day, and were only slightly reduced by plugging the ears with plastine.

The increased resistance at the synapses in hysterical deafness persists during sleep. In the same way the diminished resistance in hyperacusis persists, as the patients wake with unusual ease in response to sounds, and also show a brisk jump reflex even when they do not wake.

THE NORMAL BASAL METABOLISM IN MAN,

AND ITS RELATION TO THE SIZE OF THE BODY AND AGE, EXPRESSED IN SIMPLE FORMULÆ.

BY GEORGES DREYER, C.B.E., M.A., M.D.,

FELLOW OF LINCOLN COLLEGE; PROFESSOR OF PATHOLOGY, UNIVERSITY OF OXFORD.

THE present analysis is entirely concerned with the study of basal metabolism—i.e., the metabolism of the individual during complete muscular repose, where a period of 12 hours had been allowed to elapse since taking the last meal. The communication is necessarily preliminary in its scope. The data which have been analysed are only those in which the metabolism was determined indirectly, by measuring the consumption of oxygen in a given unit of time. The formulæ which I have established have all been derived, both in the case of males and females, from the admirable and carefully conducted series of experiments on basal metabolism by Benedict and his co-workers, and the results obtained by other observers and quoted by him. These formulæ have then been applied to the observations of other investigators in America and elsewhere. In the present communication the metabolism of newborn infants and quite young children up to an age of about 5 years is not considered, because, while there exists a relatively long series of observations upon newborn babies, there are but few observations covering the years 1-5, a gap in our present knowledge which it is hoped will soon be filled in view of its great importance.

The relation between body surface and heat production was already suggested by the French writers, Rameaux and Sarrus, in the late "thirties" of last century. In the early "fifties" Bergmann took up the same line of argument in Germany. Müntz, in France, carried out the first actual experiments definitely relating body surface and metabolism in 1880. When the "body surface" law of metabolism is associated with Rubner's name this has its justification in the fact that he was the first spokesman for this theory to support its claims with sufficiently accurate and numerous determinations. Almost synchronously Richet advanced similar views. To give a detailed account of all the arguments put forward by later investigators for and against the "body surface" law, is beyond the compass of this short note. It is only necessary here to refer to the papers of Benedict and Du Bois and their co-workers, and to emphasise the importance of the work carried out by these investigators. Briefly, Du Bois obtained greater accuracy in calculation, using the "body surface" law, by making allowance for the standing height of the individual (as shown in his body surface height charts), while Benedict and his co-workers declared against the view that metabolism was a function of the surface, and they worked out relationships based on weight, standing height and age, and showed the superiority of this method of calculation for the prediction of the basal metabolism of any given normal individual. The relationships are easily calculated from the tables published by this author.

Before discussing the results of my analysis of the various data on basal metabolism I will here state the formulæ by which I have established the relationships between basal metabolism, body weight, trunk length, circumference of the chest and age, as follows:—

(1) The basal metabolism is a function of the weight and the age, which can be expressed in the formula W^n $C \times A^{0.7338} = K_1$ where the power n is approximately 0.5 and K_1 is a constant. This formula indicates that basal metabolism is not a simple function of the body surface.

(2) The relation between basal metabolism and trunk length can be expressed in the formula L^n $C \times A^{0.7338} = K_2$ where the power n is approximately 3/2, though more accurately in males 1.567, in females 1.597, and K_2 is a constant.

(3) The relation between basal metabolism and the circumference of the chest can be expressed in the formula

$$\frac{W^n}{C \times A^{0.1333}} = K_s$$
 where the power is approximately 3/2, though more accurately in males 1.37, in females 1.76, and K_s is a constant.

In previous communications formulæ have been given expressing the relationships between body weight, trunk length, and the circumference of the chest respectively, as follows:—

(4)
$$\frac{W^n}{\lambda} = K_1$$
, where the power n is approximately 1/3, though more accurately in males 0.319, in females 0.313, and the constant K is for males 0.38025, for females 0.36093.

(5)
$$\frac{W^n}{Ch} = K_s$$
, where the power n is approximately 1/3, though more accurately in males 0.365, in females 0.284, and the constant K is for males 0.662, for females 0.30213.

In all of the above formulæ W = net body weight in grammes, C = total number of calories produced in 4 hours, A = age in years, λ = trunk length in centimetres, and Ch = the circumference of the chest in centimetres. Instead of making use of the formulæ (2)

of the females (Formula (1))
$$\frac{2\sqrt{W}}{C \times A^{0.1333}} = 0.1127 = K$$

derived from the 103 persons examined. If in the case of the males all 136 observations are made use of, the constant becomes 0.1018. In comparing the constants for males and females it is evident that, as also maintained by Benedict and other observers, the average male has a greater metabolism than the average female of the same size and age—namely, about 10 per cent. more than the female. In applying Benedict's tables to other observers' data on persons of greatly varying age, such as children, grown-up, and old persons, one is struck in some cases by the marked discrepancy between predicted and observed calorie values of basal metabolism, while in other cases prediction and observation are extremely close, and on an average the correspondence between prediction and observation is better than can be obtained by using Du Bois's surface height charts. In view of this it was of interest to see not only how close the prediction became, using the formula here given, but also to make comparison between the actual constants obtained, using the data of other observers. For this purpose the following table has been constructed:—

Investigator.	No. of persons investigated.	Description.	Average K using author's formula. $\frac{2\sqrt{W}}{C \times A^{0.1333}} = K$	Regardless of sign.		± % deviation for each group.	
				Average % deviation using formula. $\frac{2\sqrt{W}}{C \times A^{0.1333}} = 0.1015$	Average % deviation using Benedict's weight, height, age tables.	Author's formula.	Benedict's weight, height, age tables.
Palmer, Means, and Gamble	8	Men.	0.1037	5.70	4.40	− 2.12	− 4.40
Carpenter, Emmes, Hendry, and Roth	31	„	0.1014	5.94	5.30	+ 0.10	+ 0.46
Magnus Levy and Falk	10	„	0.1000	5.06	5.27	+ 1.50	+ 3.71
„	5	Old men.	0.1045	9.90	10.36	− 2.87	+ 7.94
„	15	Boys.	0.1007	3.46	15.60	+ 0.79	+ 15.60
*Gephart and Du Bois	5	Men.	0.0989	6.10	7.37	+ 2.63	+ 6.75
Du Bois and Aub	6	Old men.	0.0993	8.20	19.83	+ 2.22	+ 17.80
„	8	Boy scouts.	0.0928	9.49	19.70	+ 9.37	+ 19.70

* In only five observations were the age and standing height given, and comparison therefore possible by Benedict's tables. The per cent. deviation for all seven observations by author's formula = 4.59 per cent.

and (3), it is simpler to make use of the following formula:—

(6)
$$\frac{W^n}{C \times A^{0.1333}} = K_s$$
, where W = the theoretical weight in grammes calculated by averaging the weights corresponding to the given trunk length and chest measurements, which can be ascertained from the tables¹ already published, in order to save the laborious calculation of these weights.

The importance of formulæ (2), (3), and (6) becomes evident when one is dealing with persons whose weight has become abnormal as a result of disease, for it is obvious that with loss of weight a metabolism which would be definitely abnormal when calculated in relation to the observed weight might be perfectly normal when calculated in relation to the calculated weight, or vice versa. No such interference with the size of the constant K will occur if the metabolism is calculated in relation to the trunk length (2), and only to a small extent if calculated in relation to the circumference of the chest, (3), or what amounts to the same thing, if the metabolism is calculated in relation to the weight determined from these two measurements (6). Making use of the detailed data for weight, age, and total calories for 24 hours given in Tables C and D in Harris and Benedict's book for men and women respectively, the following constants have been determined. In the

case of the males (Formula (1))
$$\frac{2\sqrt{W}}{C \times A^{0.1333}} = 0.1015 = K.$$

In this case the observations on 16 athletes and 11 vegetarians have been omitted, leaving 109 observations for the determination of the constant. In the case

From the above table it is readily seen how much better the agreement between prediction of metabolism and actual observation is when the author's formula is used than when Benedict's method of calculation is applied to this series of observations by different observers. It is also interesting to note that if the basal metabolism constant had been calculated from the eight series of observations, totalling 88 persons, the average constant would be 0.1004, giving a metabolism only about + 1.1 per cent. greater than the figure obtained from Benedict's and co-workers' observations. If the eight boy scouts of Du Bois and Aub are excluded, for similar reasons as the athletes (greater metabolism) were excluded from Benedict's series of men, the constant is 0.1012, a difference of only + 0.3 per cent., while these series show very marked deviations from his own observations when calculated by Benedict's method. The deviation between observation and calculation for Benedict's own series is, in the case of the males, 5.27 per cent. by the author's formula, 5.33 per cent. by Benedict's method, and 5.65 per cent. by Du Bois's method of calculation. In the case of the women the average per cent. deviations are by the author's formula 6.33 per cent., by Benedict's method 6.36 per cent., and by Du Bois's method 7.53 per cent. respectively. It should be pointed out that the deviations in the case of the author's formula will be considerably reduced if trunk length and chest circumference were considered. The actual data on this point will be published later. From the data available it is to be noted, as already emphasised by Benedict, that athletes have a greater metabolism than persons living a more sedentary life.

Conclusions.

(i.) The formula
$$\frac{W^n}{C \times A^{0.1333}} = K$$
, where n is approximately 0.5 and $K = 0.1015$ in males and 0.1127 in

¹ "The Assessment of Physical Fitness by Correlation of Vital Capacity and Certain Measurements of the Body," by Georges Dreyer, in collaboration with G. F. Hanson. Cassell and Co. 1920.

females, expresses the basal metabolism in an extremely satisfactory manner over a wide range of body, size, and age, and indicates that basal metabolism is not a simple function of the body surface.

(ii.) By means of the various formulæ given in this paper it is possible to predict the basal metabolism of a normal person with greater accuracy than by the methods hitherto suggested.

ON THE SIGNIFICANCE OF BLOOD AND SOLUBLE "ALBUMIN" IN THE STOOLS.

BY ROBERT COOPE, M.D., B.Sc.,

LECTURER IN BIOCHEMISTRY, UNIVERSITY OF LIVERPOOL.

WHENEVER a lesion of the alimentary canal is suspected an examination of the fæces for blood and for soluble "albumin," provided the tests are adequately controlled, is frequently of immense value in diagnosis and prognosis, and may give useful indications of the progress or otherwise of treatment. This paper gives a few practical points concerning the technique and the value of the tests to the ordinary clinician, who too often wholly associates fæcal examinations with complex chemical analyses only possible in a laboratory.

A. Methods. 1. Blood.

A reaction for hæmoglobin (or its derivatives) in the fæces is only of value if the diet is strictly controlled. Any possible source of hæmoglobin (e.g., meat) must be excluded; and drugs, especially those containing iron, should be withheld for some days before the test. For this purpose a milk régime is satisfactory and convenient, as the typical canary-yellow colour of the stools corresponding to the diet makes it easy to recognise whether the portion of the stool examined corresponds or not to the régime.

The question of reagents is of importance. The usual tests employed in clinical work are Meyer's (phenolphthalein reagent), Weber's (guaiacum and ozonic ether or hydrogen peroxide), and the benzidine test (either with fecal emulsion or with a smear on a microscopic slide). A critical examination of these various tests has recently been made by Lyle and Curtmann.¹ They find that the benzidine reaction is unreliable, difficult to control, and too sensitive; that Meyer's phenolphthalein reagent is too sensitive also; and they use a new preparation derived from guaiacum as their reagent for the test.

This criticism is certainly corroborated by clinical experience. Meyer's reagent is altogether too sensitive for the positive diagnosis of an occult hæmorrhage. Its sensitiveness, however, makes a negative reaction of great importance, and enables one to rule out definitely the presence of blood. In practice it is therefore wise first to do the Meyer test,² and, if this is positive, to control by Weber's guaiacum test. A diagnosis of occult blood should only be made when the guaiacum test is also positive.

Description of Tests.

Meyer's test.—A small piece of fæces is taken from the middle of the stool of the milk régime and made into a thick suspension by the addition, if necessary, of a little distilled water. Fill a test-tube about a third full with this fæcal suspension, add a third of its volume of glacial acetic acid, mix thoroughly for a few seconds, and boil. Then cool

thoroughly under the tap. Add about 5 c.cm. of ether, and mix very thoroughly by inverting the test-tube several times. Set aside to separate. If an emulsion forms the addition of a few drops of alcohol will usually bring about a speedy separation, and the supernatant ether layer can then be pipetted off with a test pipette into another test-tube. To the ether extract add about 1 c.cm. of Meyer's reagent by means of a clean pipette; then add a few drops of hydrogen peroxide. If blood is present there appears immediately a deep red coloration, spreading down the tube. Only an immediate and quite definite reaction is to be regarded as positive.

Weber's guaiacum test.—An ether extract is made as above. To this add about eight or ten drops of fresh tincture of guaiacum³ and a similar quantity of hydrogen peroxide. A definitely blue coloration, appearing within two minutes, indicates the presence of blood. A greenish or bluish-green tint is to be regarded as nothing more than "suspicious."

It is wise to do the test daily over a period of several days, as the presence of blood in the stools may be intermittent.

2. Soluble "Albumin."⁴

German authors have shown that the presence of soluble "albumin" in the stools is always pathological in the case of adults. Normally, coagulated protein (in the protein residues of the food) may occur in the fæces; soluble "albumins" taken in the food, however, are always digested in the course of a normal "digestive journey." Even the "albumins" of intestinal exudates are digested and absorbed with comparative rapidity, and therefore if any are found in the stools the exudation must be either great in amount or not too remote from the anus. Thus, the reaction for soluble "albumin" is applicable to the fæces of an ordinary diet, though it is wiser to carry it out on the fæces of a milk régime.

The usual technique is as follows:—

Take a piece the size of a large walnut from the middle of the stool to be examined, triturate well with distilled water in a conical specimen glass⁵ to make a fairly thin emulsion. If the stool is fluid a certain amount can be put straight into the conical glass. Set aside for at least an hour, and then pour off about 20 c.cm. of the supernatant fluid into a suitable vessel, centrifuge the fluid if possible, and then filter; otherwise filter through filter paper previously wetted and plugged at the point of the cone with a little Kieselguhr. Two or three filtrations will probably be necessary before a clear filtrate results, and the filtration is usually slow if the fluid has not been previously centrifuged.

Take 10 c.cm. of this clear filtrate, add 1 or 2 drops of 1 per cent. acetic acid, and if there is any turbidity cautiously add acid drop by drop until the maximum turbidity develops. Then filter until a clear filtrate results. Take some of the filtrate and boil. A heat coagulum indicates the presence of soluble "albumin."

This test is somewhat tedious, and the optimum acidity for both "neutralisation precipitate" and for heat coagulation is often troublesome to obtain. A modification which simplifies the test, and which I have tried with some convenience in a few cases, is the following:—

Take about 10 c.cm. of a fairly clear filtrate from the original fæcal emulsion and add an equal volume of a saturated solution of ammonium sulphate. Filter. The fluid filters more quickly than by the previous method. It may still be necessary to use a little Kieselguhr. Boil the filtrate, carefully adding 1 per cent. acetic acid drop by drop. A coagulum indicates the presence of soluble "albumin."⁶

B. Clinical Findings.

Tests for blood and soluble "albumin" have been carried out upon a series of 156 patients suffering from gastro-intestinal troubles. Not many gastric cases are included; a majority of the cases occurred in a hospital in France, of which unfortunately notes are available only in the intestinal cases. In all the cases the "albumin" was tested for by heat coagulation in the presence of acetic acid.

¹ Except in laboratories, it is best to keep some guaiacum resin, and make up fresh tincture each time it is needed. This is done by dissolving a small fragment of the resin in 2 or 3 c.cm. of 90 per cent. alcohol.

² A more accurate term would be "coagulable protein."

³ A "Gourmet" egg-beater is most useful for this trituration. It consists of a porcelain cylinder, into which fits the beater—a perforated disc attached at its centre to the end of a long handle.

⁴ This modification, suggested to me by Professor Ramsden, lessens the sensitivity of the test by precipitating part of the coagulable protein; but in ordinary clinical work the immense saving in time and trouble probably more than compensates for this.

¹ Lyle, Curtmann, and Marshall: Journ. Biol. Chem., 1914, xix., 445. Lyle and Curtmann: Ibid., 1918, xxxiii., 1.

² Meyer's reagent is made up as follows: Phenolphthalein 2 g., anhydrous KOH 20 g., distilled water 100 c.cm. Dissolve and add zinc powder 10 g. Boil. The decoloration should be complete in ten minutes. If not, add cautiously a little zinc powder until decoloration is complete. Filter while hot. Keep in the dark with a little zinc powder in the bottom of the bottle.

Summary of Results.

Blood and "Albumin" both Present.		Colospasm and chronic colitis	
Acute dysentery (bacillary or amebic) and "acute enteritis"	26	Intestinal fermentative dyspepsia	1
Chronic gastro-enteritis in old amebic dysentery cases—		Duodenal ulcer	1
Amebæ or cysts found 11		Pyloric ulcer	1
Not found 2		Blood Absent, "Albumin" Present.*	
Ulcerative recto-sigmoiditis not included in any of above	2	Sprue	1
Chronic diarrhoea (? bacillary dysentery)	2	(? tuberculous) intestinal dyspepsia and chronic colitis	1
Rectal carcinoma	2	Rectal carcinoma	1
"Chronic enteritis"	2	Blood and "Albumin" both Absent.	
Intussusception	2	Hyperchlorhydria	4
Subacute dysenteriform enteritis	1	Pancreatic insufficiency (primary or secondary)	1
Tuberculous sigmoiditis	1	Post-dysenteric intestinal dyspepsia (bacillary or amebic)	11
Tuberculous enteritis	1	"Acute enteritis"	6
Pyloric ulcer	1	Convalescence from acute dysenteriform enteritis	4
Amyloid degeneration of the intestine	1	Colospasm and mucorrhœa	4
Blood Present, "Albumin" Absent.		Intestinal adhesions or kinks	8
Chronic colitis (? neoplasm of splenic flexure)	1	Intestinal dyspepsia	8
Post dysenteric (Shiga) mucous colitis	1	Obstinate constipation	4
Intestinal dyspepsia in old amebic dysentery case (no amebæ nor cysts)	1	Chronic diarrhoea	3
		Chronic appendicitis	2
		Chronic (mucous) colitis	15
		Chronic cholecystitis or gallstones	14
		Mesenteric hydatid cyst	1

* Several of the acute dysenteries of the first section under treatment arrived at a stage where they had lost a positive blood reaction, while retaining a positive reaction for albumin.

C. Discussion.

The significance of the finding of blood in the faeces is generally known, and little need be said here on the subject. The bleeding may have occurred at any part of the alimentary tract, and in this connexion it is important to remember that patients who use hard toothbrushes or who have a habit of sucking their gums often give the reaction for occult blood in their stools.

Another point of importance is that not all "tarry" stools indicate melæna. A stool of mucous colitis, where the mucus is intimately mixed with the faeces and coloured black with bismuth, may give the typical appearance of "melæna." Again, the intense putrefaction which occurs in certain cases of colitis may give an almost black stool, though no blood is present. On the other hand, in the canary-yellow stool of a milk régime quite appreciable amounts of blood may be distributed through it without altering the colour.

It is obvious that blood in any considerable quantity will give the reaction for soluble "albumin," unless the bleeding occurs so high up in the gut that the "albumin" is digested and absorbed before it appears in the motions. Hence the association of both "albumin" and blood in most cases which involved bleeding in the large intestine.

Soluble "albumin."—A positive reaction for soluble "albumin" is comparatively rare in any ordinary series of gastro-intestinal cases. Marcel Labbé⁷ found it present in one-sixth of the cases in a series of 113 gastro-enteropaths. Goiffon⁸ also found it an infrequent symptom. In this series it occurs in about one-third of the cases, the high percentage being due to the inclusion of many cases of acute dysentery from an epidemic occurring at the time. In ordinary hospital practice it is present in 7 to 10 per cent. of stools sent to our laboratory for investigation. Triboulet, Goiffon, and Labbé all found that it only occurs in grave lesions, ulcerative, inflammatory, or neoplastic, of the digestive tube; and an analysis of the cases in this series suggests the same conclusion.

In the patient with amyloid degeneration of the intestines it would appear that the presence of "albumin" was due to failure of digestion and absorption of the soluble "albumins" of the food. It could hardly be due to hurrying on of the ingested food through the gut, as "albumin" is normally absent even after violent purgatives—an interesting point which Labbé develops when he shows that the presence in

the faeces of undigested foodstuffs, especially muscle fibres, without soluble "albumin," may indicate an accelerated "digestive journey"; but if in addition to undigested foodstuffs soluble "albumin" is present there is some grave lesion of the digestive tube, such as occurred, for example, in one of the patients above, who had a mucous colitis associated with a digestive insufficiency secondary to tuberculous enteritis.

In the other cases in which both blood and "albumin" were present there was either bleeding or ulceration, or both, of the intestinal tract. Apart from two cases of intussusception, three of chronic enteritis (one tuberculous), and one case of a large eroding pyloric ulcer, these were patients in whom the large intestine was involved, and in many of them definite recto-sigmoidal ulceration was seen by recto-sigmoidoscopy.

Blood present, "albumin" absent (7 cases).—In such cases either the bleeding is small, if it be in the large intestine and there is no serious ulceration, or it is far enough away from the anus for the blood "albumins" to be digested and absorbed, as, for example, in cases of pyloric and duodenal ulcers.⁹

Blood absent, "albumin" present (3 cases).—In the case of sprue, the food "albumins" are probably neither digested nor absorbed. The second case was a probable tuberculous enteritis, and the third a rectal carcinoma. Here there was no bleeding, but a sero-albuminous exudation from the ulcerated surface. In addition to these, it was possible in some of the cases of acute dysentery, especially the amebic dysenteries, to follow their progress under treatment both by means of the investigation of their stools and by direct examination by the recto-sigmoidoscope.

In the acute stage there was marked inflammation, going on to ulceration and hæmorrhage, with "albumin" and blood present. As improvement occurred, the bleeding ceased, leaving still a serous exudation from the ulcerated intestinal wall. Now "albumin" only was present, blood absent; and at the same time the corresponding changes in the ulcers themselves were followed from day to day by the recto-sigmoidoscope. A similar process of exudation without bleeding may occur in rectal carcinoma.

Both "albumin" and blood absent (92 cases).—In the great majority it would appear that there was a disturbance of function rather than any actual ulcerative lesion. Even in the cases of acute enteritis in this section it was specially noted that the general condition was well maintained, and this in spite of there being 20 stools a day in some of the cases. The toxæmia so typical of acute ulcerative conditions of the bowel was absent. Some of the patients in this section were treated for acute conditions such as bacillary dysentery, recovered, and months later came into hospital, free now from any evidence of ulceration of the gut, but suffering from extremely persistent functional troubles,¹⁰ dependent perhaps upon extensive changes in the mucosa, or maybe in the intestinal nerve plexuses, as Loeper has suggested.¹¹ In such cases blood and "albumin" are consistently absent.

Position of Lesion.

The finding of blood or "albumin" in the stools does not afford definite evidence of the position of the lesion, and a further simple procedure may show whether it is in the large intestine or not.

The bowel is well emptied by means of an enema, and half an hour later the large intestine is given a lavage of about a litre of normal saline, introduced at body-heat. In acute cases, or in certain recto-sigmoidal ulcerations, a lavage of even 500 c.cm. may be more than sufficient to cause intense pain, and one must be guided by the patient's toleration in deciding how much fluid to introduce. The lavage must be given slowly and at a very small positive pressure, and must be retained as long as possible, up to a period of half an hour. On the fairly clear fluid so obtained the tests for blood and "albumin" are carried out. (The cytology of a centrifuged specimen of the fluid is investigated at the same time.)

⁹ In cases where there is slight bleeding in the large intestine it is possible that a positive blood and a negative "albumin" test may be given because the test for blood is the more sensitive.

¹⁰ Joltrain, Baufte, and Coope: THE LANCET, May 31st, 1919, p. 933.

¹¹ Loeper: Journ. Méd. Français, November, 1919.

⁷ Labbé and Canat: Presse Médicale, Sept. 26th, 1918.

⁸ Goiffon: Presse Médicale, May 2nd, 1918.

In this way light may be thrown upon the condition of the large intestine.

Conclusions.

1. Examinations of fæces for blood are fallacious unless previous dieting and drugs have been suitably regulated.

2. The test for soluble "albumin" in the fæces is probably even more important than that for blood (though both taken together are specially valuable); it indicates either failure of digestion and absorption of food "albumin" (a very rare condition), or the existence either of hæmorrhage or ulceration of the gut. It is almost always associated with some serious condition.

3. The presence of both "albumin" and blood in the stools indicates (a) hæmorrhage with or without ulceration not very remote from the anus, or (b) a severe hæmorrhage higher up the gut.

4. The presence of blood alone indicates hæmorrhage. The nearer the bleeding is to the anus, the less significance it has.

5. The presence of "albumin" alone usually indicates serous exudation, without bleeding, probably near the anus, and presumably the further the lesion from the anus, the larger the exudation must have been. More rarely it indicates a failure of digestion and to absorption of food "albumins."

6. Lavage of the large intestine, and investigation of the fluid so obtained, often gives valuable help in localising a gastro-intestinal lesion.

OBSERVATIONS ON

TWO ACTIONS OF ALCOHOL.

BY W. BURRIDGE, M.A., M.B., B.Ch. OXF.

THE older physicians prescribed alcohol without misgivings, and never found cause to doubt they were doing what was best for their patients. But their course of action has not hitherto been justified by experiments conducted in the laboratory, so that the modern physicians of necessity prescribe alcohol with an element of uncertainty. Any observations assisting them should therefore be of practical value.

Limitations of Previous Experimental Methods.

As a preliminary some possible limitations to the usual experimental method may be considered. One aim in experimental work is to obtain fixed conditions which, in the case of the heart, means perfusing that organ with some modification of Ringer's solution. The inquirer who went into any laboratory where such experiments were in progress would find the experimenter using the best possible solution for the work, and using only that solution. If he pursued his inquiries further he would find different experimenters using different "best" solutions, but each always keeping to that one he thinks best. If the action of a drug be the same under all conditions an experiment conducted under fixed conditions will give accurate and correct general results. But if the expression of the action of a drug differs under different experimental conditions, an experiment conducted under fixed conditions will give only particular results. I have found that the expression of the action of alcohol definitely differs under different experimental conditions. This is especially the case when small amounts of the substance are used. Under the usual laboratory conditions alcohol in small amounts acts, if at all, as a depressant. But under different conditions it definitely augments cardiac activity.

We will consider first the action of 40 per cent. alcohol on the frog's heart. This strength is well outside the limits employed by any other experimenter, and more than one physiologist has come to me in the laboratory and expressed doubts as to the capacity of a heart to survive exposure to it. With the alcohol and the heart at hand there was no difficulty in making a convert. When I used it first I had no doubt I was using a cardiac depressant, and also that it ought to damage the

heart. But certain of the facts observed did not fall directly under those headings. The heart stopped in a more or less contracted condition, and after removal of the alcohol the beats were greater in amplitude than they had been before. To bring that increase of contraction within the scope of a theory of damage or depression was difficult, but it was done.¹ Such a theory, however, cannot include the additional facts following. A heart was used for experiments on the variations in the refractory period produced by this strength of alcohol. It was briefly exposed to the drug and then the disturbance so set up examined. When that disturbance had subsided the heart was briefly exposed to the alcohol again, and so a fresh disturbance set up. Thirty such disturbances were set up and the experiments lasted over two working days. On the third day the heart was still capable of activity though evidently failing. On the fourth day activity was still possible, but later ceased. The point for consideration about these experiments is that no simply perfused frog's heart has survived so long. These facts cannot be brought within the scope of a theory that the alcohol was only a depressant or that it did damage, but on the contrary. After that result one naturally turned to a re-examination of the older records showing the augmentation after the alcohol. The re-examination was greatly assisted by the discovery of a method for ascertaining the maximum contractility of the hearts on which the older experiments had been made. It was thereby found that the old experiments had been performed on hearts that were beating nearly at their maximum. They had little scope for expressing augmentation as improved contraction only, but they showed all they could. In this connexion it is as well to point out that experimenters do not in general know the capacity of the hearts on which they work. It is assumed, but not known, that the heart beats well at the start and that a deviation from that in one direction means better, and in another worse. When the maximum contraction is known it is also known whether a good or bad start was made, whether a heart is beating well or bad at a given moment and by how much, and also the activity becomes directly comparable with that of another heart.

A New Method of Approach.

Having thereby found that the hearts on which the original experiments were made had little scope for showing an augmentation of contraction, attempts were made to give that scope. Instead of letting the cardiac machine run approximately "all out," measures were taken to run the machine at about half power. Then an apparently different result was obtained. Instead of observing a slight increase of contraction after the heart had been treated with the alcohol a great increase was observed—as much as 100 per cent. The differences depended on possibilities. For if the machine at the start were running at 90 per cent. of its maximum, an approximately 11 per cent. increase reaches that maximum. But if at the start it were running at 50 per cent. of its maximum, a 100 per cent. increase on this reached the maximum. After treatment with 40 per cent. alcohol the heart beats at its maximum. If it were beating at 90 per cent. to begin with only 11 per cent. could thereby be added; if it were beating at 50 per cent. at the start that amplitude could be doubled, and was. In presence of the alcohol the action observed was primarily that of depression. The heart stopped and became electrically inexcitable. It stopped in a more or less contracted condition, that contracture being the only visible evidence of any augmentation at this stage. After washing away the alcohol its depression went also, and it was after this that augmentation was definitely manifest. The underlying cardiac change developed by the alcohol, and responsible for this augmentation of contraction, persisted after removal of the alcohol from the heart. It was a slowly subsiding change, and in about 20 minutes or so the heart returned to the *status quo ante*. This strength of alcohol, then, exerts two definite actions on the heart.

There is a depressing action coming on and going away concomitantly with the drug; there is an augmenting

action showing a capacity for persistence after removal of its producer. The finding of that augmentation was entirely contrary to my expectations. When alcohol was first pushed in this manner it was done with a view to obtaining an advanced grade of depression. The depression was obtained, of course, but it was also found to be always accompanied by an advanced grade of augmentation. The two changes had different modes of subsidence which made possible their separation and identification. Having thus found that 40 per cent. alcohol *always* produced two cardiac changes, the hearts were thereafter exposed to gradually lessened strengths of the drug. Except as mentioned below, the same two actions were found. There was a depressing action coming and going concomitantly with the alcohol, there was an augmenting action showing that capacity for persistence. But on making comparison between the members of the series of experiments carried out with concentrations of alcohol varying from 0.5 per cent. to 40 per cent. there could be appreciated the existence of a definite time factor in the development of the stimulating action. The rate of development increased as the strength of alcohol was increased. With 40 per cent. alcohol a high grade of augmentation was produced in a few seconds; with 1 per cent. alcohol a lesser grade took many minutes. No such differences were observed in the rate of subsidence of the change, once it had been produced. This stimulating action of alcohol in low concentrations has been observed by W. E. Dixon³ and F. Ransom,⁴ but its significance missed. The former though the alcohol was being metabolised, the latter that the heart was acquiring "tolerance." I do not think Dixon would suggest the phenomena observed after 40 per cent. alcohol were a result of metabolism or Ransom that they were acquired tolerance. But those phenomena are only a higher grade of the phenomena they observed and so described. Neither of these observers noted the capacity for persistence of this change, nor that when it was present the cardiac refractory period was shortened.

Profound Influence of Two Factors.

The action on the heart of low concentrations of alcohol is, however, profoundly influenced by two factors not taken into account by other experimenters. The factors modifying this action are: (1) The calcium content of the perfusing solution; (2) the amplitude at which the heart is beating. When hearts beat nearly at their maximum and were perfused with a solution of relatively high calcium content—the normal laboratory conditions—small doses of alcohol (2 per cent. or less) either exerted no appreciable action or only depressed—e.g., 1 per cent. alcohol had no appreciable action, 2 per cent. slightly depressed. When hearts beat at about half their maximum and were perfused with a solution of relatively low calcium content so little as 0.5 per cent. alcohol markedly influenced cardiac activity. There was a definite though small depressing action, succeeded by an augmentation much greater than that original depression; 1 per cent. alcohol gave as much as 100 per cent. increase. Under differing experimental conditions the action of alcohol thus also differed. Those giving a positive result had obviously the greater value. Under these latter conditions the action of 0.5 per cent. alcohol differs only quantitatively from that of 40 per cent., whereas under the others there is also a qualitative difference. Calcium is chiefly responsible for the differences.² This element exerts two actions on the heart. Before alcohol can depress it has to overcome the one action of calcium; and before it can augment it has to overcome the other. The more the calcium in the perfusing solution the less readily does the heart react to alcohol.² Ringer's solution has a greater calcium tension than has blood, the latter containing substances such as adrenin, which enable the heart to function in presence of much less calcium than would otherwise be necessary. This greater calcium tension of Ringer's solution confers on the perfused heart a lessened capacity for change which, unless taken into consideration, can vitiate the conclusions drawn from our experiments. It can directly alter the expression of the action of a drug.

The normal heart is bathed in a solution of low calcium tension. If, in addition, it beats at less than its maximum we have the combination of circumstances under which small amounts of alcohol exert a stimulating action far greater than their concomitant depression. Those who employed it directly under those conditions are justified. But alcohol is a substance that cannot be pushed because its depressing action increases more rapidly than the augmenting. It is only when the drug is used in small concentration that augmentation outweighs depression. Those who prescribe repeated small doses do right.

Summary.

1. Alcohol exerts two actions on the heart: (a) A depressing action coming on and disappearing concomitantly with the drug; (b) an augmenting action showing a variable rate of development depending on concentration, and especially a capacity for persistence after removal of its producer.
2. With increase of concentration the two actions do not increase at equal rates, depression increasing faster than augmentation.
3. Low concentrations of alcohol under the experimental conditions specified exert a stimulating action far greater than their concomitant depression.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

A CASE ILLUSTRATING

RE-FORMATION OF ELBOW-JOINT

AFTER GUNSHOT FRACTURE AND EXTENSIVE LOSS OF BONE.

BY WINIFRED F. BUCKLEY, O.B.E., M.R.C.S. ENG.,

LATE RESIDENT MEDICAL OFFICER, ENDELL-STREET MILITARY HOSPITAL.

I HAVE recently followed the whole history of a case in which, after gunshot injury of the left elbow-joint with fracture of the humerus and extensive loss of bone, the joint was ultimately re-formed. The notes are briefly as follows.

Private S., aged 38, was wounded on July 23rd, 1916, and admitted to the Endell-street Military Hospital on August 16th. On admission he had very septic gunshot wounds of the left elbow-joint with much swelling and œdema. The X ray plate showed a supracondylar fracture of the humerus with the lower fragment projecting obliquely forwards, its articular surface being dislocated from the head of the olecranon and radius.

On August 29th an operation was performed for the removal of the separated lower end of the humerus which was located in the joint. The inflammation did not subside for three months and there was very little movement of the joint on his discharge in December, 1916.

As he continued to attend at the out-patient pensioners' department, we were able to take a series of X ray plates, here reproduced, of the joint over a period of three years, and these are remarkably interesting in showing a steady growth downwards of the lower end of the humerus towards the ulna and an actual re-formation of the joint, with hardening and rounding off of the lower end of the humerus on the inner side to fit into the cavity of the ulna. The downward growth of bone continued for two years, the new joint forming during the third year.

The photograph shows the patient's present range of movement. The left arm is two inches shorter than the right, the forearm is fixed in a position of semi-pronation, and there is some weakness of the muscles supplied by the musculo-spiral nerve which is improving under treatment. Otherwise good muscular power is present.

Illustrating Dr. Winifred F. Buckley's Case of Re-formation of Elbow-joint.

EPILEPTIFORM FITS AND COMA IN SYPHILIS.

By C. H. SAVORY, B.A. CANTAB., M.R.C.S. ENG.

WITH reference to the recent discussions upon this subject and the article by Surgeon Lieutenant-Commander F. G. Hitch in THE LANCET,¹ the following notes may be of some interest. They all came under my notice between November, 1918, and May, 1919.

CASE 1.—A. B., Private, R.M.L.I., aged 25, contracted syphilis in April, 1918. Wassermann + + + +. Treatment consisted of galy, nine injections, 0.3 g. each, and mercurial inunctions—ung. hydrarg. 5i. daily. He had had no active signs for six months, but on 10/12/18 he had two typical "epileptiform" fits at 6 A.M. and 10.30 A.M., the latter of which I witnessed. Clinically, it was a typical epileptic fit. But there was no history of previous fits or family history of epilepsy, neither was there any premonitory symptoms or aura. Bromides were administered, but in spite of this the patient had two more fits.

17/12/18: Wassermann was + + +, and it was then suspected that the fits might possibly be specific. Bromides were stopped and large and increasing doses of pot. iodide administered, which resulted in a rapid improvement, headaches being the only symptom. In three weeks there were no symptoms, and another course of six galy's was given with no reaction in any case.

28/1/19: Patient was discharged to duty with no symptoms, and apparently fit in every way.

CASE 2.—C. D., aged 27, leading stoker, contracted syphilis in December, 1918.

6/12/18: Wassermann + + +. Treatment consisted of three galy's (0.25 g.) and ung. hydrarg. 5i. daily as inunctions.

17/12/18: Three typical "epileptic" fits in four hours. No previous or family history of epilepsy. No aura to fits. After the fits there was intense headache and the patient was very dazed and drowsy, lethargic, and torpid.

18/12/18: Lumbar puncture performed and 15 c.cm. fluid withdrawn under very increased pressure. Pot. iod. administered in large and increasing doses.

Result.—Complete recovery in three days and interrupted galy course was resumed in seven days. Examination of C.-S.F. showed: Wassermann, negative; cells, none seen; globulin, absent.

CASE 3.—E. F., aged 19, Private, R.M.L.I., contracted syphilis in September, 1918.

Treatment.—Four galy's (0.25 g.), fourth being given on 18/2/19.

19/2/19: Fifteen hours after galy patient had three consecutive fits in 40 minutes, and hyoscine hydrobrom., gr. 1/200, was given hypodermically owing to their severity. No history of family or previous fits. After fits condition very torpid, dull, and dazed, and acute headache. Lumbar puncture performed immediately, and 10 c.cm. fluid withdrawn under increased pressure. Examination of fluid showed: Wassermann, negative; cells, none seen; globulin, not present. Wassermann of blood + + +. In 48 hours complete recovery, and fifth and sixth galy's were given on 25/2/19 and 4/3/19, with no reaction in either case.

CASE 4.—G. H., aged 40, A.B., contracted syphilis in 1909.

Treatment.—Three "606" and two years intermittently with mercury. No treatment since 1911. Admitted with gumma of inner end of left clavicle and a history of fits in last six months, tinnitus, headache, and of being "strange in his manner." Pot. iod. and galy were given and the gumma cleared up.

24/1/19: Lumbar puncture performed and about 25 c.cm. fluid withdrawn under very marked increased pressure. Relief was apparent in 24 hours.

29/1/19: He was discharged to duty with no symptoms, and his manner and behaviour were markedly brighter and more alert. In this case I witnessed no fits, but there was a definite history of them and no epileptic history. C.-S.F. examination was again normal, with Wassermann negative; Wassermann of blood being + + + +. Urine normal.

Conclusions.

These cases give rise to the following possibilities:—

1. Epileptiform fits in syphilis may not be so uncommon as is commonly thought, and may be an early manifestation.

2. Cases of "epilepsy" suddenly occurring in adults, when there is no previous or family history of epilepsy, might with advantage be investigated for syphilis.

I should like to emphasise the rapid relief apparent after early lumbar puncture and allowing cerebro-spinal fluid to come away until it flowed at a normal rate. Pot. iod. also appeared to assist matters very considerably.

OPIUM IN ACUTE DILATATION OF THE HEART.

By JAMES T. R. DAVISON, M.D.

IN the following case of aortic regurgitation compensation had been established for several years, but was temporarily lost owing to an extraordinary physical effort. The patient's condition was made worse by taking a glass of milk when in an acutely exhausted

state. As a consequence the myocardium gave way and extreme dilatation supervened.

Margaret G., 20 years of age, had rheumatic fever five years ago. When at school her companions had noticed that, on running, an episternal pulsation appeared on her neck. She had never suffered from fatigue but occasionally from palpitation.

On Jan. 24th of this year, being at the seaside, she rapidly ascended 140 steps in a lighthouse. She became very tired, and on the way to the hotel drank a glass of milk. On arriving at the hotel she was seized with an attack of palpitation, accompanied by a feeling of extreme prostration. Next day the temperature rose to 102° F.; the pulse became so quick that it could not be counted. The temperature descended somewhat later on, but the prostration and rapidity of the pulse remained as before. Hypodermic injections of camphorated oil, digitalin, and oxygen inhalations were administered. As she continued in the same state for three days she was brought by train to Buenos Aires. I saw her at midday on the 28th, and found her in a state of extreme prostration. She had air hunger; the pulse was regular, over 200 per minute; enormous dullness over the heart; cardiac impulse extended outside the mammillary line; coughed slightly, and had had a little hæmoptysis in the morning. I gave her a hypodermic injection of camphorated oil. At midnight no change; another injection of oil, and 15 drops of digitalin by the mouth. Next morning I found her in the same condition; the day before she had taken a small glass of milk, which had caused a great deal of pain and discomfort; she had not slept for several days. Her state was now very alarming, and as her heart might become exhausted at any moment and cease to contract I determined to administer a hypodermic injection of one-fifth of a grain of omnopon (a remedy which contains all the essentials of opium); at the same time I gave her another injection of camphorated oil and 15 drops of digitalin by the mouth. As food she was only allowed sugared water and weak broth. I saw her again in the afternoon and found that she had slept three hours and the pulse had come down from 224 to 210. I gave more digitalin and another injection of oil. At midnight I found her completely changed. The pulse had dropped from 210 to 110; she had slept several hours and felt quite happy and contented. Another injection of camphorated oil was administered. On my visit the next morning the report was that she had slept all night. On examining her heart I heard a diastolic murmur in all the areas, with maximum intensity over the upper part of the sternum; a systolic murmur all over the sternum. A later examination of the urine revealed the presence of albumin and of hyaline casts.

Remarks.

In this case the strain on the heart involved in the great effort of ascending rapidly a heavy flight of steps had weakened the myocardium. As a consequence the sympathetic had come to the rescue, and by accelerating the cardiac contractions had essayed to neutralise the depressing effects of the weakened muscle. But, as sometimes happens in the working of the mechanisms designed to direct and protect the organ, the parts are not always well adjusted, and the effects, far from saving the organ, may actually lead to its death. Since opium is supposed to hinder somewhat the synapsis between neurons, I administered omnopon in the hope of separating the corresponding neurons, and thus impede too rapid passage of nerve force along the fibrils.

I tried to give the heart absolute rest so that the myocardium might recuperate its vigour, and so I recommended the patient to remain in bed for a long time. As she felt so well she would not take my advice and got up and went about as usual. I essayed at first to reduce the rapidity of the contractions by means of digitalin, but I soon gave up the treatment, having obtained no practical results; besides that I am loth to interfere directly with the myocardium unless there is rupture of compensation. I preferred to strengthen the heart indirectly by administering arsenic and hypophosphites. I must add that after a time the cardiac dullness was much reduced. I saw this patient three months afterwards and she reported that she felt as well as she ever had done before her sudden illness and that her pulse ranged between 80 and 90.

Buenos Aires.

A SITE near Nel's Poort, Cape Province, is being selected for the contemplated Cape Provincial tuberculosis colony. It is stated to possess all the requisite advantages for such a settlement.

NATIONAL HOSPITAL, QUEEN-SQUARE, LONDON.—Thanks to an emergency grant of £4000 from King Edward's Hospital Fund for London and an extension of the principle of payment by patients, the hospital is again able to maintain the greater part of the work of the institution. It was feared at one time that the whole of the hospital would have to be closed; this catastrophe has been averted, but three wards nevertheless remain unoccupied pending the receipt of increased monetary assistance.

Reviews and Notices of Books.

THE INDUSTRIAL CLINIC.

A Handbook Dealing with Health in Work. By Several Writers. Edited by EDGAR L. COLLIS, M.D. Oxon., M.R.C.P., Talbot Professor of Preventive Medicine in the University of Wales. London: John Bale, Sons, and Danielsson, Ltd. 1920. Pp. 240. 10s. 6d.

THE appearance of this book is an indication of a growing interest in preventive medicine, which some years ago touched the individual at few points only, but whose influence now begins with, or even before, birth and is continued to the grave. A realisation of the place which industrial medicine should occupy in industrial administration has been quickened by the experiences of the last few years; but success in its application depends to a great extent upon the benevolence of the worker, and this benevolence will hardly be accorded until the worker is sufficiently educated to appreciate its importance, an event that may be regarded as one of the benefits to be expected from an advance of true education. Educational policy has not always gone along lines calculated to promote such appreciation. Instruction has often taken the place of education, and not infrequently imagination has been killed instead of being stimulated. In the future the one result will be gained or the other, according to the type of teacher chosen. In the past the teacher of youth has often been a man not only himself incapable of teaching but incapable of learning also.

In the present volume we find grouped a series of contributions from men who have devoted years to their subjects or who have been drawn towards them by recent necessities, and have entirely different outlooks. The first chapter is contributed by Dr. W. F. Dearden, certifying surgeon for Manchester and medical officer of health for the Port of Manchester. This forms an excellent introduction to the medical examination of the worker, and pays especial attention to the examination required for the granting of certificates of fitness for factory workers under 16 years of age and the examination of all workers required by special rules or regulations governing dangerous industries. The material is plainly put forward, and is the result of ripe experience. Those who have had opportunities of observation similar to those of Dr. Dearden will agree with many of his strictures—e.g., upon the sanitary accommodation in many factories—and can only regret that the comment that “the surgeon can do nothing practical towards ameliorating unsatisfactory conditions” is still true. The same may be said of the statement that in the case of personal hygiene “the surgeon can do nothing beyond giving good advice.”

The second chapter is written by B. Muscio, M.A., and it is a sign of the times to find a psychologist collaborating in the production of a book on medicine. The subject treated, “Choosing the Worker,” has a greater importance in medicine than is yet realised; the degree to which a worker fits his environment may be determined largely by selection, while environment in its turn has much to do with his efficiency. No doubt the health of the working population will be vastly improved when periodic examination—psychological and medical—makes it impossible for a worker to remain unknowingly in an occupation for which he is unfitted.

Chapter III., on Industrial Efficiency and Fatigue, has been entrusted to Dr. H. M. Vernon, who is now an investigator to the Fatigue Research Board. This is one of the most difficult sections of the book. The subject is little understood, and, whilst a scientific treatment is demanded, no satisfactory definition of the condition itself is as yet universally accepted. A similar uncertainty may be said to exist with regard to the tests to be used. Dr. Vernon says: “The identification and measurement of the condition of industrial fatigue is by no means an easy one, and the most

reliable test at present available is that of output.” Everyone will recognise the difficulty referred to in the first part of this sentence; those best qualified to judge will perhaps hesitate to accept the statement contained in the second. To measure the condition of a couple of workers with regard to industrial fatigue and to compare the two is very difficult; but to compare the condition of the same worker with regard to industrial fatigue at different times is comparatively easy, though the test employed would not as a rule be that of output, for this is much influenced by circumstances beyond control and often becomes entirely unreliable. Dr. Vernon truly says, “It by no means follows that a fall of output necessarily implies the existence of fatigue.” Conversely, it by no means follows that fatigue is absent when output is maintained. It may be true, as Dr. Vernon states, that, where repetition work was the rule, such conditions as character of the article made, quality of material, nature and speed of machinery remained absolutely unchanged for two years or more; but it can hardly have been strictly true that “the only alteration of conditions was in the hours of labour.” There are conditions of importance besides those mentioned, some of which could scarcely have remained unchanged for the time described. The difficulty of making an accurate determination of industrial fatigue with the methods at present available is very great, but this fact ought to make us all the more careful in excluding every possible source of error. The statement that output is the most reliable test of fatigue has been made previously, but instances given in this article lend little support to such a view. Remarks on the avoidance of industrial fatigue, the length of the working day, overtime, and length of spells, may be commended, though one feels that here is an attempt to treat an extensive subject in an altogether inadequate space, and the object of the particular type of book we are dealing with has been missed. It is to be hoped that more ample space will be allocated to these subjects in the future.

With regard to time and motion study it is true that the former originated with Dr. F. Taylor, but motion study in the fullest sense originated with Gilbreth. Gilbreth's name is mentioned in connexion with the comfort of the worker, and his “fatigue study” is referred to in the literature, but no reference is made to him as the great exponent of motion study, in which he has worked so long, and upon which so much of his reputation rests. Dr. Vernon believes that time and motion study as a part of scientific management “enforces over-pressure on the workers.” But, surely, it is clear that the workers can work at high speed, or rather with high production and without extra fatigue, if unnecessary movements (which are often actually more numerous than the necessary movements in any particular operation) are eliminated. It is owing to the seeming impossibility of getting this fundamental fact understood that so little progress has been made.

Chapter IV., on the Hygiene of Working Conditions, is adequately treated by Dr. Greenwood, the sections on ventilation being likely to be especially helpful. It is to be regretted that the Fahrenheit scale and the English weights and measures must still be employed. The section on Lighting also is treated in a simple and adequate manner, taking account of the class of person likely to use the book. Cleanliness is perhaps one of the most important points to stress at the present time. “Factories must be kept in a cleanly state”; but how many occupiers are capable of understanding (a) exactly what this means and (b) the methods to be adopted to secure it? More attention paid to this particular matter would soon show a result in greater fitness and content and better output amongst the workers. It is very true that “disinfectants can never replace vigorous scrubbing, free ventilation, and sunlight.”

In this section, as indeed is the case with others also, the impression is given of undue condensation, and in future editions it would probably be wise to encourage contributors to give rather more detail, even if this should involve omitting certain parts of their subjects.

Chapter V., on the Hygiene of the Individual, is written by Lucy Cripps, M.B. Here signs of undue preparation are obvious, but other criticisms must be offered. If the statement "the frequency of washing and shampooing the hair depends on the rapidity with which dandruff accumulates" were true, fewer dirty heads would be encountered. And are we really wiser for being told that "the hygiene of the auditory canal is special"? There is truth in the sentence, "Insufficient mastication (these hurried times) is often the main cause of indigestion," but is this the best way of stating it? And would it not be better to leave out dietetics altogether than to attempt to treat such a subject in 24 lines? Throughout the section there are signs of haste, and even of carelessness. We are surprised to learn that "scientific management is doing much to unite labour and capital." One reproach often brought against scientific management is that when introduced in the usual manner it leads to endless difficulties between capital and labour.

The remaining chapters on Food Values in Relation to Occupation, by Dr. Leonard Hill; on Food at the Works, by M. J. Hall, O.B.E.; the Ambulance Room, by Miss J. F. O'Brien; and the Industrial Employment of Women, by Dr. H. B. Adamson, appear to be excellently adapted to the needs of the persons into whose hands the book is likely to fall. Sympathy with, and experience of, the real needs of the factory worker are evidently the possession of those dealing with the sections on factory organisation; without these qualities any endeavour to teach others will always be futile.

We may congratulate Dr. Collis on his attempt to fill a difficult position, but at the same time we would warn him that to secure a real success he must be prepared to scrutinise more carefully the contributions to a second edition.

A MANUAL OF OBSTETRICS.

By JOHN COOKE HIRST, M.D., Associate in Obstetrics, School of Medicine, University of Pennsylvania, &c. With 216 illustrations. London and Philadelphia: W. B. Saunders Co. 1919. Pp. 516. 14s.

THIS work is intended as a companion to the author's "Manual of Gynecology," and includes the methods of teaching he has employed for the last 20 years. It is interesting as illustrating the modern methods of dealing, in vogue in the States at the present time, with various of the complications of midwifery, and those methods differ from the ones prevalent with us in many particulars, it would seem.

Little embryology is given, but we notice a very old-fashioned account of the development of the amnion. We cannot agree that the attendant on a primipara should wait to rupture the membranes until they appear at the vulva, and it is, of course, only one membrane in such cases that requires rupture. In unreduced occipito-posterior presentations the author favours rotation with forceps, or even using the forceps as a lever to pry the head round; this is quite contrary to English teaching. In the treatment of an incarcerated retroverted uterus we are told that abdominal section or the induction of abortion is indicated; the author does not seem to know that if left alone the uterus will right itself in the vast majority of the cases. The section on the measurement of the pelvis is good, and the ingenious method of determining the index of the outlet devised by Dr. Daniels is quoted. It is interesting to note the recommendation of plugging for placenta prævia, and the statement that the vaginal pack is useless in controlling accidental hæmorrhage. The results obtained at the Rotunda by this method should be consulted by the author before condemning it so forcibly. The statement that a Champetier de Ribes bag has a limit of dilatation greater than the normal complete dilatation is not correct of the bag of proper size as designed by Champetier de Ribes, but unfortunately many faulty patterns are on the market. We cannot agree with the condemnation of the axis traction forceps and the suggestion that two pairs of forceps should be carried, a straight pair for use at the outlet and a Simpson's pair for general use,

surely an unnecessary addition to the midwifery bag. The description of the Mauriceau method of delivering the child in a breech presentation does not correspond to that generally given in English text-books, and the omission to state that the traction should be made upon the shoulders seems to us greatly to impair its utility.

The book is well written and contains a great deal of interesting information, but, as we have pointed out, much of it is not in accord with the teaching current in this country.

THE TREATMENT OF SYPHILIS.

By Dr. H. S. BAKETEL. London and New York: Macmillan and Co. 1920. Pp. 167. 13s.

IN this work the author pays special attention to the technique of salvarsan injections. The standard he insists on is a very high one, and one which is only too frequently missed. Against this tendency to adopt slipshod and careless methods, especially in the use of the soluble salvarsan preparations, the author utters a very emphatic word of protest. In the earlier chapters the history and chemistry of salvarsan are summarised. Sufficient information is given to permit of the reader forming some idea of the process employed in its manufacture and of the steps which led to the ultimate discovery of arsphenamine. The use of intramuscular and subcutaneous injections of neoarsphenamine is fully dealt with, and the same conclusions apparently arrived at as those held on this side of the Atlantic. Although the excellence of the therapeutic results obtained from such medication is fully recognised, no sure means have yet been devised for the elimination of the attendant pain.

Dr. Baketel is an advocate of the use of very large doses of potassium iodide and of equally heroic injections of bichloride of mercury. In the case of the latter drug he recommends injections of $\frac{1}{4}$ to 1 gr. doses every other day. Although the possibility of nephritis is admitted, the author has never experienced ill-effects amongst his own patients. In the last few chapters the subjects of neuro-syphilis and of congenital syphilis come under discussion. The final chapter deals with the standard of cure. Altogether the subject of the treatment of syphilis is handled in a remarkably complete manner. The book is well arranged, the illustrations do much to assist the reader in understanding the technique advocated, and the work should furnish a guide to those who have a limited knowledge of the technique and of the "why, when, and how" of intravenous medication.

THE SOCIAL DISEASES.

By Dr. J. HÉRICOURT. Translated, and with a final Chapter by BERNARD MIALL. London: George Routledge and Sons, Ltd. New York: E. P. Dutton and Co. 1920. Pp. x. + 246. 7s. 6d.

IN the preface to this book Dr. Héricourt states that just as the animals are prone to various diseases, so human societies may suffer from sickness, and as there is a social physiology there is also a social pathology. This social pathology, according to the author, consists of four diseases—tuberculosis, syphilis, alcoholism, and sterility. His book was evidently written originally for the French public, and its outlook is necessarily French. Starting from the standpoint that "societies, like men, are the architects of their own misfortunes," Dr. Héricourt proceeds to point to the remedies. These are based in several instances on statistical data of a startling character, but we find the pathological dicta by which they are supported hardly such as would satisfy a British pathologist. As it stands, the book is a severe indictment of modern civilisation, and the final chapter by the translator, on Social Maladies in England, is a no less lurid account of our national shortcomings. While sympathising with the obviously good intention of the indictment the thoughtful reader gains an impression that the whole story is out of proportion, and that there in another side—a saner, soberer, healthier side—of human nature, which is not included in this estimate of the world's social diseases.

A MANUAL FOR MIDWIVES.

By C. NEPEAN LONGRIDGE, M.D., F.R.C.S., M.R.C.P., and J. B. BANISTER, M.A., M.D., B.C., M.R.C.P., F.R.C.S. Third edition. With 51 illustrations. London: J. and A. Churchill. 1920. Pp. 346. 7s. 6d.

THE authors have amplified and revised the third edition of this well-known work. The book is a good one of its kind, well balanced, and striking the happy mean so necessary in a work intended for midwives only. Its utility is much increased by the appendices, which include the rules of the Central Midwives Board, and the very useful series of leaflets from the pen of the chairman, Sir Francis Champneys, which deal with ophthalmia neonatorum, gonorrhoea, syphilis, cancer of the uterus, and cancer of the breast. This is a most valuable series, issued at the request of the Board, and for distribution among the laity as well as midwives. There is also an appendix by Mr. Sydney Stephenson, dealing with the care of the eyes during and after birth. We can strongly recommend this book to pupil midwives and their teachers.

BAILLIÈRE'S NURSES' COMPLETE MEDICAL DICTIONARY.

Edited by CONSTANCE M. DOUTHWAITE, Member of the League of Nurses of St. Bartholomew's Hospital, London. Second edition. London: Baillière, Tindall, and Cox. 1920. Pp. 206. 3s.

THIS is a good dictionary for its purpose. The definitions are crisp and served in agreeable literary form. Names are spelled with remarkable accuracy, except for a certain hesitation, all too common elsewhere, over the possessive case of the famous Robert James Graves. The dictionary can be cordially recommended to nurses and others who require a small book of ready reference on medical and allied scientific terms. The price is moderate and the production of the book is all that can be desired.

BERICHTE ÜBER DIE GESAMTE PHYSIOLOGIE.

Herausgegeben von Professor C. OPPENHEIMER und Professor P. RONA. Berlin: Verlag von Julius Springer. 1920.

THIS useful periodical was suspended during the war and is now again appearing fortnightly, as a continuation of the *Zentralblatt für Biochemie und Biophysik* of Hermann's and also of Maly's *Jahresberichte*, while it is associated with the German Physiological Society. Each section runs to 80 pages, the abstracting is done with care and judgment, while the subjects in review cover a wide area, not only as to the progress in animal, physiological, and pathological chemistry, but also as to chemistry in its application to agriculture, and the ever-increasing sphere of what is known in Germany as "Biophysik." There is no publication exactly comparable to it, either in its scope or its usefulness, in English or, so far as we know, in any other language. It gives reports from some journals which are not likely to be available, at least in these days, to many physiologists.

JOURNALS.

Journal of the Royal Naval Medical Service. July, 1920.—The first place in the July issue is given to a delightful account of a fine piece of successful work by Surgeon Commander L. F. Cope, R.N. Commander Cope reached Belgrade in December, 1918, when he found himself, as he says, "at a loose end," and was told by the senior naval officer to look round and find some occupation that would help the Serbs. This he proceeded to do, and his narrative should be read as a war story, for he gives a most effective picture of the disorganisation of a town that has changed hands in war, a disorganisation quite unknown to us at home, as none of our towns have been fought through. He shows well the difficulty of re-establishing the services of civilised life among the inhabitants of such a city, worn out as they are by the fatigue of war. "The condition of Belgrade was deplorable. The hospitals had been very completely pillaged by the enemy; while the empty wards had been deliberately and liberally befouled with faeces." He first tried to remove filth from the streets, but could get no carts; then he tried to build

destructors, but could get no labour. In searching for labour he found a prison with 200 starving, verminous, and miserable Austrian prisoners. While trying to get this place cleaned he met Major Edward Stuart, a sanitary officer of the American Army, also busy at this work. They combined forces and "proceeded to make things move." They hunted for baths, found 12 and took four, found six disinfectors and seized two, and made a great discovery of cresol and sulphur. Then they were started, and in eight days "killed our first louse in spite of every difficulty officialdom could put in our way." The next day cases of typhus were reported, so something more must be done. As Belgrade had been a great Austrian military centre it was obvious that there must somewhere have been a great disinfecting station. But no one had any knowledge of it. So Cope and Stuart had to quarter the town to find it, and they did ultimately "locate it in a waste of snow-covered fields outside the town." They told the War Minister about it and ordered soldiers in for disinfecting. It was here their real troubles began. They stole six soldiers as a permanent working party; they got a Serbian officer as their adjutant. They chose him as he spoke French and German but no English, so they could discuss matters briefly between themselves without hurting his patriotism by their comments, for there seemed to be little business-like efficiency in the Balkans. They got soap from the Serbian Relief Fund, underclothing from the American Red Cross, electric light and water from the mayor, and coal from the Navy, which also lent an engine-room artificer, who made the disinfectors go (they had been made useless by the Austrians before they left). But the work would never have been done without Miss Simmonds, of the Sandes-Haverfield Canteen, "a Canadian, and the most remarkable woman I have ever seen." "Alone, without authority she took a building begged, borrowed, and stole" its equipment, and made it into a rest-house for Serb soldiers, who loved her and did anything for her. Miss Cullis, a lady sanitary inspector, was also "priceless." She knew no foreign language, and was a stranger in a new country, but "she performed miracles." She got a filthy house for 50 people cleaned inside and out, beds and bedding installed and disinfected when required, stopped thieving, and got the plumbers to do their work thoroughly. Two other disinfecting stations were established, one 40, the other 30 miles from Belgrade. There had been 67 cases of typhus in Belgrade to begin with. In the first week of the delousing campaign 20 cases occurred, but thereafter only 17 altogether, which shows how effective was this work. 15,000 men were deloused. Women and children were put under the care of American Red Cross nurses. Surgeon-Commander Cope tells his story well and gives us good photographs. Our only regret is that he gives us no picture of the Serbian soldiers, "the finest set of men I have ever seen."

British Journal of Children's Diseases. Vol. XVII., April-June. Edited by J. D. ROLLESTON, M.D.—In the first part of a paper entitled "Stigmata of Predisposition to Bone and Joint Tubercle," Mr. W. C. Rivers gives a historical retrospect of the literature dealing with the definite personal characteristics found more frequently in the subjects of bone and joint tubercle than in the non-tuberculous.—In his paper on Traumatic Stricture of the Urethra in Children and Young Subjects, with Some Remarks Concerning the Immediate Treatment of Ruptured Urethra, Mr. A. Ralph Thompson describes three typical cases of traumatic stricture in boys, the prognosis of which he regards as very grave. He strongly recommends suprapubic cystostomy as a routine measure, which greatly assists the adequate treatment of ruptured urethra. He points out that treatment by catheterisation may be carried out, but if it fails excision of the stricture will be required. In an operation for excision of a stricture he emphasises the importance of: (1) preservation of an intact urethra; (2) removal of as much fibrous tissue as possible; (3) deep burial in surrounding strictures of the sutured urethra.—Dr. J. Black-Milne describes two cases of anomalies of growth: Unilateral Macrosomia and Congenital Overgrowth of the Right Leg. In the first case, which occurred in a male aged 18, the right side of the body was affected and there were no anomalies of growth in the family or collateral lines. In the second case, which occurred in a patient of the same age and sex, the right lower limb was 1½ in. longer than the left, but did not show such good muscular development. The chief point of interest in the cases was that the father showed a similar anomaly and of about the same degree. According to Dr. Black-Milne no heredity has been traced in any other cases of hemihypertrophy on record.—In a paper on Unilateral Dwarfism concerned with Congenital Multiple Chondromata Dr. Parkes Weber records a case in a boy, aged 13, whose right tibia, ulna, and radius were unusually short and showed the presence of chondromata on X ray examination.—In a Retrospect of Otology, 1919, Mr. Macleod Yearsley summarises the recent otological literature of paediatric interest.—The abstracts from current literature are devoted to child welfare and otology, rhinology, and laryngology.

FRENCH SUPPLEMENT TO THE LANCET

Under the Editorial Direction of

Professor CHARLES ACHARD,
PROFESSOR OF PATHOLOGY AND THERAPEUTICS IN THE
UNIVERSITY OF PARIS.

AND

Dr. CHARLES FLANDIN, D.S.O.,
CHEF DE CLINIQUE A LA FACULTÉ DE PARIS.

SERUM TREATMENT OF HÆMOPHILIA.

By P. EMILE WEIL,

PHYSICIAN TO THE HÔPITAL TENON.

THE physiological basis of hæmophilia is a more or less considerable retardation of the blood coagulability; otherwise the blood is clinically and histologically normal. This retardation diminishes or disappears when the blood is placed in vitro in contact with human or animal blood serum. The subcutaneous or intravenous injection of human or animal serum corrects the fault in coagulation and momentarily heals the hæmophilia, being both preventive and curative. The serum provides the blood with the missing ferment, thrombokinase or thrombozyme. On these experimental results the present writer has established the therapeutics of hæmophilia.

Treatment of Actual Bleeding: (a) External Hæmorrhage.

Once the hæmophilic diathesis is recognised, treatment varies according as the bleeding point can be reached or not.

Every external hæmorrhage will be treated locally. A piece of gauze soaked in blood serum (simple horse serum, antidiphtheria serum, hæmostyl, &c.) is placed in contact with the wound. In some cases it is well to use serum desiccated in vacuo at 0°; immediate and definitive hæmostasis results.

Contact between the serum and the wound is indispensable. If clots are interposed the coagulating action is not produced. Every hæmophilic wound must be cleansed under all circumstances without hesitation. In dental hæmorrhage dressing of the socket must be preceded by cleansing with abundance of normal saline to remove clots; a plug soaked in serum is then applied. If a hæmatoma has formed, as, e.g., the result of a penetrating wound, it is best to open the hæmatoma, remove the clots, and then apply the serum dressing. General treatment is usually not enough, whilst local treatment procures cessation of the hæmorrhage in a few minutes.

Serum treatment transforms the therapeutics of hæmophilia. It is no longer a noli-me-tangere.

(b) Internal Hæmorrhages.

In cases of internal hæmorrhage (deep-seated closed hæmatomata, hæmarthroses, hæmaturias, &c.) serum should be injected. If the serum is human, venous injection may be adopted, with almost immediate arrest of the hæmorrhage. If the serum is of animal origin (simple horse serum, hæmostyl, antitoxic serum) the subcutaneous method must be used. We do not advise injecting deeply into the muscles; the injections are often followed by small effusions of blood, which would be painful under the pressure of aponeuroses.

As a rule, the quantity injected is from 20 to 30 c.cm. A single dose is enough to arrest the hæmorrhage, stronger or repeated doses being rarely necessary. No drawbacks attend the use of the same quantity for children. Ingestion of serum gives no results in internal hæmorrhage, except bleeding of the stomach, where the serum acts locally.

If the hæmorrhage returns, treatment in the same way must be recommenced. A draught of chloride of calcium (1 or 2 g. daily) may be prescribed, not only to increase the coagulating action of the serum but also to avoid serum disease. The addition of vaso-constrictor

medicaments is not necessary for hæmostasis, but rectal injection, drop by drop, of glucose adrenalin serum seems very often to be useful, especially from the cardiovascular point of view when the loss of blood has been great.

Results of Such Treatment.

Properly directed serum treatment has always given us successful results. We do not advise recourse to gelatin, which could not be administered subcutaneously, but only by the rectum; injections of hemialbumose have seemed of small value.

We do not report here the very numerous cases in which serum treatment has brought about the arrest of bleeding following upon a dental extraction, circumcision, or in cases of hæmarthrosis or hæmatoma; we prefer to state the results of various authors who have used our method. Marcel Labbé has done well with serum injections in several cases of hæmophilic hæmorrhages. Wirth (of Vienna) has by this means stopped hæmorrhages not yielding to any medication. Mauthner (of Vienna) has seen a dental hæmorrhage lasting three days stopped by an injection of 40 c.cm. of serum. Broca, Schiffers, Déjardin (of Liège), Lommel (of Ina) have published similar successes. Le Jemtel (of Alençon) arrested a very profuse external hæmorrhage consequent on an unimportant surgical intervention by an injection of antidiphtheria serum. In their theses on the treatment of stubborn hæmorrhages Eliçagaray and after him Giroud (of Lyons) report several cases in which the method was successful.

In a certain number of cases published the serum treatment failed (Dahlgren, Baum of Kiel). We ourselves have recourse to local, concurrently with general, treatment in open hæmorrhages, and in over a hundred cases we have not failed to master the loss of blood.

Incidental Preventive Treatment of Bleeding in Hæmophiliacs.

Preventive treatment may be incidental or continuous. In the former case the treatment is to enable the patient to undergo a surgical operation. It is enough to inject 20 to 30 c.cm. of animal serum subcutaneously, at most one or more days before the operation.

Since the rectification of the blood is very usually partial, we advise against subjecting hæmophilic subjects to any but indispensable operations—extraction of teeth, opening of abscesses, operations for acute appendicitis, &c.—always bearing in mind the possibility of hæmorrhage. However, in practice we have never had accidents with patients in whom injections had been made before operation.

During the operation the wounds should be plugged with animal serum, and after operation a serum dressing should be applied.

Continuous Preventive Treatment.

In the second and more usual case one has to deal with children with a family history of hæmophilia and repeated hæmorrhage. If the parents understand their duty, continued treatment may be suggested. As the rectification brought about by injections only lasts from six weeks to two months, serum injections must be carried out every two months. Adult hæmophilic patients, who are subject to recurrent accidents—hæmaturia, for example—are quite willing to undergo renewed injections in spite of the possible small anaphylactic drawbacks. In themselves very small and variable, these incidents (fever, urticaria, arthralgia) are not of such importance as to give up a treatment which really transforms the complaint.

We have followed thus half a dozen typical cases of hereditary hæmophilia, in which hæmorrhages were occurring every month or two months; after treatment they ceased for several years to show any symptoms of hæmophilia. At the outset their blood required several hours for coagulation, but at the end only 45, 30, or 14 minutes. The complaint had aged in several months as much as it would have done in 20 or 30 years without assistance.

The prognosis is transformed by the continuous serum treatment. Whilst Carrière, summing up a mass of hæmophilic cases, estimates that 89 per cent. of patients do not live beyond 20 years, I have not lost one out of more than 50 patients. Moreover, under prolonged treatment the complaint becomes so attenuated that it seems as if treatment might even be given up after several years; this was well shown in one of our patients who, after six years of continuous treatment, went through five years of war without misadventure.

The important question presents itself whether, in women of a hæmophilic stock, preventive serum treatment during pregnancy would enable them to bear healthy children. We have not yet had any opportunity to make any experiments in this direction.

Technique of Preventive Treatment.

The technique consists in making subcutaneous injections of blood serum in doses of 20 c.cm. every two months. Later on, after considerable improvement, injections are only necessary every three months. It is hardly possible to put off the injections any further.

In this continuous cure we have generally used animal serums without reason to regret it; but, if it could be done easily, human serums would be preferable. Chalié (of Lyons) has successfully used maternal serum, injected in doses of 30 to 40 c.cm. every fortnight.

Very good results have been obtained in hæmophilic accidents by transfusion of blood. This method, though legitimate in serious hæmorrhage, cannot be recommended as habitual treatment, since blood transfusions cannot be renewed every two months for years on end. In any case, we would utter a warning against subcutaneous hæmotherapy. In a serious case we have seen, after a dose of 25 c.cm. of human blood, an enormous hæmatoma form in the back and abdominal wall, the clot acting as a foreign body and causing a copious hæmorrhage.

COAGULATION OF THE BLOOD:

A STUDY OF THE ANTI-COAGULANT ACTION OF SODIUM CITRATE AND OF THE PART PLAYED BY CALCIUM IN THE BLOOD.

BY MARCEL BLOCH,

CHIEF DE LABORATOIRE IN THE FACULTY OF MEDICINE, PARIS.

THE study of the coagulation of the blood, which ought to be of great use in nosography, has been hampered by the insufficiency of the methods to measure its pathological variations. It is a phenomenon which lends itself with the utmost difficulty to exact measurements. In another place¹ I described numerous methods based on the speed of coagulation *in vitro* (methods of Vierordt, De Mutach, Biffi, Schultz, Angelo Petrone, Brodie and Russell, Wright, and Sabrazès). MM. Achard and Binet have just described a neat technique. The methods of Hayem and P. E. Weil are the simplest, and these workers have made a profound study of blood coagulation in numerous pathological states.

Retardation of coagulation *in vitro* can be observed in normal subjects and in affections such as pneumonia, acute articular rheumatism, associated with an excess of fibrin in the blood; but though direct examination may be able to prove states of diminished coagulability, it is only with difficulty that it allows of appreciating states of exaggerated coagulability. Finally, it is very hard to avoid causes of error.

Consequently the speed of coagulation *in vitro* does not always accurately represent the coagulability. To find some method of measuring "the forces producing coagulation" as they exist in the blood in the vessels it is necessary to prevent them from determining coagulation *in vitro*, to immobilise them whilst leaving them intact, and to restore their activity so as to measure them in the laboratory.² The use of citrate of sodium has enabled me to fulfil these conditions.

Action of Chemical Anti-coagulants in Vitro.

Very many substances are capable of hindering blood coagulation *in vitro* (acids, alkalis, salts, extracts of organisms, venoms, alcohol, &c.). But those alone of importance in establishing a method of measuring are such as are strictly measurable, and do not *a priori* seriously affect the important elements of the blood, as do acids, alcohol, &c. The most carefully studied and frequently used anti-coagulating salts are the oxalates of sodium and potassium, fluoride, and citrate of sodium.

The action of the oxalates is well known from the work of Arthus and Pagès.³ A proportion of about 1 per 1000 in the blood causes incoagulability by the precipitation of calcium in the form of an insoluble compound. The introduction of a new soluble calcium compound (even solubilised calcium oxalate) into the oxalate mixture restores the coagulating property. Theoretically, it is of interest to add that Hammarsten and Pekelharing have shown that the process of coagulation in the oxalated blood is arrested at the stage of the formation of the fibrin-ferment or thrombin. The calcium salts would therefore be necessary to the transformation of the prothrombin into thrombin. But as soon as the thrombin is formed the calcium salts are no longer necessary, and coagulation proceeds even in their absence.

Sodium fluoride added to the blood also produces incoagulability by precipitation of calcium, but the addition of soluble calcium salts does not make the mixture coagulable. Bordet and Gengou⁴ have shown that the precipitate of calcium fluoride thus formed had absorbed all or part of the coagulating ferments and even of the fibrinogen.

Now, if the amount of oxalate of sodium, used in the experiments described above, is slightly increased, results are obtained analogous to those got when fluoride is used. The insoluble oxalate of calcium has therefore operated like calcium fluoride to absorb some or all the substances (in the classic theory called the ferments) which give the blood its coagulating qualities. Even in smaller quantities the sodium oxalate possesses qualities noxious to the "coagulating forces" of the blood, though to a lesser degree. Citrate of soda is not open to these objections.

The Action of Citrate of Sodium.

Like oxalate and fluoride, citrate of sodium makes the blood incoagulable when added at the rate of about 1 per 1000. The addition of a soluble calcium salt—for instance, calcium chloride—immediately restores the coagulating property. The citrate has produced incoagulability by acting on the calcium in the blood. But the difference in action of the citrate and of the oxalates and fluorides is shown directly by an easily repeated experiment. The addition of chloride of calcium to a solution of the latter causes a dense white precipitate. The addition of chloride of calcium to a solution of citrate of soda occasions no precipitate. Contrary, therefore, to the oxalate and fluoride, if the citrate acts on the calcium it does not do so by way of precipitation.

More than ten years ago this action of citrate of sodium on the calcium perplexed biologists (Sabattani,⁵

² Two other indirect methods with the same aim have been described: (a) Wright, Chantemesse; and Cathala take a series of drops of blood from the thumb and examine the quantity of the admixture of oxalate of potassium necessary to prevent coagulation; (b) Et. Brissaud (Paris, Baillière, 1911) makes use of the properties of salted plasma, studied by Bordet and Gengou.

³ Arch. de Physiologie, 1890-1891.

⁴ Ann. de l'Inst. Pasteur, 1912.

⁵ Journal de Physiol. Interne, xxx., 2.

¹ Marcel Bloch: La Coagulabilité Sanguine, Thèse, Paris, 1914.

1900-1901). In modern chemical terminology the calcium is in a latent state. In 1902 Arthus comes back to the question.⁶ By its immobilising action on the calcium salts of the blood the citrate prevents the transformation of the prothrombin ferment into ferment. Similarly citrated milk does not coagulate under the influence of the lab-ferment. Arthus has endeavoured to determine the nature of the phenomenon by means of ingenious experiments.

Citrate of soda is shown to be antagonistic to precipitating salts, and it may be considered as endowed with direct antiprecipitative properties. Now, the alkali oxalates and fluorides possess, on the contrary, no antiprecipitative action with regard to chloride of sodium. We have here a fundamental difference between the salts and the citrates.

We must add that Arthus's stable emulsions resemble colloidal solutions; that the alkaline earth salts and the calcium salts in particular have a very special precipitative action on them; and that these same calcium salts have a fundamental part to play in the blood and its coagulation.

The Action of the Citrate on the Blood Calcium.

In 1902, at the end of his essay, Arthus declared that it did not seem possible to set up any likely hypothesis about the anti-coagulating effect of the citrate in the blood. Contrary to Arthus, M. Luigi Sabattani⁷ thinks that the anti-coagulant action of the citrate can be explained. This is due to his conception of the state of the calcium in the blood. In order that coagulation may take place, not only must a certain quantity of calcium salts be present, but also the ionised state of the calcium. The citrate which does not precipitate the calcium salts leaves the quantity of dissolved calcium intact, which was in the blood and which was enough for its coagulation, but it modifies its state of ionisation and thus annihilates it functionally.^{8,9}

Part Played by Blood Calcium.

When the blood is citrated the pre-existent calcium dissolved is in no way diminished in weight; the citrated blood contains as many molecules of calcium salts in solution as normal coagulating blood, and yet it does not coagulate. It will at once re-coagulate if another calcium salt is added. It must therefore be admitted that the citrate has occasioned a change of state of the blood calcium which completely arrests its action in coagulation.

This phenomenon is not isolated, and modern chemists can readily furnish examples of what they call "bodies in a hidden state." Examples might be multiplied, but it is enough for us to know that a body—metal or metalloid—can exist in a solution in such a state that it is incapable of manifesting its properties. This is what the addition of the citrate has done in the blood with respect to the calcium. The citrate has hidden the calcium.

If we may borrow terms from modern serology without in any way comparing the phenomena, we might say that the citrate inactivates the calcium in a calcic solution—e.g., blood—and that the addition of a little more calcium suffices to reactivate the solution.

Let us now sum up some of the discoveries of modern physical chemistry. The bodies which may be added to a given colloidal solution behave in two ways. Some, the "electrolytes," tend to precipitate the solution—e.g., certain salts of the alkalis or alkaline earths; they are *precipitants* or *instabilisers*. Others reinforce the capacity of the solution to remain in the colloidal state; they are *stabilisers*.

Let us, then, look upon the blood plasma as a colloidal solution. From the physico-chemical point of view this is the modern conception; it is that used by Nolf in order to establish his theory of coagulation. This blood plasma contains *electrolytic precipitants*; they are the calcium salts. If certain bodies like citrate of

sodium are added to the blood they act as *stabilisers* of the colloidal blood solution and prevent the electrolytic calcium salts from exercising their peculiar precipitating properties, and this without in any way affecting the quantities of dissolved calcic salts. The *ion calcium* may therefore with the greatest ease be *active* and provoke coagulation, or *inactive* and bring about incoagulability.

Suggested Hypothesis.

For this reason we feel at liberty to set up the following hypothesis: The blood when fluid and circulating in the vessels is in analysis chemically identical with the coagulated blood in a glass tube. The formation of fibrin is due to a change of physical state of those constituent elements which circulate as fluids in the vessels. Now, if, as we have seen is the case, a simple change of physical state of the calcium is enough to cause or prevent the coagulation of the colloidal sanguine solution in vitro, why not suppose that in the blood circulating in vivo the calcium exists in the inactive latent state? May not simply the issuing from the vessels, exposure to the air, contact with the walls of the recipient and with Nolf's thromboplastic substances (dust, powders) be enough to transform this hidden inactive state of the calcium into an active electrolytic precipitant state with respect to the colloidal solution?¹⁰

It is possible that the mechanism of the activation of the calcium is not simple. The anti-coagulating (antithrombin) substances of the plasma are perhaps "stabilisers" of the colloidal blood solution, antagonistic to the calcic precipitating electrolytes. These are antiprecipitant bodies, which would change their physical state on egress from the vessels under the influence of exterior contacts, lose their stabilising power, and set free the action of the calcium salts.

In any case we are led to assign to the calcium salts of the plasma the main active part in the phenomenon of the fluidity of the blood and the act of coagulation. This part is summed up diagrammatically in the following table:—

Physico-chemical Conception of Coagulation and of the Old "Diastatic Phenomena." Catalytic Coagulation Phenomenon.

There is in chemistry a whole category of phenomena, produced only in presence of bodies, which do not seem to partake in the reactions because they are not modified, but nevertheless they are necessary to their production. This is what is termed *catalysis*. We believe that coagulation belongs to the category of these catalytic phenomena, calcium being the necessary active body, the "catalyser."¹¹

Nolf's idea, the theory of colloidal precipitations, is not as opposed as one might believe to the classical fermentation, enzyme, or diastase theories. Indeed, the modern theory of the diastases is very different

¹⁰ It is well known that certain writers of to-day assign great importance to the sudden changes caused in the physical equilibrium of the serum with sudden disturbances created in the blood colloids "by commonplace, purely physical, causes, such as gold" (Widal). To phenomena of this order would belong the "blood crises" (with coagulation disturbances), anaphylaxis, injections of heterogenous albumins, paroxysmal hæmoglobinuria, asthma, urticaria, &c. See Widal, Abrami, E. Brissaud, Joltrain, Société Médicale, Feb. 13th, 1914; Semaine Médicale, Dec. 14th, 1913; Presse Médicale, June, 1914.

¹¹ This term has already been applied to coagulation. The fibrin ferment performs the transformation of the fibrinogen into fibrin in the manner of a catalyser without itself taking part in the constitution of the fibrin (classical theory).

from that held a few years ago. There is a tendency to draw nearer to the original opinion of Arthus and Naegeli, who denied that the action of the diastases was due to their chemical constitution, but considered that they acted like special transmissible forces, such as electricity and light.

We are acquainted with a large number of enzymic phenomena where the presence of a trace of an acid, alkali, or salt is of fundamental importance, like the trace of calcium salt in coagulation. The importance of other mineral substances (iron, manganese) is as great in other diastatic phenomena (G. Bertrand, Trillat, Phocas). Finally, the discovery of non-albuminoid diastases and of purely metallic colloidal solutions, having the property of diastases (Bredig, Trillat, Robin, Bardet), has completely modified our conception of these latter. Their catalytic action appears to be due, not to the nature of the metal itself, but to the *colloidal form* in which it is presented. Thus, in all these former fermentation phenomena the part played by the mineral element steps into the foreground. Consequently, the part in coagulation which we propose to assign to the calcium is not exceptional. As regards the intimate nature of the mineral element in the catalytic phenomenon, it is of necessity still entirely hypothetical.

Application to Method of Measuring Coagulability.

In practice the blood is first mixed with a measured solution of citrate of sodium (1 c.cm. of blood in 4 c.cm. of citrate of sodium of 1 to 400). The dilution and calcic inactivation prevent the intervention of foreign contacts, the cause of so many errors in direct coagulation observations.

The next step is to divide equal quantities (2/10 c.cm.) of this citrated blood into a series of tubes containing increasing amounts of chloride of calcium (from 0.00005 g. to 0.0005 g. diluted in 4 c.cm. of isotonic salt solution).

At the end of several hours the series of tubes gives a succession of steps in coagulation, incomplete at first in the tubes containing little calcium, then more and more complete as we get near to the amount required for total coagulation. The tubes which mark commencement and end of coagulation are noted. The relationships between the quantities of citrate of sodium and chloride of calcium in these tubes constitute the "indices of coagulability." These indices are notably fixed for normal bloods (two at the beginning and one at the completion of coagulation); the stronger the coagulability the higher the indices, and inversely.

By this procedure we have been able to reveal various experimental and pathological variations of coagulability which other methods did not permit us to appreciate.¹² It allows of the most exact study of the qualities of the coagulum—normal retractility, hyper- or hypo-tractility, or irretractility.

Experimental Applications; Regulating Mechanism of Coagulability.

"In various organs (spleen, pancreas, lymphatic ganglions, small intestine, testes, brain, lungs) it is possible to reveal an anti-coagulating substance, probably identical with the antithrombin which passes from the liver into the blood under the influence of the peptone; in the organs this substance is masked by one or more substances which energetically activate the coagulation of the blood *in vitro*" (Doyon).

These substances, multiglandular in origin and inverse in action, balance each other and their result is coagulability; it is easy to show the instability of this state of equilibrium. If an animal is bled quickly and freely, the succeeding hours show a sudden fall of the indices followed by a reactional elevation above the normal. A return to the normal takes place only after a certain time. (Fig. 1.) If an animal is bled by degrees a fairly durable state of hypercoagulability can be produced.

The same phenomenon may be shown in man, after sudden or repeated hæmorrhages. We have here, perhaps, the explanation of the hypercoagulability found in certain affections (uterine fibroma) and accidents (thromboses, post-operation embolism).

Sudden loss of equilibrium may be observed on the sudden introduction into the animal of certain poisons, in particular of heterogeneous albumins. The experiment of the Schmitt-Müllheim type gives immediate prolonged

FIG. 1.—Fall followed by rise of coagulability after plentiful bleeding in the dog. Index of coagulability on the left of the chart, time in hours at the foot. (a) = commencing, (b) = complete, coagulation.

incoagulability of the blood of a dog which had just had an intravenous injection of propeptone with reactional hypercoagulability.

Clinical Applications: Sudden Disturbances of Coagulability.

We have here a new chapter of human pathology, which opened with the proof of disturbances of coagulability in the anaphylactic shock. They are comprehensible when we note the instantaneous formidable

FIG. 2.—Incoagulability followed by reactional hypercoagulability after intravenous injection of peptone in the dog (shown by the arrow). The asterisk indicates a period 10 hours after the injection. (a) = commencing, (b) = complete, coagulation.

modifications undergone by the plasma elements in the experiment of peptone blood in the case of animals, and after copious hæmorrhages in men and animals. (Fig. 2.)

In the course of experimental anaphylactic shocks (Richet, Riedl, Kraus) it is possible to observe either the more or less complete incoagulability of the blood of the animal, or its hypercoagulability, which is often accompanied by fibrinolysis or redissolution of the clot. In human beings great anaphylactic shocks may be accompanied by phenomena of the hæmorrhagic class (purpura).¹³ Certain symptom-complexes, such as paroxysmal hæmoglobinuria, urticaria, asthma¹⁴ present coagulation disturbances in the course of the crisis (hypercoagulability, irretractility of the clot, fibrinolysis). In the fight against these hæmoclastic crises, or sudden entire losses of equilibrium of the plasma colloids, M. Widal has successfully used intravenous autoserotherapy.

Conversely it has been suggested to combat certain hæmorrhage conditions by means of the hypercoagulability consequent on anaphylactic shocks produced by reinjection of heterogenous serums (Dufour and Crow¹⁵).

Slow Disturbances of Coagulability.

These may be noted in numerous illnesses. With the index method we have determined the coagulability in a number of diseases.

¹² For details of procedure and results see Marcel Bloch, loc. cit.

With marked hepatic insufficiency affections of the liver produce a clear diminution of coagulability. The predominant part played by the liver amongst the organs regulating coagulability explains most of the hæmorrhagic accidents in liver cases.

Lesions of the kidney may also cause a lowering of the indices of coagulation, which partly explains the "hæmorrhagic diathesis" of certain cases of Bright's disease. In extensive œdema the hydræmia seems to have a direct action in reducing coagulability.

Cardiac affections modify the indices in various ways, probably in accordance with the state of the organ or organs most severely attacked in their functions.

The lungs play a most important part in the secretion of coagulating substances (Doyon, Morel and Kareff, Roger¹⁶). Considered clinically a mechanical congestion of the lungs may produce considerable diminution of coagulability (Marcel Bloch¹⁷). The same observation can be made in ordinary pulmonary tuberculosis during the period of softening.

In simple pneumonia hypercoagulability is constantly present, persisting for several days after defervescence. It must be noted, from the point of view of diagnosis, that in influenza, typhoid, and miliary tubercle the indices are normal or lowered. For prognosis lowering of indices of coagulation is a sign of deterioration. It is found above all in pneumonia of alcoholic patients with fatal termination.

In polyglandular and endocrinous affections coagulability may be disturbed. P. E. Weil¹⁸ has recently insisted on the disturbances in coagulation in the course of menorrhagia of women presenting signs of ovarian, thyroid, pituitary, or suprarenal insufficiency.

In toxic infections coagulability is variable. Whilst always increased in acute articular rheumatism, it is usually lowered in typhoid fever, sometimes very greatly so in hæmorrhagic forms.

In certain toxic infectious cases, acute diphtheria, for instance, the indices are raised in spite of the hæmorrhagic conditions. Indeed, the key to the hæmorrhagic symptom complex is not always given by the study of coagulation; the conception of endothelio-vascular insufficiency or dystrophy must be conjoined with it. It may be proved by the "signe du lacet" (Weill, of Lyons). The hypertension induced by light constriction of a portion of the member provokes the bursting of small vessels in the subjacent zone and the immediate appearance of a fine scattered purpura.

The study of the vascular resistance and of coagulability combined permits of interesting distinctions in the purpura and thrombosis symptom complexes. By the side of purpura with diminished coagulability there are purpuras with normal coagulability but irretractility of the clot (insufficiency of blood-plates) and purpuras with normal coagulability and diminution of vascular resistance (endothelio-vascular insufficiency or dystrophy).

Similarly, it is possible to distinguish venous thromboses with increased coagulability (aseptic thromboses in childbirth, coagulability indices increased at the end of pregnancy), distinct from infectious thrombophlebitis, and, finally, thromboses with endothelio-vascular dystrophy, where the coagulability is normal but in which it is easy to prove a weakening of vascular resistance, sometimes hereditary in the family.

In the case of hæmophilia the problem is still more complex. In true hæmophilia we have considerable lengthening of the coagulation period, abnormal coagulability indices, sometimes precocious start, but enormous decrease of index of complete coagulation. Hæmophilia states must be placed beside them for comparison. These are states of very diminished coagulability and vascular resistance occurring in the severe types of purpura, hæmoglobinuria, pernicious anæmia, scurvy, &c., and in the hæmorrhagic forms of the acute exanthems.

Previous Contributions.

The French Supplement to THE LANCET—under the Editorial Direction of Professor Charles Achard, Professor of Pathology and Therapeutics in the University of Paris; and Dr. Charles Flandin, D.S.O., Médecin-Major de 2me Classe, Chef de Clinique à la Faculté de Paris—has appeared on the dates given in the following list, which sets out the titles and authors of the contributions:—

Sept. 21st, 1918: (1) The Microbic Diversity of the Enteric Fevers, by Professor Achard. (2) Post-Typhoid Atony of the Cæcum, by Maurice Loeper, Professor of the Faculty of Medicine and Physician to the Paris Hospitals.

Oct. 19th, 1918: (1) What the War has Taught Us about Tetanus, by Louis Bazy. (2) Tetanus Consecutive to Superficial Wounds and to Trench Foot: Treatment and Prevention, by Professor Raymond, Médecin Principal de 2me Classe.

Nov. 30th, 1918: (1) General Review of French Cardio-Pathology during the War, by Ch. Laubry, Physician to the Paris Hospitals, Médecin Major de 2me Classe. (2) Methods of Estimating Augmentation in Depth of Volume of Left Ventricle, by Dr. Bordet, Director of the Radiological Laboratory of the Centre of Cardiology of Professor Vaquez, Hôpital St. Antoine.

Jan. 11th, 1919: (1) Gunshot Concussion of the Spinal Cord, by Henri Claude, Professor in the Paris Faculty of Medicine, Physician to the Paris Hospitals; and Jean Lhermitte, formerly Chef de Clinique in the Paris Faculty of Medicine. (2) Contribution to the Study of the Manifestations of Emotional Shock on the Battlefield, by Cl. Vincent, Physician to the Paris Hospitals, formerly Medical Officer to the 46th and 98th R.I. and to the 44th B.O.P.

March 1st, 1919: The Surgical Complications following Exanthematic Typhus, by Dr. Paul Moure and Dr. Etienne Sorrel, Prosectors to the Faculty of Medicine, Paris, Médecins Aide-Majors de 1er Classe, Surgeons to the French Hospital at Jassy.

April 5th, 1919: (1) Nervous Complications of Exanthematic Typhus, by A. Devaux, formerly Interne of the Paris Hospitals, Médecin-Major de 2me Classe. (2) Note on the Epidemic Diseases Observed in Rumania during the Campaign of 1916-17, by Dr. Henri Vuillet, late Interne of the Paris Hospitals.

May 3rd, 1919: (1) Malaria During the War, by G. Paisseau, Médecin-Major de 2me Classe. (2) Distribution of Soldiers, Temporarily Unfit through Malaria, in Agricultural Colonies, by Professor E. Jeannelme. (3) Studies on Renal Function in Chronic Nephritis, thesis by Pasteur Valléry-Radot, reviewed by Professor Charles Achard.

June 21st, 1919: (1) Recent Work on Cerebro-spinal Fever, by C. Dopter, Professor, Val-de-Grâce, Médecin-Chef to an Infantry Division. (2) Meningococcal Rheumatism and Arthritis, by Dr. Paul Sainton, Physician to the Paris Hospitals.

Aug. 23rd, 1919: Radiological Examination of Pseudarthroses before and after Operations of Bony Grafts, by Paul Aubourg, Professor Agrégé, Cuneo's Laboratory for Radiology. (Centre for Surgery of Bones, Hospital 75, Cannes.)

Sept. 27th, 1919: (1) Dysidrosis: its Parasitic Nature, by J. Darier, Physician at the Hospital of St. Louis; Member of the Academy of Medicine. (2) The Contagiousness of Favus in Man, by R. Sabouraud.

Nov. 8th, 1919: (1) Secondary Echinococcus, by F. Dévé, Professor at the School of Medicine, Rouen. (2) A Case of Peritoneal Echinococcus, by Charles Flandin, Chef de Clinique Médicale at the Faculty of Medicine in Paris.

Dec. 20th, 1919: French Work on Ictero-Hæmorrhagic Spirochaetosis, by Marcel Garnier, Physician at the Lariboisière Hospital, Paris.

Jan. 31st, 1920: (1) Some Appliances for the Examination of the Nervous and Muscular Systems, by Dr. Jean Camus, Professeur Agrégé of the Medical Faculty in Paris; Médecin des Hôpitaux. (2) The Laws of Tremor, by Dr. Léon Binet, Interne des Hôpitaux, Paris.

THE LANCET.

LONDON: SATURDAY, AUGUST 7, 1920.

Unprincipled Medication.

THE Proprietary Medicines Bill, introduced by Lord ASTOR in the House of Lords on July 13th, raises in particularly acute form the right of the State, or of one department of the State, to restrict the liberties of a flourishing industry on the plea of benefiting the community at large. No adversary of the measure could state the case in stronger terms than those which can be employed in its advocacy. The Bill, now being discussed, sets out to prohibit the sale of such remedies as are sold under a trade name or manufactured by a secret process, unless and until they have been registered by the Ministry of Health, a formality which assumes a disclosure in confidence of their composition. The Bill prohibits altogether, under penalty of heavy fine or imprisonment or both, the sale of remedies purporting to cure certain diseases or disorders, of which a preliminary list of 12 is given in the Schedule to the Bill. The list contains at present the following items: (1) cancer, (2) consumption, (3) lupus, (4) deafness, (5) fits, (6) epilepsy, (7) amenorrhoea and other diseases peculiar to women, (8) diabetes, (9) paralysis, (10) locomotor ataxy, (11) Bright's disease, (12) rupture; and the Minister is to be empowered to extend, as he may think fit, by regulation laid before Parliament, a list already of a comprehensive nature. Other provisions in the Bill disallow the vendor of any proprietary remedy from entering into personal correspondence with those who buy and use his wares, and also the employment of the "trailer" advertisement—being the enclosure with one remedy of printed matter recommending another—becomes illegal. It is evident that if the Bill becomes law it will drastically restrict the operations of a trade forming a substantial section of the London Chamber of Commerce and known to contain more than 300 manufacturers or vendors.

Public opinion is, however, unanimous in support of any measure designed to prevent the sale of fraudulent medicines and of drugs or appliances intended for immoral purposes. All appear to be fully aware of the undesirability of "cure-all" claims. Yet considerable protest has been raised against the Proprietary Medicines Bill in certain journals, wherein it is variously described as an insincere measure designed for the glorification of the Ministry of Health, as a further invasion of public liberty under the pretext of coddling, and as a serious threat to the comfort and convenience of a large section of the public. It is even suggested that the victims of incurable cancer will be deprived by the Bill of the remedies required to soothe and alleviate their sufferings; that, in fine, it is not the public interest but rather the sectional interest of the medical profession which is at the bottom of the changes proposed. The history of the Bill easily disposes of it as a piece of sectional or self-interested legislation. The proposals are

based upon and do not go beyond the recommendations of the Select Committee appointed in June, 1914, to inquire into the sale and advertisement of patent and proprietary medicines and appliances, and to report what amendment in the law was necessary. Doctors, as is natural, were members of that Committee, and doctors were heard in evidence; but in neither case had they any numerical predominance, and the report of the Committee, whose personnel was of a very varied character, was presented with unanimity. Medical men, indeed, did not themselves come out scatheless from an inquiry revealing almost incredible degrees of cupidity on the one side and gullibility on the other. The Committee spoke with regret of medical men who allowed themselves to be made "the catspaw and fool of the fraternity of the secret remedy," and they had evidence in two cases of medical men acting as directors of companies manufacturing secret remedies.

The plain truth is that the lurid evidence laid before the Select Committee, and quoted by Lord ASTOR in support of the measure, was more than sufficient to move any body of citizens, not blinded by prejudice and self-interest, to immediate and forcible action. The sale of proprietary remedies had been increasing by leaps and bounds for some years before the Committee was appointed. Remedies prohibited in America were being shipped in enormous quantities for use in this country. Touting swindlers made fortunes here, only to meet with fine and imprisonment on attempting to do the same in Paris. Australia had refused to sanction the importation of many of the remedies, and more of the literature, freely circulating in this country. Lastly, the attitude of the newspaper and periodical press in regard to secret remedies was, speaking generally, very lax. In 1914 advertisements of proprietary medicines constituted a considerable source of income for many journals; a number of small provincial papers could hardly have existed at all without them, and the medical press was not too carefully censored. This fact led newspapers, either from discretion or under compulsion—we are now quoting from the report itself—to exclude from their columns criticism or discussion of secret remedies. For all these abuses the Select Committee thought that prompt remedies should be found, and upon their recommendations the new Bill has been framed for the protection of the public—and with that sole object.

The Hospital Survey.

REFERENCE was made in a recent number of THE LANCET¹ to Sir NAPIER BURNETT's lucid and informing survey of the financial position of the voluntary hospitals throughout Great Britain and Ireland for the five years 1914-19. From this survey the statistics of the hospitals of London are excluded, as they come directly under the purview of King Edward's Hospital Fund, while there is no information as to 200 hospitals which left the request for information unanswered, and from 32 others which intimated that they had incurred no deficit, and therefore required no special assistance. We should have liked details as to how these desirable conditions were arrived at, while it is possible that some of the 200 who remained silent were similarly fortunate. It is to

¹ THE LANCET, July 20th, p. 83.

be regretted, considering the value at the moment of telling such of the story as present circumstances warrant, that answers should not have been forthcoming from all the institutions approached.

The conclusion is come to from the survey that the hospitals of the country as a whole are solvent. This is founded upon Sir NAPIER BURNETT'S tables relating to the four countries of the kingdom, which show that in 1914-19, for the 670 hospitals taken into account, the total to be regarded as ordinary income was £15,771,346, amounting, with legacies not earmarked for any special purpose (£2,061,830), to £17,833,176; and that the total ordinary expenditure of the same institutions was £17,462,299, leaving an excess of income, plus legacies, over expenditure of £370,877. This, it must be borne in mind, refers to a special period, 1915-19, the conditions of which may never recur, but which will be followed by a period influenced by those conditions and bearing little or no relation to anything that preceded the war. No general excess of expenditure over income plus legacies took place before 1919, when the total ordinary expenditure rose substantially. Before the war there were no problems of hospital finance that required immediate solution if the work was to be kept going, although the increasing need for hospital development in accommodation and equipment was felt by all connected with such institutions, while the level of subscriptions was not rising with the rise in material ease. Now the problems of finance have become urgently pressing on account of the results produced by the war. It will be observed, with regard to the quoted figures, that the solvency of the hospitals as a whole is only to be accepted as proved if we admit that legacies, not earmarked by the testator for any specific purpose, fairly rank as part of the hospital's ordinary income. It is not unreasonable that they should be so treated whenever necessary. To set them aside as capital, so that the interest borne by them alone is spent on the everyday requirements of the institution, is an ideal procedure which all should aim at. At the present time it is a counsel of perfection, which in many cases could not be followed without reducing the usefulness of the hospital. To borrow involves paying a higher rate of interest than the legacies, if invested, would be expected to bear. The money once spent cannot, however, be used for those renovations, expansions, and developments which are not to be looked upon as objects of ordinary annual expenditure. It is exactly the need for extraordinary expenditure which is pressing with many hospitals. Some have incurred debts through struggling to keep efficient and progressive during and since the war. Others have only remained more or less free from debt through refraining not merely from expansion and development, but from necessary repairs, cleaning, and upkeep. To the conclusion, therefore, that the voluntary hospitals as a whole exhibit sufficient vitality to enable them to "carry on" a provision has to be added: they must be assured a fair start in a new era of peace—an era characterised by enormously higher prices, by nursing staffs at increased salaries working for shorter hours, and by ambitions to benefit the public stimulated rather than diminished by the difficulties to be overcome.

The re-establishing of hospital finances upon a satisfactory basis is being achieved in London by King Edward's Hospital Fund, with the recent

distribution of £250,000 from the capital of its own Fund, and with the still more recent gift of a like sum, entrusted to the Fund by the Joint Finance Committee of the British Red Cross Society and the Order of St. John of Jerusalem. This opportune gift, announced by Lord FINLAY on July 23rd, has already been allotted to hospitals which are prepared to treat ex-Service men, and is to be devoted to improvements rather than maintenance. It does not help these hospitals to catch up with their outstanding arrears of necessary repair and replacement. The immediate need of the hospitals of the United Kingdom outside London remains to be met; it is admittedly not so urgent. There are hospitals which can show a small excess of ordinary income, or of income plus legacies over expenditure, but it is not possible, and would not be just, to take from these in order to pay the debts of those whose expenditure has exceeded what they have received. Also, Sir NAPIER BURNETT points out, it would not be fair to penalise those hospitals which have kept within their income by only subsidising those which have exceeded it. He advises that from any fund, hereafter available for the purpose, grants should be made upon inspection of individual hospitals by a competent authority constituted for that purpose. Further than this, he considers that for London and the country a sum of not less than three-quarters of a million is needed to meet the cost of alterations and repairs to buildings, and other matters with regard to which there are now five years of arrears to be made up. This means the expenditure of a million for immediate purposes, quite apart from an urgent need in many places for increased hospital accommodation. The provision of this further accommodation, as well as the more pressing matter of placing the hospitals as they stand in a satisfactory financial position, constitute a national question, and as to this Sir NAPIER BURNETT writes at the conclusion of his survey, which is addressed to the Joint Council of the British Red Cross and Order of St. John: "On another occasion I hope you will allow me to put before you some suggestions as to how far the State should be called upon to render assistance, and what the basis of such assistance should be." It is satisfactory to observe that, after a close study of existing conditions, the State assistance postulated does not exceed something in the nature of a grant in aid, supplemented by necessary changes of organisation and administration. The necessity will still remain for continued and increased generous contribution by those who have the power to give. After all, the voluntary system can only be saved if the public have the mind to save it.

The Significance of Sudden Cures.

To lose a sense of the marvellous is one of the penalties of advancing years; it is a sad day when the grown-up ceases to wonder at the great things of Nature and Art, and equally tragic when the physician is unimpressed by life and death. It is, indeed, a wonderful thing to feel the pulse beat again in response to some heroic remedy, to see the pallor of apparent dissolution replaced by the faintest flush of returning life. Doubtless such dramatic incidents are less common in everyday professional work than the long struggle against

disease, unrelieved by any particularly rapid alteration in a favourable or adverse direction. To most of us, in fact, a sudden cure, apart from the occasional striking turns in the course of acute organic affections, or the results of operative or manipulative interference, is suggestive of a hysterical or functional state; while what is unexpected, and therefore miraculous to the lay mind, is a therapeutic commonplace to the neurologist.

As all the world knows, rapid cures of hysterical disabilities have occurred with monotonous frequency, and, variable though the methods may be whereby they are effected, few will be found to deny a common factor in the underlying mechanism, with a knowledge of whose action an ever-widening circle of neurologists and psychotherapists are familiarising themselves, to the increasing benefit of the sufferers from psychogenic disease. None of those who thus daily come in contact with the manifestations of hysteria is likely to claim any supernormal powers beyond those of his fellows; on the contrary, intimate acquaintance with the why and the wherefore has reduced the "marvels" of psychotherapy to the level of cause and effect. It is, therefore, with some curiosity that we turn the pages of "Twenty Cures at Lourdes,"¹ a recently published translation, by two members of the Order of St. Benedict, one of whom has a medical degree. We find ourselves in sympathy with the assertion, both of the author in his introduction and of Sir BERTRAM WINDLE in his contributed preface, that the cases therein cited with some detail are to be judged on their medical merits by medical men, who are to be the final arbiters whether, as Sir BERTRAM WINDLE believes, "such cases are wholly outside the experience of ordinary medicine" and whether they "fail to follow recognised laws." We may select the case of GABRIEL GARGAM, since Dr. DE GRANDMAISON says it "is certainly one of the most interesting and extraordinary to be met with in the annals of Lourdes."

GABRIEL GARGAM, a post-office employee, was in a railway collision on Dec. 17th, 1899, was hurled violently many feet away into snow, and was not picked up till some seven hours afterwards. It was then found that he was "covered with wounds," had fractured his collar-bone, and was paralysed in the lower limbs. He came under the care of Dr. DEGRESSAC, of Angoulême, who reported a year later that he had rigid paralysis of the lower extremities, with pronounced wasting of the same, loss of all forms of sensibility up to the level of the pelvis, exaggerated deep reflexes with ankle clonus, exceptionally brisk abdominal reflexes, slight bladder difficulty in certain positions only, and distinct pain on pressure over the second lumbar vertebra. The arms were normal, but the trunk was rigidly paralysed in extension. Six months later the same practitioner noted increasing emaciation, pains more or less all over, and similar objective signs to those just mentioned. On these data Dr. DEGRESSAC made a diagnosis of amyotrophic lateral sclerosis, and pronounced the condition incurable. His partner, Dr. TEISSIER, diagnosed diffuse meningo-myelitis from compression of the cord, and Dr. DE GRANDMAISON, favouring the latter diagnosis, says: "In all probability the second lumbar vertebra is where the initial traumatism occurred."

Now it is superfluous to point out that any acquaintance with the elementary facts of neurology would enable the physician at once to exclude amyotrophic lateral sclerosis, in view of the com-

plete loss of all forms of sensibility in the legs as far as the pelvis; that would be the last disease to be suggested to him from consideration of the facts connected with the onset of the affection in GARGAM's case. The alternative diagnosis of compression meningo-myelitis is excluded with equal facility. A traumatic lesion at the second lumbar vertebra corresponds to the lower part of the conus medullaris and the cauda equina roots, and would produce an atonic paralysis with absence of the deep reflexes and with gross sphincter impairment. It is a simple impossibility for a compression at that point to give rise to a rigid paraplegia of trunk and legs with exaggerated deep reflexes and ankle clonus. Leaving these patently erroneous diagnoses, what are we to think of a rigid paraplegia involving the trunk muscles in which the abdominal reflexes are extremely active? The tyro in neurology knows that observation alone casts the gravest doubts on any diagnosis of organic pyramidal disease at all. In none of the reports is mention made of the plantar reflexes, an omission which, with others that will at once occur to the neurologist, renders the clinical description almost valueless and shows that no reliance can be placed on Sir BERTRAM WINDLE's statement that "all the cases are fully dealt with in a clinical manner."

On such data as are given, however, anyone familiar with nervous disease would make a diagnosis of an ordinary hysterical paraplegia, nor is there a single symptom or sign in the account that is incompatible with that diagnosis. We are not in the least surprised, accordingly, to be told that during the procession of the Blessed Sacrament at Lourdes some twenty months, apparently, after the accident, GARGAM, who was lying on a stretcher, rose to a sitting position and exclaimed, "I am cured!" making a rapid convalescence. We are astonished, however, that the case should be cited seriously in support of the contentions of the Lourdes authorities. Dr. DE GRANDMAISON invites the criticism of the medical profession, and we have taken him at his word. One of the most extraordinary cases turns out to be one of the simplest. So far from its being wholly outside the experience of ordinary medicine the exact reverse is the case, and we should hesitate to waste time over such banalities were it not that the book challenges the accepted interpretation of the influence of psychical over physical states. Sir BERTRAM WINDLE says "in cures like that of GARGAM it is abundantly clear that there was no kind of suggestion," a rash statement to make when no hint is given of any psychological examination of the patient. GARGAM made a good recovery and has continued, apparently, in excellent health. Identical recoveries are being made daily by patients who have the good fortune to come into the hands of those who know their work, thanks to the immense impetus given to the study of the subconscious mind by the experiences of the war. It is because of exactly such cases that the teaching of clinical psychology and psychotherapy should be encouraged in the medical schools; thence will issue a generation of practitioners better equipped than their predecessors to deal with the protean manifestations of the mind diseased. When neurological diagnosis reaches a higher standard, and functional cases are recognised and treated by the expert practitioner long ere the disease becomes firmly established, pilgrimages to grottos will cease.

Annotations.

"Ne quid nimis."

THE WORK OF THE NATIONAL PHYSICAL LABORATORY.

THE recently issued report of the National Physical Laboratory for the year 1919 is replete with medical interest in so far as it relates to departments engaged in the standardisation of instruments essential in practice. Apart from medicine the authorities—and the general board includes the leaders of scientific research in all directions—have been able for the first time to disclose the details of certain war work of a confidential character which curtailed the normal activities of the laboratory in relation to research and the tasks of standardisation. It was not possible, for obvious reasons, to give details bearing on war material in the reports made by the heads of departments, or to refer to the special work in progress. The report now presents some account of the war work undertaken and, while necessarily still incomplete, the particulars furnished indicate the importance of the duties discharged by the laboratory in relation to the war. The cataclysm has proved a catalyst in so many directions, and not least in stimulating the activities of the National Physical Laboratory.

Coming to work of medical significance, reference may be made to the standardisation of clinical thermometers. The laboratory was originally asked to arrange for the testing of 20,000 clinical thermometers per week, but it was soon realised that the number to be dealt with would be about 30,000 per week, and provision had to be made for this amount. This demand on the resources of the laboratory arose out of the Clinical Thermometer Order of the Ministry of Munitions in October, 1918. It would appear from the report that the average number of clinical thermometers rejected at the present time is slightly over 3 per cent., while at the beginning of the Order the number was about 5 per cent. This official movement has undoubtedly had the effect of making the clinical thermometer a very accurate instrument at the service of the clinician. The publication in our columns of a series of articles may be recalled for they drew attention to the importance of official standardisation in this matter.¹ These articles form an impressive memoir of the evolution of the mercury column as an index of temperature from about 1866 to the present time. It is also interesting to note that Sir Clifford Allbutt was the pioneer of the present small type of accurate clinical thermometer.

A number of problems connected with the optical abilities and disabilities of glass was also investigated by the National Physical Laboratory, and the results were most satisfactory, the work in this direction having established the important fact that this material can be made as well at home as abroad. Upon this it should follow that the manufacture of special glass for lenses involved in the construction of, amongst other things, microscopes, spectroscopes, saccharimeters, polarimeters, and photographic accessories will remain a home industry. Not less ahead was the work on radium testing. The number of samples of radium of high content tested during the year was 88, containing altogether about 6175 mg. of radium bromide of the approximate value of £80,000. Details as to the efficiency of the preparations submitted are given in the report. X ray investigation took a minor position in the laboratory's work owing to pressure in other departments in connexion with the war, but preparation is now being made in regard to the measurement of the absorptive qualities of materials

used for protective purposes in radiography. There have been unnecessary martyrs in this field, and among them members of our profession have suffered and died not knowing what potentialities for evil were hidden in these radiations. Lastly, the progress of medical research is clearly dependent upon the accuracy of the laboratory apparatus placed at the disposal of the investigators, especially in the field of biochemistry, and the control which the National Physical Laboratory suggests in regard to the calibration and hall-marking of such apparatus will receive the approval of all scientific men, while the proposed standardisation of scientific glassware may, it is hoped, come into force in the near future. This is a good record of work, and the National Physical Laboratory is an important national institution.

ANTHRAX AND NOTIFICATION.

ANTHRAX is one of the occupational diseases of which the occurrence must be notified to the Chief Inspector of Factories. Poisoning by phosphorus, mercury, arsenic, lead, and toxic jaundice are the others. The result of notification of these diseases has been remarkable. Industry has expanded rapidly, but the diseases have simultaneously contracted in the last 20 years. Phosphorus poisoning has disappeared; mercury and arsenic only linger to cause a few cases of illness each year; lead poisoning is restricted within an ever-narrowing circle; toxic jaundice, due to tetrachlorethane and trinitrotoluene, only raised its head during the war to be promptly throttled by a well-planned attack. Anthrax alone has maintained its toll of victims; but even here the number of cases in proportion to those exposed to risk is far smaller than of old; and it is no longer the scourge to the woollen industry which earned for it the name of woolsorters' disease. That industry has combined to fight it; and a scientific scheme for disinfecting all possibly infected wool as it is imported bids fair ere long to free the industry from its old enemy. Anthrax, however, affects other animal products besides wool, as was demonstrated by the outbreak which recently occurred in this country and in America from the use of shaving brushes made from infected foreign hair. Strict precautions are now enforced to ensure disinfection of all such materials. Foreign hides and skins are other sources from which infection may arise, and precautions have to be observed in handling them. But the anthrax bacillus seems almost uncanny in its capacity for eluding disinfection and precautions. It will sneak unsuspected on horsehair through a carpet factory and infect the hand of a carpet-layer; or gaining access to wall plaster, it will attack a paperhanger; or, as in the case referred to recently in the House of Commons, driven from factory premises, it will lurk in skins in a warehouse to which regulations do not apply. Nevertheless, notification betrays its twists and turns, and enables the cordon of precautions to be drawn ever tighter. Here we see the value of notification of disease at its best, for it is only of value when followed up, when research is embarked upon to discover means of prevention, and when those means are enforced. Notification only indicates the field for inquiry; it is no panacea in itself. Without investigation and compulsory precautions notification only alarms without giving confidence.

SPIROCHÆTAL HÆMOPTYSIS.

THERE is a growing tendency to attribute many of the symptoms occurring in the subjects of pulmonary consumption to the action of organisms other than the tubercle bacillus. In the May number of the *American Review of Tuberculosis* (Baltimore: National Association for the Study and Prevention of Tuberculosis) Dr. A. N. Sinclair gives prominence to the part played by Vincent's spirochæte in the provocation of hæmoptysis in cases of pulmonary tuberculosis. He found this micro-organism in a large proportion of cases, and it was present in 256 out of 410 cases of pulmonary tuberculosis. Of the 256 positive cases, 71 per cent. were complicated by hæmoptysis, whereas of the 154 negative cases only 36 per cent. were thus

¹ Investigations on Clinical Thermometry: Continuous and Quasi-Continuous Temperature Records in Man and Animals in Health and Disease. By G. Sims Woodhead, M.A., M.D., LL.D., professor of pathology, Cambridge; and P. C. Varrier-Jones, M.A., M.R.C.S., L.R.C.P., Foundation Scholar, St. John's College, Cambridge (From the Pathological Department, University of Cambridge). THE LANCET, Jan. 22nd, Feb. 5th, 12th, 26th, and March 4th, 1916.

complicated: He also found that out of 238 cases of hæmoptysis 182, or 76 per cent., harboured the spirochæte, whereas of the 172 cases without hæmoptysis only 74, or 43 per cent., harboured the spirochæte. Thus, the presence of Vincent's spirochæte in the sputum makes hæmoptysis a comparatively probable complication. The author also argues that in the treatment of hæmoptysis the presence of this micro-organism is an indication for special restriction of exercise and general freedom. His contentions will certainly stimulate others to examine tuberculous sputum for the presence of a mixed spirochætal infection.

TARTAR EMETIC IN SURRA.

THE Agricultural Research Institute at Pusa has issued a bulletin dealing with the treatment of surra in camels by intravenous injection of tartar emetic. The author of the pamphlet is Mr. H. E. Cross, M.R.C.V.S., described as camel specialist at Sohawa, Punjab. Surra is a very fatal disease among camels, due to infection with trypanosomes. Mr. Cross, who has conducted a number of valuable investigations into other diseases of camels, injected six camels suffering from surra with a 1 per cent. solution of tartar emetic, and four of them were cured. Great care was taken to ensure the solution entering the vein, since in camels, as in human subjects, sloughing is liable to ensue if any of the solution passes into the subcutaneous tissues. The fluid was injected slowly at blood temperature. Mr. Cross found that 600 c.cm. of the solution could be given in the day if divided into three injections spaced out at 2-3 hour intervals. In four of the six camels treated no trypanosomes appeared in the blood after the injections.

METROPOLITAN WATER BOARD RESEARCHES.

WE have received the thirteenth research report issued by the authority of the Metropolitan Water Board from the chemical and bacteriological laboratories under the control of Sir Alexander Houston, Director of Examinations to the Board. An outstanding feature of this report is the study that has been given to the question of rapid filtration. This suggestion of speeding up is described as a contentious but most important subject, and by rapid filtration, we are told, is meant any apparatus, installation, or process, which filters at a much faster rate than is found in connexion with slow sand filters in which "washing" is effected by mechanical means. Without entering into the details of the process, except to say that it involves usually the use of a coagulant—e.g., aluminium sulphate—we may briefly refer to Sir Alexander Houston's opinion on the subject, which is, to speak generally, that in cases when a water is epidemiologically satisfactory but highly coloured, as in the case of moorland supplies, rapid filtration with the use of a coagulant achieves the most satisfactory results. He makes, however, important reservations, and asks whether it is permissible to filter stored water so rapidly, for though it may lead to material economic gain and the saving of filtration area, it is well established that ante-filtration or post-filtration sterilisation processes produce a water which is epidemiologically safe, innocuous, tasteless, and reasonably satisfactory from a physical and sentimental standpoint. The suggestion seems to be that so far rapid filtration has not the evidence of experience behind it in regard to safety for the water-consuming public, though it might be combined with a chlorination process without adding seriously to the expense of treatment. The proposed changes in treating our raw water-supplies need to be very carefully studied lest any innovation is introduced at the price of health. The results of chemical analysis are, at all events, shown to be less satisfactory obtained with rapid filtration than with slow sand percolation, and the bacteriological results are not encouraging. Security, however, seems to reside in a chlorination process added to old-time procedure, and Sir Alexander Houston states that it is debatable whether the policy of substituting in connexion with

new works a less expensive rapid for a more costly slow sand-filtration process is sound. The point has evidently arisen out of the increased demand of labour and cost of working materials. The use of chlorine has led to the nuisance of evil taste, but this bids fair to be overcome, while an interesting outcome of the water laboratory researches has been that when filtration has proved unsatisfactory this has been shown to be due not to floods, but to a seasonal development of diatoms governed by bright weather and temperature. The report is most interesting, and contains an admirable series of reproductions of photographs of deposits from raw and filtered supplies, demonstrating the efficiency or discrepancies of the filtration processes.

HEREDITARY SPASTIC PARAPLEGIA.

Dr. V. R. Mason and Dr. W. F. Rienhoff, jun.,¹ of the Medical Clinic, Johns Hopkins Hospital, report four cases of the rare hereditary disease of the central nervous system known as hereditary spastic paraplegia which affected members of one family for three generations. The condition was first described by Strümpell, who reported two cases in 1880, and a few years later was able to demonstrate the pathological basis of the syndrome. Since then the records of about 60 affected families have been published. The malady usually affects individuals in only one generation, but in seven of the families recorded characteristic symptoms were present in more than two generations. Etiological factors, other than heredity, are not known. The symptoms may become manifest at any age, although it is characteristic of hereditary diseases of the central nervous system that the age of onset is about the same in individuals of the same generation. There is no evidence that sex plays an important rôle either in the occurrence or the transmission of the disease. The fundamental symptoms from which the disease derives its name is a spastic paraparesis which may involve the upper extremities to some extent after the condition has progressed for many years. The most important subsidiary symptoms are tremor of the tongue, as a rule intentional in type, disturbances of speech, optic atrophy, nystagmus, ocular palsies, bulbar disturbances, scoliosis, pes equinovarus, ataxia, muscular atrophies, and occasionally some mental impairment. Sensation and the sphincter functions are usually unaffected. The condition closely resembles both Marie's and Friedreich's hereditary ataxia in its aetiology and pathological anatomy. All three diseases begin usually about puberty, progress slowly to a certain point, and then become stationary. Moreover, typical or pure cases of any of the three affections are rare. Symptoms common to all three diseases have been observed, such as nystagmus, tremor, and pes equinovarus. In each disease there is a marked combined sclerosis of the postero-lateral tracts of the cord of the type characteristic of hereditary disease of the nervous system. The differential diagnosis is in some cases impossible, but in the majority the presence or absence of paraplegia, or ataxia, is distinctive.

EMBOLIC ANEURYSM OF PERIPHERAL ARTERIES.

EMBOLIC aneurysm of peripheral arteries is rare. In the *Glasgow Medical Journal* Mr. Douglas K. Adams has reported two cases which, by a curious coincidence, occurred in the same wards within a month of one another. In the first case the patient was a metal-polisher, aged 29 years. He was admitted on Dec. 3rd, 1919, complaining of dyspnoea of four years' duration. For some years he had "rheumatic pains in the legs" and the ankles occasionally swelled. On admission he was found to be poorly nourished and pale. The fingers were clubbed. The apex beat was in the fifth interspace an inch outside the nipple line, and cardiac dullness extended half an inch to the right of the sternum and to the upper border of the third rib. A soft blowing mitral systolic murmur was heard, and a

¹ Bulletin of the Johns Hopkins Hospital, June, 1920.

rough aortic systolic. The second aortic sound was almost replaced by a soft diastolic murmur. The pulse was of the water-hammer type. Over the lungs the percussion note was slightly impaired, especially at the bases, and râles were heard at the left base. On Dec. 10th the lower border of the liver was found palpable, and he complained of generalised rheumatic pains, but the temperature had not risen. Aspirin and sodium salicylate seemed to give relief. On the 16th he complained of pains radiating from the buttock into the left thigh, and on the 23rd a swelling of the size of a hen's egg developed between the great trochanter and posterior superior iliac spine. It was fluctuant and pulsatile. A blood culture was negative. Embolic aneurysm of the gluteal artery, due to ulcerative endocarditis, was diagnosed. The posterior division of the left internal iliac artery was ligatured and the swelling disappeared. After the operation the patient was troubled with vomiting, abdominal distension, and pain, and also with pains in the chest and dyspnoea. The pulse became irregular and fast, and he died on Jan. 3rd, 1920, from cardiac failure. At the necropsy the pericardium was found thickened and opaque, with fibrinous exudate on its surface. The heart was much enlarged, there being great hypertrophy of the ventricles. Both mitral and aortic valves bore numerous vegetations, some apparently recent. The root of the aorta showed signs of sclerosis, with some calcareous deposit. The lungs were adherent to the chest wall and diaphragm. On the left gluteal artery there was an aneurysm of the size of a hen's egg, containing laminated clot. In the second case the patient, a chauffeur, aged 33 years, was admitted on Jan. 30th, 1920. He complained of loss of power in the left arm and leg of three months' duration, which began suddenly in November, 1919. He had been a soldier for 15 years and contracted malaria and dysentery in India in 1906. He had an attack of "rheumatism" in May, 1915, and of pleurisy in France in October, 1918. Otherwise his health had been uniformly good. On admission he was well nourished but anæmic. The apex beat was in the fifth interspace just outside the nipple line and was diffuse and heaving, with a presystolic thrill. Cardiac dullness extended to the upper border of the third rib, the right sternal margin and three-quarters of an inch outside the left nipple line. The percussion note was slightly impaired over the manubrium. There were a loud mitral systolic murmur and a rough diastolic. At the aortic cartilage was heard a rough systolic murmur and the second sound was replaced by a soft blowing murmur. The arteries were somewhat thickened. The pulse was 96 and regular, but "water-hammer." There were left spastic hemiplegia with extensor response and paresis of the face. After a few days enlargement of the liver was noted. There was effusion into the left knee-joint. The temperature rose to 100° F. On Feb. 12th he complained of severe pain in the right arm, and paralysis of ulnar distribution with wasting of thenar and hypothenar eminences was noted. In the middle of the forearm towards the ulnar side a pulsatile swelling was found. Mr. R. B. Carslaw operated under local anaesthesia and found a fusiform aneurysm of the right ulnar artery to the sheath of which the ulnar nerve was adherent. As the general condition was unsatisfactory the artery was ligatured proximally and distally. Death occurred a few days later from failing heart. It is noteworthy that in both cases there was a rheumatic history and the blood culture was negative. Irving Simons,¹ in a review of bacterial endocarditis, gives a list of the recorded cases of embolic aneurysms. These include sciatic artery (one), ulnar artery (one), femoral artery (two cases) and popliteal artery (one).

¹ Quarterly Journal of Medicine, April, 1914.

BRIGHTON AND JUVENILE WELFARE.—The Brighton and Hove Council for Juvenile Welfare has decided to appoint a whole-time paid organiser at £350 per annum. Both municipal education authorities have voted a grant of £150 towards the work. The problem of juvenile crime is as difficult to face in Brighton as elsewhere, and the efforts of the council merit attention and support.

NATIONAL HEALTH INSURANCE: SOME DEFECTS IN MEDICAL ADMINISTRATION AND THEIR REMEDIES.

A MEMORANDUM on some of the medical aspects of the National Health Insurance Act, drawn up by Sir James Mackenzie and the staff of the St. Andrews Institute for Clinical Research, has been issued as an appendix to the report of the Inter-Departmental Committee appointed to consider and report upon the form of medical record to be prescribed under the terms of service of insurance practitioners contained in the Medical Benefit Regulations for 1920. On the general aspects of this report we commented in a leading article last week. The memorandum has been drawn up with a view to indicate the principal defects in medical knowledge which exist at the present time and which impair the success of the Act, and also to indicate some steps which can be taken to remedy them.

Defects in Medical Knowledge.

1. *Diagnosis, especially of the early stages of disease.*—There is an idea current that diagnosis in the majority of cases is so simple that little difficulty should be found in recognising from the patient's symptoms the nature of the disease from which he suffers, and scheduling it under a definite classification. This is required for a variety of purposes, such as army statistics, club certificates, the Insurance Act, death certificates. Such diagnoses are, for the most, imperfect, and statistics based upon them are misleading, because the classification of disease is at present based largely upon morbid changes which have been discovered and studied after death.

The reason for this is that at one stage of medical history morbid anatomy held sway, and the obviousness of certain morbid changes discovered after death led to the belief that these changes indicated the real nature of disease. It was not recognised that many of these morbid changes were merely the terminal stages of a long preceding illness, and that during most of the time such structural changes were not necessarily present. The classification of the morbid anatomist was largely adopted by the physicians, who diligently sought (in the living) for the "physical signs" in order to correlate the signs during life with the morbid state found at death. In consequence of this attitude the present classification of disease in the living has been based upon the morbid anatomy of the dead, and has led to the conception that each individual's ailment can be classified according to a gross pathological and structural change.

The incompleteness of medical knowledge at the present time is clearly shown by the fact that a very large number of patients who consult their doctor and who are incapacitated from work do not suffer from any disease referable to the current classification, or one which can be detected by physical signs. They suffer from disabling symptoms not referable to the disease of any special organ. The cause of such symptoms is frequently unknown, and they therefore cannot be rationally treated. It is only in the advanced cases or in the acute infections that a diagnosis can be made in accordance with text-book descriptions. The majority of patients present few or no physical signs, and these may be mostly referable and due to the disturbance of organs not themselves the primary seat of disease.

The chief signs of the early stage of disease are the complaints of the patients called forth by some distressful sensation. The tendency has been, in the absence of physical signs of disease, to take the more prominent symptom or sensation and consider it to be the disease, and the object to which treatment should be directed, as neuralgia, dyspepsia, anæmia, palpitation, neurasthenia, &c. The use of terms such as these indicates nothing more than the presence of a symptom.

Careful inquiry shows that in the majority of such cases a number of other sensations or symptoms are present, referable to other organs of the body. For example, the patient may complain of palpitation. Inquiry will reveal other symptoms referable to the stomach and intestine, to the nervous and to the muscular systems. When these symptoms are gathered together they are found to show a disturbance of so many different organs that the conclusion is forced that there is a common cause which upsets the balance of the different organs and systems. In some cases the cause can be recognised and dealt with, as in the case of some localised infection, such as an abscess. In most cases, though a single cause of the widespread disturbance can be inferred, it is not possible to identify it.

Many of these causes are transient and are thrown off, as is the case in the trivial ailments which cause a temporary

incapacity. In other cases it would appear that the persistence of such a cause which at first merely impairs the functional activity of an organ may ultimately lead to morbid changes in structure, such as arterial disease, certain diseases of the heart, kidney, and stomach. If these earlier symptoms of disease are to be unravelled, it is necessary that the panel doctor should not be tied down to a diagnosis made in the terms of text-book medicine, and further, that he should be encouraged, for his own advancement in knowledge, to keep a record of each individual case, however trivial it may appear to be.

These records will at first be of little value for statistical purposes, but by forming a continuous medical history of each individual they will enable the earlier symptoms to be correlated with any disease which may develop later. In this way the knowledge at present wanting may be supplied. Recognising this defect in medical knowledge the doctor should not be requested to specify the nature of a patient's illness either in the routine records or when certifying his incapacity for work, unless the doctor recognises with fair certainty the disease from which he suffers. In a large number of cases this cannot be done, and for a doctor to make a practice of giving a name to a complaint in cases where he knows this to be impossible, is not only illogical, but demoralising, and inimical to that clearness of thought which is necessary for that recognition of the defects in knowledge which is the first step to remedy these defects. Where certifying in such cases a patient's unfitness for work, the mere statement that he is unfit should suffice with a reference to the principal facts observed. If further information be needed in particular cases the card index described below will afford it.

In place of the method at present employed for the recording of the patient's complaints we suggest that a system of index cards should be established which should be used in such a way that certain simple but essential facts are recorded, and that these cards should be available for reference both for administrative purposes and still more for tracing the history of the patient's ill-health.

It is not assumed that this method will at once be successfully employed. At first, many of these records will be so badly done that they will be useless, but some will be carefully done, and as the doctors become more experienced their value will constantly increase. If the suggestion given later be adopted, that students before graduation are instructed in the duties peculiar to panel doctors, these records will become of the greatest value, not only for the practitioner himself in his treatment of the case, but also towards building up new material of medical knowledge. The following plan for the observation and recording of the ailments of patients has been worked out at the St. Andrew's Clinical Institute, and is used by the panel doctors there, and we suggest that an explanatory notice in the following form should be sent to every doctor, and that cards should be supplied to him on the lines there indicated.

[Instructions for the recording of cases.]—Doctors are requested to make a brief note of each patient. The purpose is to keep a record indicating the nature of the complaint. This record will be of value for reference in future illnesses, and will lay a basis for the detection of the early signs of disease. Further notes, added as the case progresses, will be of use in this way, and will also become a record of the effects of treatment.

If the doctor is interested in some disease, these records can be made fuller. The proposed method is provisional, and the Committee would be obliged if individual doctors would send their suggestions for such modifications as would render the method more useful.

Name.	Age.	Occupation.
Chief complaint.		
Associated sensations.		
Physical signs.		
Provisional diagnosis.		
Treatment.		
After-history.		

These records should be retained by the doctor, and, in cases of patients who transfer, the Insurance Committee should arrange for the transference of these case cards.]

2. *Defective knowledge of drugs.*—The administration of the Insurance Act involves a large expenditure for drugs, and it behoves legislators to have clearly in mind the present state of knowledge in regard to their use. An inquiry will reveal that there is no accurate knowledge as to the effect of a great many remedies, with the result that worthless drugs are given in the belief that they possess certain properties. A careful inquiry will often reveal that many drugs do not possess the properties attributed to them. Indeed, such an inquiry would reveal the uselessness of so many remedies that the money spent upon them is quite unjustified.

There are two difficulties which will for a long time hamper an intelligent therapy: First, the belief of the people that for each ailment a drug or remedy of some kind exists, and the natural desire that something should be given or done. The second difficulty is the belief of the doctor in the efficacy of his remedy. While the real cause of disease is hidden, and its removal therefore impossible, treatment will continue to be directed towards signs and symptoms. As no rational system of instruction in therapeutics is given

in the schools, or can be given until the nature of disease and the action of drugs is understood, the doctor is driven for help to an empiric experience, guided often by the statements of the advertising chemist.

These difficulties should be recognised, and while they cannot at present be fully combated, a constant endeavour should be made to place therapeutics on a surer basis. This can be done by the encouragement of research, particularly amongst the panel doctors themselves. Most valuable help, no doubt, has come from the experimental pharmacologist, but what has never been sufficiently recognised is that the action of remedies on healthy organs is often different from that on the impaired or diseased organ. This has been clearly brought out in the case of the heart. For many years large numbers of observations, experimental and clinical, had been made to find out the action of drugs of the digitalis group on the human heart. It was not until it was recognised that such drugs acted in a different manner on the diseased heart from what they did on the normal heart that the form of heart disease in which they were of benefit could be clearly recognised, so that now they can be administered with precision to suitable cases, and withheld in the great number of cases in which they had been given hitherto.

The intelligent recognition of symptoms enables the doctor to watch the effects of his remedies, and as he is the individual who has the best opportunity, his services are necessary to the intelligent prosecution of this research. An arrangement by which his opportunities should be related to the laboratory investigator and hospital physician would render it possible to lay the basis for a rational pharmacopœia. This is no visionary suggestion, but one which has already been carried out on a limited scale with gratifying success.

As the vast number of panel doctors cannot undertake themselves such an inquiry, it is suggested that certain investigators should specially study those remedies most in vogue with the panel doctors, and after each drug has been carefully studied and its properties understood, and the cases suitable and unsuitable for its use have been determined, a short note, such as the following, conveying this information should be sent to each panel doctor:—

[The use of digitalis.]—Digitalis is only of use in those cases of heart failure where the exhaustion of the heart is due to an excessive rate. It acts by slowing the rate, so that each beat is more efficient. There are only a few forms of increased rate in which it has this effect: when the heart's rhythm is regular and normal and the increased rate is due to some exciting agent, as fever, digitalis is practically without effect. Its use is specially indicated where the heart's rhythm is irregular as well as rapid, especially in the condition due to auricular fibrillation. Here the irregularity is very disorderly, small and big beats occurring with no kind of orderly sequence.

In such cases the drug should be given in full doses, and pushed till an effect is produced, the effect being a marked decrease in the heart's rate, nausea, or diarrhoea, or a sense of oppression across the chest. When these signs appear the drug should be stopped. If the heart's rate has decreased the drug should be given when the rate begins to increase in just sufficient amount to keep the rate between 70 and 80. If there is no decrease in the rate, but nausea, &c., then the drug should not be resumed. The tincture is the most serviceable form. It should be given to the adult in doses of 15-20 m., so that one drachm is taken in one day. The effect may be looked for in from four to seven days.]

The detailed results of these investigations should be published so that the reasons for the conclusion should be available. In this way there would be gradually built up a pharmacopœia of practical value.

3. *Defective knowledge of prognosis.*—A problem which constantly confronts a doctor, and one which is of the greatest importance in the working of the Act, is to assess the condition of the patient in relation to (1) his capacity for work, and (2) his future history.

(1) The present great deficiency of this knowledge was demonstrated during the war, when it was clearly shown that the knowledge did not exist which would enable doctors to classify men according to their capacity for work. It is manifest that, as the panel doctor has to certify a man's capacity or incapacity for work, there is urgent need for this kind of knowledge. The information necessary can only be gained from the systematic observation and examination of a large number of individuals carrying on their usual occupation, and this can only be done by the general practitioner, whose occupation provides the opportunities for systematic observation of this kind. The need for this kind of knowledge is forced upon every panel doctor. He has to decide whether a man is fit for his work. He may have to recommend him to receive sick pay, and he often has to determine whether the patient's occupation is detrimental to the health. It will be seen that his decisions involve the expenditure of large sums of money, and may influence the kind of life and occupation that many must follow.

(2) This misapprehension of the significance of signs and symptoms leads directly to much useless expenditure of money and the unnecessary interference with a man's work. This is particularly shown in the detection of some common

sign, as a cardiac murmur or albumin in the urine, medical knowledge not yet having advanced so far as to be able to recognise the significance of these signs, with the result that many healthy people are thrown on the sick list.

Investigations to remedy this defect should be undertaken by the general practitioner, as he is the only person who has the necessary opportunity. Steps should be taken to give facilities and instruction to such as are desirous to help in this matter. At the St. Andrew's Institute, investigations with this object are being carried out along the lines indicated, and it is proposed to collaborate with other doctors in this investigation. We suggest that from time to time brief notes of the results which are being obtained should be issued. The following is an example of the information which should from time to time be issued upon the prognostic significance of special symptoms.

[*The significance of systolic murmurs.*—It should be understood that the healthy heart can exhibit murmurs which are physiological in origin or are of so slight significance as to be negligible so far as the efficiency of the heart is concerned. These murmurs are always systolic in time and heard loudest at the apex, mid-sternum, or base of the heart. If the person can undertake such effort as we recognise to be compatible with his age without experiencing any distress (breathlessness or pain), and if the heart be normal in size or only slightly enlarged, then, for all practical purposes, the cause of the murmurs has nothing to do with any incapacity from which he may suffer.

If in response to effort the patient becomes exhausted, without breathlessness or cardiac pain, then the cause of his ill-health is not primarily cardiac, for exhaustion is not a sign provoked by a failing heart.]

The Teaching of the General Practitioner.

It is a remarkable fact that though the vast majority of medical students become general practitioners no attempt is made to teach them how to make use of their opportunities in general practice, and no hint is ever given them that the phases of disease which they will meet will be different from that which they have seen in the hospitals. There is an urgent need for a definite course of teaching and training students in their last year how they should conduct their practices as panel doctors. If there was a scheme by which they could learn how to question a patient intelligently, how to make short but accurate notes, how to watch the patient as he passes from one phase of disease to another, the working of the Insurance Act would, year by year, be greatly facilitated, while a great impetus would be given to the investigation of these dark fields of medicine which only the general practitioner can explore.

Central Clinics.

The recognition of the great defects in medical knowledge to which reference has been made—viz., diagnosis treatment, and prognosis—has led to the putting into effect a scheme to make good these defects. As it has also been recognised that these defects cannot be made good without the aid of the general practitioner, the basis of the scheme is to train him to make use of the opportunities which he and he alone possesses. It was also recognised that this object could be combined with means for affording the panel doctor facilities for the better carrying out of his duties towards his patients.

A building was therefore secured in which investigations could be carried on by the trained general practitioner, in association with the laboratory facilities for bacteriology, chemistry, and X rays. While each general practitioner examined his own patients, each one made a more particular study of a special subject, one, for instance, making himself familiar with the diseases of the nervous system, another with disease of the circulatory system, and so forth.

The system of specialisation at present prevalent enables the specialist only to see disease at a late stage. Moreover, as in ill-health there are reactions affecting several organs or systems, a man who restricts himself to the study of but one organ or system cannot acquire the power of detecting the primary cause of the patient's ill-health. We recognise that a general practitioner who makes a special study of the diseases of one organ or system is better qualified in that he has a wider experience, and can therefore take a broader outlook of his patient's complaint, besides having an opportunity for seeing the disease at an early stage.

In the St. Andrews Institute each panel doctor has a room, and arrangements are made for him to see his panel patients there. He has the use of the laboratories, and he can call upon his colleagues and consult with them on those cases of which they have made a special study. The great advantage of such a scheme is manifest. It is practicable, and the idea can be extended so that all the different health authorities could be in the same building and the facilities of one branch could be used by the other branches.

Methods Pursued at the St. Andrews Institute for Clinical Research.

1. Each clinician has a private room in the institute. This is reserved from 11 to 1 on Mondays, Wednesdays, and Thursdays for research cases. During the rest of the day each practitioner may use his private room as a private consulting-room. Two panel practitioners have adopted this plan for all their patients. They have thus the advantage of the use of the scientific departments

whenever required. An index file and cards are provided in each room upon which brief notes are kept of each private or panel patient. These cards will, in time, form records of the life-history of each patient. In the event of a patient removing to another district these notes can be sent to his new attendant.

2. Cases for research are selected from his own practice by each member of the clinical staff. These are, in the first instance, seen by him, and he is at liberty to consult Sir James Mackenzie or any colleague at any stage of the case. If any special investigations are required, these are carried out by the staff of the special departments.

3. On Tuesday afternoons some special subject, arranged beforehand, is discussed by a general meeting of all members of staff.

4. On Friday afternoons the whole staff discuss the cases seen during the week, and any suggestions for investigation of any case made at that meeting are proceeded with and added to the record.

Summary.

1. The present phase of medical knowledge is defective, because the classification of disease is largely based upon pathological changes discovered after death, which bear little or no relation to the clinical manifestations of ill-health and no relation to the early symptoms of disease which occur before structural changes can be recognised.

2. Advance in knowledge along the right lines can only be effected by making use of the opportunities of the panel doctor.

3. Encouragement must be given to the panel doctor to make use of his opportunities for improving medical knowledge by: (a) Encouraging him to keep brief records of his cases and of the symptoms presented on the lines indicated; of the effect of treatment upon them, and of the continuous history of his cases. (b) By issuing to him from time to time notes upon the mechanism and the significance of symptoms.

4. By improvements in medical education in affording some instruction on clinical medicine as studied and treated in general practice as apart from its study under hospital conditions.

5. In view of notes of cases kept by a practitioner as indicated, certificates of fitness or unfitness for work should be accepted apart from a definite diagnosis in the numerous cases in which a true diagnosis is not as yet attainable.

6. By the coördination of workers, clinical and laboratory, the progress of medicine can be favoured, and the more skilful treatment of panel patients facilitated.

URBAN VITAL STATISTICS.

(Week ended July 31st, 1920.)

English and Welsh Towns.—In the 96 English and Welsh towns, with an aggregate civil population estimated at nearly 13 million persons, the annual rate of mortality, which had been 9.9, 9.9, and 9.8 in the three preceding weeks, was again 9.9 per 1000. In London, with a population of nearly 4½ million persons, the annual death-rate was 9.5, or 0.4 per 1000 above that recorded in the previous week, while among the remaining towns the rates ranged from 2.9 in Edmonton, 3.8 in Carlisle, and 5.2 in Lincoln, to 15.4 in Blackpool, 16.1 in Barnsley, and 16.8 in South Shields. The principal epidemic diseases caused 199 deaths, which corresponded to an annual rate of 0.6 per 1000, and comprised 90 from infantile diarrhoea, 37 from diphtheria, 33 from measles, 24 from whooping-cough, 9 from scarlet fever, and 6 from enteric fever. Measles caused a death-rate of 1.6 in Middlesbrough, but the mortality from the remaining diseases showed no marked excess in any of the towns. There were 1956 cases of scarlet fever and 1481 of diphtheria under treatment in the Metropolitan Asylums Hospitals and the London Fever Hospital, against 1911 and 1556 respectively at the end of the previous week. The causes of 23 of the deaths in the 96 towns were uncertified, of which 4 were registered in Birmingham and 3 in South Shields.

Scotch Towns.—In the 16 largest Scotch towns, with an aggregate population estimated at nearly 2½ million persons, the annual rate of mortality, which had been 12.1, 11.1, and 11.6 in the three preceding weeks, fell to 11.2 per 1000. The 235 deaths in Glasgow corresponded to an annual rate of 11.0 per 1000, and included 13 from small-pox, 6 from infantile diarrhoea, 2 from whooping-cough, and 1 each from measles, scarlet fever, and diphtheria. The 54 deaths in Edinburgh were equal to a rate of 8.3 per 1000.

Irish Towns.—The 107 deaths in Dublin corresponded to an annual rate of 13.4, or 0.6 per 1000 above that recorded in the previous week, and included 3 each from whooping-cough and from infantile diarrhoea and 1 each from measles and from scarlet fever. The 104 deaths in Belfast were equal to a rate of 13.1 per 1000, and included 4 from infantile diarrhoea.

THE ROYAL SANITARY INSTITUTE:

BIRMINGHAM CONGRESS, JULY 19TH-24TH.

LAST week we briefly reported the Sections of Preventive Medicine and of the Hygiene of Child Welfare, and we return now to an important discussion on

INDUSTRIAL EFFICIENCY AND FATIGUE,

which took place on Tuesday, July 20th, in the *Section of Industrial Hygiene*.

Three factors are coming to be recognised as fundamental in relation to the future development of medicine in this country: one is, that prevention is more important than cure; the second, that over-fatigue is the most potent influence conducing to ill-being, lowered resistance, and final breakdown; the third, that our national life is essentially based on industry, which is ever drawing into its net an increasing proportion of the population, male and female.

Mr. NEVILLE CHAMBERLAIN, as President of the section, in an inaugural address, gave an admirable and condensed sketch of the rise of industrialism and of the rank weeds of long hours and of the exploitation of child labour which sprang up alongside the good seeds of labour-saving devices and threatened almost to ruin the harvest. The lurid light of those early stages of development is now sinking into obscurity as the laws underlying human efficiency are coming to be known.

Professor E. L. COLLIS, a member of the Industrial Fatigue Board, summarised the position of knowledge to-day. He pointed out that, while the human body may be considered as a machine which requires fuel in the form of food to enable it to perform work, it is a living machine, the structure of which is in a constant state of metabolic activity, building itself up and breaking itself down; that the internal activity of building up—so-called rest—is a direct incentive to the external activity of breaking down or work; that work is even more necessary to health than rest; that fatigue, the result of sufficient work, is a healthy phenomenon, the forerunner of healthy rest; but that without sufficient rest over-fatigue results which manifests its presence as ill-being, physical and mental—a lowered capacity for work and for resisting sickness, associated with bad temper and discontent. Physical work which is performed by the muscles is directed by the brain; both muscular and mental activity steadily increase with practice which, if uncontrolled, would bring the organism to a state of excessive exhaustion. This state is guarded against by the mechanism which transmits messages to the muscles; here, in the synapse in the spinal cord through which the efferent impulses must pass, a block arises; the coming into existence of this block (while both muscular and mental activity may be increasing through practice) constitutes the onset of fatigue. Over-fatigue lowers industrial efficiency and the standard of well-being; thus the objectives of maximum production and maintained health depend on its avoidance. The interests of national productivity and of national health are in this matter the same—the avoidance of over-fatigue. When output is increasing hour by hour during the day, and day by day throughout the week, there can be no accumulation of fatigue; ill-health is then kept at arm's length. When output is falling off as the day lengthens, and as the week progresses, fatigue is accumulating, *joie de vivre* is diminishing, discontent is appearing. Much could be done to improve efficiency and prevent over-fatigue. Labour turnover, an economic waste which in factory employment alone places upon industry a yearly burden of some 40 million pounds, due to the rolling stones of labour trying to find round holes to fit into, is productive of much unnecessary inefficiency and over-fatigue. It can easily be reduced 70 per cent. and probably more by medical and psychological selection of workers for work, instead of adhering to haphazard, come-and-go-as-you-like methods of engagement by trial and error. Workers should be fitted to their work; taught their work; clothed for their work; provided

with suitable food and stimulated to personal hygiene. Work should be fitted to the worker: ventilation made effective; lighting made adequate; tables, benches, tools and machines constructed to suit each worker; periods of work and of rest scientifically planned. What is required is a right understanding of work in relation to the human machine, and attention to this machine, its possibilities and reactions, its medical and psychological aspects. Then well-being and contentment, skill, and production will be increased, while chronic fatigue and discontent, inefficiency and poverty will be decreased.

Welfare Work in Industry.

Miss A. M. ANDERSON, Principal Lady Inspector of Factories, next dwelt on the progress which is being made, and pointed out how the newer welfare movement is a co-ordinated effort to improve the personal health and life of the industrial worker, an effort directed by Government orders based on scientific research. A new science and art of labour, and of its management, is coming to light, aimed at securing health and welfare in the workplace, and quantity and quality in output; aims rendered possible by "fearless work and hopeful rest," the result of whole-hearted co-operation between capital and labour. Here is hope for a true international, an international of industry; and it may be noted that in the field of research this era is dawning, for the Comité d'Hygiène of France, the American Committee on Fatigue, and our own Research Board are in close touch, M. Langlois and Professor Lee both attending a recent meeting of the board in London. Hippocrates said the art of healing and the "love of man"—the whole welfare of humanity—are identical. Here the nations can gather in amity in pursuit of investigations into humanity aimed at saving fatigue, lightening labour, ensuring safety, rendering first-aid, and ameliorating social conditions. Thus morbidity and premature mortality, bred of over-fatigue and sloth, will give way to health, the child of work and rest.

Mr. W. B. WELCH, welfare supervisor at Birmingham Small Arms Company, contributed a short paper of great interest not only for its contents but as being an instance of the useful work which can be done at individual factories by those possessing the spirit of inquiry. In particular he gave data which showed that the effect of gymnasium work on growing lads was to increase their stature by the time they reached the age of 18 by $3\frac{1}{2}$ inches, their weight by 14 lb., and their chest expansion by $1\frac{1}{4}$ inches; and also that the tendency among boys to stay in employment, rather than to move on, increased with age from 14 to 18.

Other papers were also read, one by Dr. W. A. DALEY dealt with the physique and working capacity of Liverpool dock labourers, and another by Surgeon-Commander R. J. MACKEOWN was devoted to the health of seamen and the need for safeguarding it.

Three papers of particular medical interest read in other sections merit further notice.

PROTECTIVE VACCINES IN INFLUENZA.

In the *Section of Preventive Medicine* Dr. W. H. WYNN read a paper on the Use of Vaccines for the Prophylaxis and Treatment of Influenza. The true value of vaccines for prophylaxis against epidemic influenza cannot, he said, be established until the morbidity of a large sample of the population, inoculated before an outbreak, as compared with that in uninoculated controls is submitted to expert statistical treatment. At present there is no agreement between bacteriologists as to the true virus of influenza, and the use of a vaccine is necessarily empirical, but there is general consensus that a vaccine for prophylaxis or treatment should contain several strains of Pfeiffer's bacillus, pneumococci and streptococci. Lasting immunity requires large doses, but such doses may produce unpleasant local or general reactions. These are relatively unimportant when occurring in selected individuals or groups of individuals, such as soldiers, who can rest for a day or two after an injection. The production of a long period of immunity outweighs the trifling disadvantages. But when, as with influenza, it is desirable to protect as

many as possible of the general population, unpleasant reactions, if possible, should be avoided. Immunity during an epidemic period of a few months only is aimed at, and this may be obtained with smaller doses, which will not produce reactions sufficient to interfere with work. Where, however, reactions are not objected to, it would be wiser to give the larger doses. Improvements in the manufacture of the vaccine may, in the future, enable large doses to be given without discomfort, and the experience with vaccine suspended in oil is suggestive of this possibility.

Author's Experience.

Dr. Wynn's own preference has been for a vaccine containing equal numbers of influenza bacilli, pneumococci and streptococci of several strains, and, so far as possible, from primary cultures. At first he gave 100 millions of each as a first dose, followed by 200 millions in seven days, but he now advocates a first dose of 200 millions and a second of 400 millions. In several instances a third dose of 800 millions and a fourth of 1200 millions have been used. By giving three or four increasing doses there is less reaction than by giving two large doses, and the final dose is the same.

"Over 1000 persons were injected with this vaccine, and I have a record of the result in 680. Of these, only 14 developed influenza, 4 of these only after three months. In all, the disease was mild, and there was no pneumonia. With most of these it is unfortunately impossible to compare them with uninoculated controls. The vaccine was used by many doctors under various circumstances. A common practice was to inject all the other members of a household in which there was a case of influenza. In one village there were two large preparatory schools. In one no vaccine was used, and nearly every boy, master, and servant suffered from influenza. In the other, 75 boys and 38 adults were injected. All escaped except one master, who was injected after infection had occurred. In the village, in which influenza was very prevalent, 31 adults and 16 children were injected and all escaped. At one hospital 117 nurses and maids out of 170 were injected in the autumn of 1918, at the beginning of the outbreak. Of the 53 uninoculated, 25 had mild attacks in the previous June, and all escaped subsequent infection during the autumn epidemic. Of the 28 presumably unprotected, 14 suffered from influenza, 2 having severe broncho-pneumonia, and 1 died. Of the 117 injected, 112 had two injections and 5 only one. Of the 112, 2 had mild attacks. Of the 5, 1 had a mild attack and 1 severe broncho-pneumonia."

American Experience.

Dr. Wynn went on to summarise the experience of protective inoculation in America, where it was practised on a large scale. Rosenow used a vaccine with the formula—pneumococci, 3000 mill. (type 1, 1500; type 2, 2750; type 3, 3500; type 4, 1250); *B. influenza*, 500 mill.; staphylococcus, 500 mill.; *Streptococcus hemolyticus*, 1000 mill. in 1 c.cm.; $\frac{1}{2}$ c.cm. was given as a first dose, and then 1 c.cm. and 1.5 c.cm. at intervals of seven days. In institutions 8306 were injected three times and 9388 were uninoculated. The incidence of influenza among the inoculated was 31 per 1000 and among the uninoculated 200 per 1000. The incidence of pneumonia was 1.0 and 12.0 respectively. Among the general population 93,467 received three injections, the influenza incidence was 87.9 per 1000 and of pneumonia 4.4 per 1000, as compared with 281.8 and 21.0 per 1000 among the uninoculated. Taking all the results, the average mortality rate in the inoculated was one-fifth of that in the uninoculated.

Dr. Tonney, of the Department of Health, Chicago, using Rosenow's vaccine, reported that of 44,494 not vaccinated there were 1039 cases of influenza, with 95 pneumonias and 60 deaths. Of the 2584 vaccinated once there were 14 cases of influenza, but of 1636 receiving a second injection there were no cases. Among the vaccinated there were 3 cases of pneumonia, but no deaths.

Minaker and Irvine, in San Francisco, used a vaccine containing 5000 mill. influenza bacilli, 7000 mill. pneumococci (3000 mill. each of type 1 and 2, 1000 mill. of type 4), and 100 mill. *Streptococcus hemolyticus* per c.cm., 0.5, 0.8, and 1.0 c.cm. were given at three-day intervals. The final dose was, therefore, 12,100 mill. organisms. The results are set out in the following table. The civilians were inoculated before Oct. 16th, 1918, three weeks after the epidemic began, and before it reached its height, and the marines before Oct. 20th. The results are given up to Dec. 1st, when the

epidemic had subsided. The naval men were not injected until Nov. 15th.

	No.	Influenza.		Mortality	
		No. of cases	Per cent.	No.	Per cent.
Uninoculated—					
San Francisco and Oakland ...	625,000	33,065	5.3	3035	9.2
Mare Island Navy Yard ...	8,232	1,296	15.7	65	5.0
Nurses and attendants in hospitals	530	186	33.8	4	2.1
Los Angeles ...	600,000	9,124	1.5	612	6.6
Inoculated—					
San Francisco civilians ...	1,080	14	1.4	0	0.0
Marines at Mare Island ...	1,950	35	1.8	1	2.8
Hospital men on duty in influenza wards ...	270	9	3.5	1	11.0
Naval Camp, San Pedro ...	3,100	53	1.7	0	0.0

Sherman, using a vaccine very similar to the one I have advocated, gave prophylactic inoculations to 9000 employees in large works in Philadelphia at the beginning of the epidemic, and only 5 were reported to have contracted influenza. He also gives the reports from 39 doctors using the same vaccine; 41,260 persons received one to four injections. Of these 963 contracted influenza, with 23 deaths, making a mortality rate of 0.57 per 1000 inoculated, as compared with from 5 to 25 per 1000 inhabitants in various parts of the country among those not inoculated. Wood, medical director of the Willard Storage Battery Co., of Cleveland, immunised over 3000 persons at the beginning of the epidemic. Less than 1 per cent. contracted influenza, and none died.

Watters, of Massachusetts, used a vaccine containing *M. catarrhalis*, pneumococcus, and *Streptococcus hemolyticus*, of each 400 mill., *B. influenza* 100 mill. per c.cm.; 2 c.cm., 3 c.cm., and 4 c.cm. were given at three-day intervals. Of his laboratory staff of 14 10 received inoculations and all escaped; of the other 4, 2 had severe influenza. Public clinics were opened and inoculations given free of charge, and vaccine was sent to many boards of health and large works. Some of the results may be summarised as follows:—

	Number.	Influenza, per cent.	Influenza mortality, per cent.
H. P. Hood Milk Co.:—			
Not inoculated ...	300	31.0	4.3
Inoculated ...	247	6.8	0.0
Boston Confectionery Co.:—			
Not inoculated ...	200	30.0	2.7
Inoculated ...	250	0.8	0.0
F. H. Roberts Co.:—			
Not inoculated ...	339	2.7	11.0
Inoculated ...	329	0.9	0.0
Allentown State Hospital:—			
Not inoculated ...	575	32.4	17.7
Inoculated ...	722	8.4	15.1

Watters, combining all his records, including the above, found that the disease incidence among the inoculated was approximately 3.5 per cent., while at the same time among others not inoculated and under similar surroundings the incidence was 28 per cent. The only deaths among the inoculated were among patients in the Allentown State Hospital, and of the 8 deaths 3 patients had only received one injection, and 3 only 2.

The Ministry of Health Vaccine.

In England Dr. Wynn considers there has been an unnecessary fear of large doses, and the formula originated by the War Office Conference contained only 60 mill. *B. influenza*, 80 mill. streptococci, and 200 mill. pneumococci in 1 c.cm., and it was advised that $\frac{1}{2}$ c.cm. be given as a first dose, followed by 1 c.cm. after ten days. The initial dose was smaller than he used for treatment in influenzal broncho-pneumonia. Nevertheless, the result in the army showed that this vaccine gave some measure of protection. Leishman gave the following summary of results:—

	Number.	Incidence per 1000.	Pulmonary complications per 1000.	Deaths per 1000.
Inoculated ...	15,624	14.1	1.6	0.12
Not inoculated ...	43,520	47.3	13.3	2.25

It would be seen that the incidence of influenza among the non-inoculated in the army, 14.1 per 1000, was much less than the 50 to 300 per 1000 recorded in the American figures above, so that apparently a less severe type of disease was experienced in the particular army units concerned.

The vaccine now recommended and adopted by the Ministry of Health contains 400 mill. influenza bacilli per c.cm. instead of 60 mill. There is no explanation as to why this formula was adopted. It has met with much criticism, and the American experience, as well as that of those who have been using mixed prophylactic vaccines for years, seems to have been ignored.

It might be thought inadvisable, Dr. Wynn said, to inject persons suffering from chronic infections, but experience has shown that there is rarely any harm in injecting patients with chronic bronchitis, sinusitis, or arthritis. Pregnant women can safely be injected, and also infants, in spite of the advice from the Ministry of Health that the vaccine should not be given to children under 3 years of age. Children respond to vaccines very well, and he had no hesitation in giving suitably reduced doses to children under 3 years of age.

The second half of Dr. Wynn's paper was devoted to a consideration of vaccines in the treatment of a developed attack of influenza.

THE PROBLEM OF STILLBIRTH.

In the section devoted to the hygiene of maternity and child welfare Mr. BECKWITH WHITEHOUSE read a paper on the Medical Aspects of the Stillbirth Problem. The question, he said, was one of great national importance. The last report issued by the medical officer of health for Birmingham stated that during the year 1918 590 stillbirths occurred in the city—that is, 3.4 per cent. of all births. This figure did not include the large addition of babies who died within a few hours or days after birth from injuries and conditions directly dependent upon their entry into the world. What were the causes which underlay these facts? Were they sociological, depending upon such factors as housing, occupation, feeding, social status? Were they the result of constitutional disease in the parents or fetus, or, on the other hand, were they directly dependent upon various obstetric complications?

Sociological Factors.

The Public Health Department in Birmingham had commenced an investigation into the causes of stillbirth, 440 cases having been followed up in schedules issued by the medical officer of health.

From these it appeared that there was little difference between the number of stillbirths in the poorer and least healthy parts of the city and that in the residential and healthiest wards. The average of the poorest was 37, and that of the healthiest 38. Industrial work on the part of the mothers did not appear to react unfavourably on the incidence of stillbirths, for in 411 cases, 242 of the mothers were occupied at home and 169 were employed industrially. Of the latter 64 were at work for six months or more of the pregnancy, whilst 17 only were at work for less than three months. Legitimacy was not an important factor, since in 333 instances the baby was legitimate. In only 24 was it illegitimate. Housing and overcrowding appeared to have some influence, for the proportion of stillbirths occurring in houses with from three to six rooms was 39.5, against 34 in houses with from seven to eight rooms or over. These figures were a strong argument in favour of increased institutional accommodation for pregnant women.

Constitutional Factors.

Syphilis was still regarded as being a very potent factor in the production of intra-uterine foetal death. Mr. Whitehouse investigated collectively the obstetric histories of the women who had attended the venereal clinic at the General Hospital during the past year, and found that out of a total of 209 women 566 children had been born alive, whilst the stillbirths numbered 64, a proportion of 10 per cent. of the total. A fallacy was present in this gross number, since in many cases syphilis was contracted late in the obstetric life of the individual patient and cannot have had any influence

upon the previous pregnancies. Ninety-three cases of tertiary syphilis had been collected, and amongst these women 293 children were born alive and 51 stillborn, a percentage of 15. A very striking feature was revealed during the investigation—namely, the very high infant mortality attached to the children of syphilitic parents from causes not necessarily actually due to the disease itself, but pointing to lowered general vitality. Although the pregnancy terminated in the birth of a living and often premature but viable child, and therefore could not be labelled "stillbirth," the infant did not survive, and therefore fell into that large group of "potential stillbirth." Syphilis in the parents, if untreated, therefore, not only increased the risks of foetal intrauterine death, but to a marked degree diminished the chances of survival after birth. During the past year 25 women suffering from syphilis had been treated during their pregnancy at the General Hospital and admitted for their confinement. Amongst these patients no stillbirth occurred. By treating energetically throughout her pregnancy every expectant mother suffering from syphilis, either active or latent, it was possible greatly to diminish the risk of stillbirth from this cause.

Factors Concerning Fœtus and Delivery.

Mr. Whitehouse went on to deal with factors concerned with the foetus and method of delivery, referring to the figures of the Birmingham Maternity Hospital for the past ten years.

During the period 1910-1919 inclusive 5591 infants were born in this institution. Of these 4876 were born alive and 715 dead, a percentage of 12.7. Of the latter a cause of antenatal foetal death is assigned in 653 cases (91.4 per cent.) and unknown in 62 (8.6 per cent.). These results are expressed in Table I.

Live and Dead Births at Birmingham Maternity Hospital in Ten Years.

Total number of infants born	5591
Infants born alive	4876
Stillbirths	715 (14.6%)
Cause of stillbirth known	653 (91.4%)
Cause of stillbirth unknown— Macerated foetus, &c.	62 (8.6%)

Analysing the known causes of stillbirth in the 653 available cases it is possible to classify the material as shown in Table II.

Known Causes of Stillbirth.

Constitutional maternal diseases	18	Anomalies of umbilical cord	27
Prematurity	30	placenta	256
Toxæmia	94	Obstructed labour	192
Anomalies of foetus	36		653

The undue proportion existing between these individual items led to a more detailed analysis of the actual pathological conditions present.

Analysis of Pathological Conditions.

Constitutional maternal disease:			
Mitral disease	11		
Chorea	1		
Cancer of cervix uteri	1		
Ovarian cyst	1		
Exophthalmic goitre	1		18
Meningitis	1

Spina bifida	1		
Foetal heart disease	1		
Anomalies of umbilical cord:			
Prolapse of cord	25		
Cord round neck	1		27
Thrombosis of cord	1		
Anomalies of placenta:			
Placenta prævia	205		256
Antepartum hæmorrhage	51		
Obstructed labour:			
Obstructed labour (forceps)	85		
Craniotomy	50		192
Malpositions (version, &c.)	49		
Cæsarean section	8		

In considering the items set forth above three facts are at once evident: (a) The very high foetal death-rate from placenta prævia. (b) The danger to the child in obstructed labour, whether due to malposition or to disproportion between the foetal head and pelvis, and whether forceps or version are employed in such a contingency. (c) The great risk to the foetus in eclampsia.

Placenta prævia thus accounted for 31 per cent. of the total, a very high proportion, and this does not represent the total foetal mortality, for an addition is required in respect of the children born alive, but who subsequently die from injuries received at birth. Of the 317 cases of placenta prævia admitted to the hospital 212 babies were stillborn and 33 died in hospital, giving a gross foetal mortality of 77 per cent. The methods of delivery were as follow:—

Methods of Delivery in Placenta Prævia.

Method.	Cases.	Foetal death.	Percent-age.	Maternal death.	Percent-age.
Version	211	193	91·4	9	4·2
Natural	35	16	45·7	0	0·0
De Ribes's bag	15	11	73·3	3	20·0
Rupture of membranes	11	9	81·8	0	0·0
Forceps	9	9	100·0	2	22·0
Cæsarean section	5	2	40·0	3	60·0
Vaginal Cæsarean section	4	2	50·0	0	0·0
Induction	2	1	50·0	0	0·0
Extraction of breech	2	1	50·0	0	0·0
Vaginal pack	1	0	0·0	0	0·0
Hysterectomy	1	1	100·0	1	100·0

The favourite method of treatment for placenta prævia is version, with a foetal mortality in this complication of 91 per cent. and a maternal mortality of 4 per cent. The next method of election, if the case is so urgent that it cannot be left to nature, is the use of de Ribes's bag; here the foetal mortality is 73 per cent. and the maternal 20 per cent. Mr. Whitehouse is of opinion that improvement can be effected in the treatment of placenta prævia by the more general substitution of Cæsarean section for version and the other methods at present in use. During the 10 years it was performed 162 times at the hospital, with varying indications, pre-arranged and emergency, the total mortality from all causes being only 5·5 per cent.

Risk to the child from obstructed labour could only be diminished in numbers by careful clinical examination before labour actually commences. Here antenatal clinics might play an all-important part. If the medical profession, as a whole, was too occupied to expend the necessary time in investigating individual cases of pregnancy the State must accept the responsibility of providing more antenatal clinics, where such work could be carried out by routine. The reward would undoubtedly be an appreciable lowering of the stillbirth figures.

DOMESTIC ANIMALS IN THE SPREAD OF INFECTION.

At the Conference of medical officers of health Dr. W. G. SAVAGE, medical officer of health for the county of Somerset, dealt with three examples of alleged association between human and animal disease.

Bovine mastitis was a rather common condition, the chronic form being usually due to the tubercle bacillus, or less commonly to actinomycosis. The prevalence of cows with tuberculous udders was probably round about 1 per cent. The association of the acute variety with human disease had required a good deal of unravelling. Of 35 acute cases investigated by Dr. Savage for the Local Government Board in 1907-08, over 70 per cent. were due to streptococci, 16 per cent. to staphylococci, 1 to *B. coli*, and the rest of doubtful bacteriology. The *Streptococcus mastitidis* closely resembled the pathogenic streptococci of man, as found in cases of sore-throat, in morphological and cultural characters, but differed from them in pathogenicity, being of low virulence to animals. And yet extensive outbreaks of sore-throat and other septic conditions had been traced to milk infected from cows suffering from mastitis. He had described over 20 outbreaks of these diseases due to milk, in a good many of which the cause was traced back to cows suffering from this condition, one such outbreak, which was fully investigated, involving over 600 cases and definitely traced to an infective cow. The explanation of this apparent inconsistency was that the

cases in which a virulent type of organism occurred were examples of infection of the cow from a human source.

In 1911 and subsequent years outbreaks occurred in Boston, Chicago, Baltimore, and other cities which led to a differentiation of the human type of streptococcus in bovine mastitis by means of hæmolytic tests. The strains dangerous to man were always found to be hæmolytic, while the streptococcus of ordinary bovine mastitis was non-hæmolytic. Davis and Capps had shown that hæmolytic streptococci of human origin might cause mastitis lasting for several weeks in cows, the streptococci gaining access from an infection from the milker, whose hands were contaminated, perhaps, from a sore-throat. In an outbreak in Boston in 1917 (reported in January, 1920, by Brown and Orcutt) it was possible to identify the particular infective strain both from the mastitis fluid and from the sore-throats of the sufferers.

Outbreaks of Food-poisoning.

Food-poisoning outbreaks were all, or almost all, due to a secondary infection of sound food with members of the Gaertner group, the infecting agent being either *B. enteritidis*, *B. suisstifer*, or *B. aertrycke*. In a proportion of cases it was due to infection of the living animal with one of these bacilli.

In only a few of the recorded British outbreaks was there direct evidence of disease in the animals supplying the peccant food. In several cases where milk had been the vehicle the condition was traced back to infection of the cow with a member of the Gaertner group. The only two instances spread by meat from a diseased animal were those at Murrow and at Limerick. Continental outbreaks showed this association much more frequently.

Animals suffering from Gaertner group infection might recover from such conditions, but the bacilli persist, the animals acting as carriers, and undoubtedly a number of outbreaks had originated from the meat of sound animals being infected, by splashing and so forth, from the intestinal contents of such carrier cases.

In connexion with the secondary infection of food the importance of rats and mice must not be overlooked, since those animals frequently were infected with Gaertner group bacilli, and might act as a vehicle of infection.

Diphtheria and Cats.

That cats might be attacked with human diphtheria, or act as carriers of the bacilli, and so spread this disease, was a view very widely accepted amongst medical men and in the text-books. The author's investigations were along three lines. The examination of the throats of healthy cats and kittens quite unassociated with cases of human disease showed that in the swabs from the latter no organisms like diphtheria bacilli were detectable, but that from no less than five out of eight healthy cats bacilli were found growing on the cultivation media, which morphologically very closely resembled diphtheria bacilli, and which could not be distinguished from that organism in the films from the cultures. One cat re-examined three months later still showed these organisms. When they were isolated and their characters studied in pure culture it was manifest that they were not true diphtheria bacilli, nor were those tested pathogenic. All the cases mentioned above, where diphtheria bacilli were reported as found in the throats of cats associated with human disease, rested upon morphological appearances alone and never upon isolation and identification, and therefore were completely valueless in view of the above findings. A second line of inquiry was the examination of cats actually closely associated with human cases of diphtheria, and here, in several instances, as might be anticipated from the findings in healthy cats, bacilli morphologically indistinguishable from diphtheria bacilli were found in the cultures from the swabs. When isolated and fully investigated, however, none were found to be true diphtheria bacilli. The third line of investigation involved the experimental inoculation of kittens, to see if it was possible to infect them with diphtheria bacilli by natural channels. As many as 19 different experiments were carried out, and 10

different strains of human diphtheria bacilli were used, the virulence of four of them being fully tested.

"Massive and repeated feeding with highly virulent cultures (in one case on 11 occasions) were quite without effect. Kittens whose throats were inoculated by swabs with enormous numbers of diphtheria bacilli, either alone or mixed with staphylococci and streptococci grown direct from human cases of diphtheria, remained unaffected, and the bacilli had disappeared within 24 hours. The possibility that the failure to infect the kittens was due to the absence of a local nidus of growth was met by creating such a nidus by a preliminary scarification of the throat, and with other animals by painting with strong silver nitrate solution. Subsequent massive inoculation with diphtheria bacilli still failed to produce any infection or, what was remarkable, any persistence of the bacilli locally. The same striking fact was brought out by a series of nose-swabbings with heavy doses of diphtheria bacilli. In every instance the bacilli rapidly disappeared, and neither local nor constitutional symptoms resulted. These results were exceptionally uniform and concordant. It was found impossible either to infect the kittens or produce a carrier condition, even one of very short duration."

The whole series of experiments led Dr. Savage to the opinion that the common and widely accepted view that cats could suffer from a naturally acquired disease caused by the diphtheria bacillus was entirely without foundation. The reported cases of such an association were based upon insufficient examination and differentiation of the bacilli found, due to a failure to realise that a large proportion of healthy, normal cats contained in their throats bacilli closely resembling, and difficult to distinguish from, the true *B. diphtheria*.

TUBERCULOSIS.

Dispensary Treatment: the Ideal and the Real.

IN a report published as an appendix to the L.C.C. Report of the C.M.O. and S.M.O. for the year 1919 (P. S. King and Son, Ltd., price 5s.) there is an illuminating and admirably candid review of the work, and in some cases of the want of good work, at various tuberculosis dispensaries in London. The disclosures made certainly warrant revision of the conduct of a system on which the whole tuberculosis campaign hinges. One of the most valuable functions of the dispensary medical officer is visiting the patient in his home. Yet it appears that the tuberculosis officer attached to St. Thomas's Hospital is not allowed by the rules of the hospital to consult at the homes of patients. On this point the report is emphatic. "This is an unfortunate restriction, and it is desirable in the interests of efficiency that the rule should be revised." A fault of certain tuberculosis officers appears to be a lack of intensive study of the individual case. Cases in which the diagnosis is doubtful are kept dancing in attendance for perhaps a year; more and more are added to their number, till the machinery of the dispensary becomes clogged and there is no time for the physical examination of even a tithe of the patients. As the report puts it: "..... the observation cases cease to be observed, and the only thing that is done for them is that their medicine is repeated." The number of attendances made at these peccant dispensaries is accounted for mainly by the large number of children who receive treatment without diagnosis.

A far more efficient system was found to be adopted in other dispensaries, where great pains were taken to study each case intensively for a short period and to arrive quickly at a diagnosis. As for the actual treatment given at the various dispensaries, some seem to be perpetuating the pernicious "bottle-of-medicine" system. In one dispensary the drug bill amounted to more than £900, and the extent to which "drugging" still exists is illustrated by a hospital dispensary where 4569 prescriptions were dispensed for a total attendance of 4853. The medicine included 1785 bottles of cod-liver oil, alone or combined. In another case large quantities of virol were used. As the report points out, this wholesale "drugging" tends to make the patient rely more on the medicine and less on such essential matters as hygiene and diet. With regard to treatment by the

general practitioner, the attitude of the tuberculosis dispensary officer seems to have undergone a marked change. Formerly he wished to treat every tuberculous patient himself. At present many such officers realise that it is essential to maximum efficiency that the general practitioner should not be excluded from the treatment of this disease. It also appears to be admitted that the treatment of the individual case by the tuberculosis officer does not yield materially better results than when treatment is left to the general practitioner. Many other aspects of the dispensary problem are discussed in this report, which does not, mince matters, and which, instead of attempting to whitewash the backslidings of badly run dispensaries, goes so far as to name the worst managed districts and to indicate clearly the lines along which reforms should be made.

Insurance against Pulmonary Tuberculosis.

The Insurance Committee for Newcastle-on-Tyne has issued a survey of sanatorium benefit in the period July, 1912-December, 1919. The Committee's medical adviser, Dr. W. H. Dickinson, observes that in the majority of cases patients were not notified and relief was not sought till the disease was advanced. Thus, in 1918, 50 per cent. of the persons certified as dying of pulmonary tuberculosis had not been notified before death or had died within three months of notification. It was also ascertained that the average duration of illness before notification was 15 months. Dr. Dickinson makes some very pertinent suggestions in this connexion. In his opinion there should be some form of insurance against pulmonary tuberculosis, subsidies to consumptives being more urgently needed than pensions for persons over 65. As matters now stand, the expectation of life for pensioners of this age among the working classes is very much longer than for patients in whose sputum tubercle bacilli have been found. During the period under review only 66 per cent. of the insured persons known to have died from pulmonary tuberculosis in Newcastle applied to the Committee for treatment, and Dr. Dickinson is convinced that, were something more attractive than the ordinary "sickness benefit" available for these patients, an important step would have been taken towards securing the earlier diagnosis so essential to the patient and his family. Dr. Dickinson adds: "Obviously the consumptive who had been treated for months on end for 'bronchitis' would be far from satisfied when he learnt that he had been entitled to extra allowances, and had not received them. This dissatisfaction would soon bear fruit." With regard to the establishment of industrial colonies, as recommended by the Inter-Departmental Committee, Dr. Dickinson calculates that there are, roughly, 1200 cases of pulmonary tuberculosis living in Newcastle. Allowing for four contacts for each case, Newcastle alone would provide between 5000 and 6000 occupants for an industrial colony. Also, as about 200 new cases would for some years be arising annually, with 800 new contacts, the sum to be expended on the colony would be enormous.

Suggested Application of the Public Health Acts.

In the report of the Medical Adviser to the Belfast Insurance Committee for the year ending Dec. 31st, 1919, Dr. A. Trimble emphasises the relation to the incidence of tuberculosis of "real" wages, that is to say, the relation between wage and cost of living, as distinct from mere wage irrespective of the purchasing value of that wage. In a table showing the results of treatment it appears that 124 out of 1840 patients were cured or their disease became quiescent. In 738 cases there was a family history of tuberculosis, 113 patients having a father and 160 having a mother who had suffered from tuberculosis. The death-rate from pulmonary tuberculosis shows a fall from 2.7 per 1000 in 1918 to 2.1 in 1919. While the tuberculosis officer for Newcastle-on-Tyne advocates pensions for the tuberculous as a means towards stamping out the disease, the medical adviser to the Belfast committee advocates more drastic remedies. He writes: "What is urgently required is that not only should tuberculosis be placed on the list of infectious diseases, but the patient should be subject to all the provisions

of the Public Health Act, so that where a patient 'is without proper lodging or nursing accommodation,' and where the local authority is willing to provide for his institutional treatment, he should not be allowed to remain at home, a source of injury to himself and a menace to the health of those with whom he lives."

THE LEAGUE OF RED CROSS SOCIETIES: THE MEDICAL ADVISORY BOARD.

THE first meeting of the Medical Advisory Board of the League of Red Cross Societies was held at Geneva, at the headquarters of the League from July 5th to July 8th under the honorary presidency of Professor Emile Roux, director of the Pasteur Institute at Paris. Dr. Simon Flexner, director of the Rockefeller Medical Research Institute, served as chairman, and Colonel S. Lyle Cummins and Professor Giuseppe Bastianelli acted as secretaries.

The majority of the recommendations submitted to the Board by the Medical Section of the General Council of the League in March were approved. Those which will not be put into effect at this time were concerned chiefly with the establishment of laboratories and a museum, it having been decided that for the time being it would be wiser for the League to utilise existing facilities.

A Policy of Coöperation.

In general, the Medical Advisory Board outlined for the League a policy of coöperation with national Red Cross Societies and other health agencies, and of acting as a clearing-house for medical information. The latter function will continue to be accomplished through the League's publications and through the free medical information service of the Department of Medical Information. The publications include the *International Journal of Public Health*, a scientific organ; the *Bulletin of the League of Red Cross Societies*, a popular monthly, both published in four languages; and pamphlets of various kinds.

The support of national Red Cross Societies for the campaign against typhus and other communicable diseases in Poland was asked, and the coöperation of the League of Nations was requested.

The immediate organisation of a child welfare unit, and its despatch to some country which would engage gradually to take over its work and to duplicate its activities, was sanctioned. The work of this unit is to include the training of doctors and nurses, as well as the education of the public in child welfare. The Medical Advisory Board also suggested that the League of Red Cross Societies participate in creating or assisting in creating schools of puericulture or child welfare centres, and in providing scholarships for doctors and nurses in existing schools. A limited investigation into the causation of rickets in Vienna was recommended, if it seemed feasible.

Venereal Disease; Tuberculosis; Malaria.

Education in sex hygiene and antivenereal propaganda are to be continued by the Social Hygiene Department of the League, which also is to study the means by which it would be possible to reduce the cost of salvarsan; to promote regional conferences dealing with venereal disease; and to take measures to diffuse moral and physiological knowledge.

The antituberculosis measures to be undertaken by the League include the creation, in certain districts of several countries of Europe, of antituberculosis demonstrations. Each would carry out a preliminary survey of latent tuberculosis and open infection in the entire population of its chosen district according to age, sex, profession, and social groups; a statistical study of tuberculosis mortality and of the types and forms of the localisation of the disease; the establishment of an adequate number of dispensaries, run by specially trained physicians and visiting nurses; the organisation of open-air schools for children; and the education of the medical profession, as well as of the public, regarding the social fight against tuberculosis.

The proposed antimalaria programme of the League of Red Cross Societies in Spain was approved by the Medical Advisory Board, which also believed it suitable that the League study means of reducing the cost of quinine.

Sanitary Surveys.

The work outlined for the League's Department of Sanitation comprises the making of sanitary surveys, such as have already been carried out to a certain extent in Roumania and Slovakia; the promotion of public knowledge upon housing, pure water-supplies, and kindred sanitary subjects; a demonstration of the efficiency of chlorination in water purification; and the establishment of liaison officers in sanitation with the national Red Cross Societies.

National Red Cross Societies were advised to create, where possible, medical bureaux to maintain communication with the League of Red Cross Societies with regard to health. Adequate and full registration of vital statistics, international standardisation of forms and methods, and the stimulation of interest in statistical methods among physicians and the general public were urged. It was pointed out in this connexion that the major part of the collection and publication of statistics must remain under Government auspices, but that until international coöperation is fully established in this field the League of Red Cross Societies can do much effective work.

The Medical Advisory Board gave its approval of the work already carried out by the League of Red Cross Societies, and passed an especial resolution to this effect.

The different nations were represented on the Board as follows: Belgium, Dr. J. Bordet; Denmark, Dr. T. S. Madsen; France, Professor Emile Roux, Dr. Albert Calmette, Dr. Leon Bernard; Great Britain, Colonel S. Lyle Cummins, Sir Walter Fletcher, Sir George Newman; Italy, Professor Giuseppe Bastianelli, Professor Aldo Castellani; Japan, Professor Takasugi; United States, Dr. Simon Flexner.

Dr. William H. Welch and Dr. Hermann M. Biggs, of the American delegation, were unable to attend the conference, as was Dr. Carlos Chagas, of Brazil, the South American member of the Board. Professor Takasugi, while not a member of the Board, attended its sessions as a substitute for Professor Kinnosuke Miura, the Japanese representative.

VIENNA.

(FROM OUR OWN CORRESPONDENT.)

The Nationalisation of Drug Stores and Apothecary Shops.

THE Austrian Board of Health has laid before the National Assembly (our present House of Parliament) a Bill for nationalising all the existing apothecary shops and drug stores as well as pharmaceutical factories. The leading idea is that all such commercial enterprises should become property of the State, although they need not be run by the State. The present owner may rent, or duly qualified government officials may conduct the business. All the existing State apothecary stores—in public or military hospitals—will be opened for public use. No new licence will be issued to private individuals; the old ones will be gradually cancelled. If an apothecary intends to dispose of his store he must offer it first to the State, and only if his offer is refused may he put it up for sale to private persons. The 20-fold average profit of the last seven years is the basis of the transaction. Besides this sum, the quantity of drugs, the stock, and outfit must be paid for by the State. If the possessor dies the same procedure holds good for the benefit of his family or heirs. The establishment of new drug stores in a certain place can be demanded by the municipality or the legal representatives of the medical profession, the apothecaries, or the "sick clubs" (Krankenkassen), and can be effected only by the State. The rentability of the existing drug stores in the neighbourhood must not be endangered by the new licence.

Every doctor of medicine in active practice is entitled to dispense such remedies as are required for urgent or immediate use or application, but he must buy them in a public drug store. Naturally this Bill, the leading lines of which have just now been sketched, meets serious resistance from the owners of dispensaries and pharmaceutical shops. Their chief argument is that by this Bill prices will be raised, although the chief reason for its introduction was the universal feeling of the population that they were overcharged by the dispensaries. On the other hand, all the persons who have taken up the study of pharmacy with a legitimate prospect of obtaining in due time a licence, and thus find a comfortable living, are naturally disappointed. Nevertheless, it is likely that the objections will be overcome and that the public will derive benefit from this procedure. The State will also gain by the new system.

Definite Settlement of Relations between Dental Surgeons and Dentists.

The present regulations pertaining to the work of technical dentists and dental surgeons were of such an unsatisfactory nature that they were a source of frequent annoyance and dispute between the patients, the profession, and the dentists of both kinds. Whilst the dental surgeons—they must be fully qualified medical men, with a normal medical training and graduation in this country—claim that they are entitled to do all kinds of work necessary for the treatment or repair of the teeth and the insertion of plates or artificial teeth in the mouth of a patient, the technical dentists demand that the doctors should limit their work to the purely medical or surgical part of treatment (filling of teeth, extraction, treatment of diseased roots). All the rest, including the manufacturing of artificial plates and teeth, the adaptation of such, the insertion of teeth into existing sockets, as well as all preparatory work necessary in that process, should be their own domain. But as such strict limitations are scarcely possible in actual practice—both kinds of work must needs overlap—there was always trouble. The technicians form a special guild, a corporation, of which doctors could not become members, and this corporation not only wanted to exclude doctors from all technical dental work, but demanded for themselves the right to perform in the mouth of patients all work necessary to make their apparatus fit and good for use. At last Government has worked out, with the co-operation of doctors and technical dentists, a Bill which will do away with all differences of opinion. The chief point is, that the existence of an independent corporation of technical dentists will cease. In future, the technician will be only a "hand" in the office of the dental surgeon. But the technicians now practising will be permitted to do certain minor pseudo-surgical work in the mouth with the exclusion of all bloody operations (especially the extraction of teeth may not be performed by them). No new licence will be granted to a technical dentist, and all these men practising at present will be controlled by the Board of Health. Only doctors of medicine will in future be permitted to treat diseased teeth and will be entitled to employ qualified technical dentists; these latter will be regarded as sanitary assistants. These men, and persons desiring to learn technical dentistry, will be able to do so in special schools attached to dental departments of public hospitals, or they will be able to "apprentice" with a duly qualified dental surgeon. By these means the technicians who until to-day have been in bona-fide practice will be able to continue their practice, whilst in about 20-30 years only doctors will treat diseases of teeth and mouth.

Post-graduate Lectures during the Summer Months.

A series of post-graduate lectures will be delivered during the months of August and September by a number of clinical assistants and privat-docents of the University of Vienna, the course including 6 to 24 lectures, open to graduates of all countries. Also special courses and classes will be arranged, lasting seven weeks respectively. The whole range of medical and surgical knowledge comes into review. Laryngology, otology, dermatology-syphilis, ophthalmology, pediatrics, and

pathology will be chiefly dealt with. It may interest English readers to learn that American doctors are already coming to Vienna. At present several are working here in the clinics, and for the winter term, commencing in October, a considerable number have already booked places. Order and regular running of the hospitals and clinics has been ensured by this time, so that visitors may expect to find their time well spent.

Marked Decrease of Population Owing to the War.

The report of the census of the population taken on Dec. 31st, 1919, has recently been published and shows clearly the deleterious effects of the war. Austria has been cut down to a population of 6,182,450, whilst in the same area there lived before the outbreak of the war (1913) 6,575,000 persons. If the average increase had not been interfered with the population would have been about 6,872,000. The actual drop is about 700,000, due in some part to a very marked emigration. Many persons preferred to go to the new formed national states, partly for family reasons, partly from a business standpoint. The centres of depopulation are the large cities and towns. Vienna counts only 1,880,000 inhabitants, or 200,000 less than in 1913; the rural districts are not much worse off than before the war. But still even there the decrease is noticeable. A marked change has taken place in the relative numbers of the sexes. The actual war loss of male lives in the Austrian area amounts to a little more than 180,000, apart from the deaths due to malnutrition. The percentage of men and women bears at present the relationship 47 to 53, against 49.5 to 50.5 in pre-war time. The number of children is by 20 per cent. less than before; the birth proportion of sexes is now 109 girls to 100 boys. A sad outlook for the regeneration of the race!

Vienna, July 26th.

CERTIFICATION OF INSURED PERSONS
IN IRELAND.

THE Irish Insurance Commission has issued an important letter to each medical certifier in Ireland. In the first place the announcement is made that the Treasury has agreed to raise the remuneration for certification by 40 per cent. This increase is given as the result of a demand made on behalf of the profession by the Irish Medical Committee, which refused as inadequate a previous offer of 25 per cent. rise. The increase now given is roughly proportional to that recently granted to panel doctors in Great Britain, and inadequate as it is when the rise of prices is considered the Irish Medical Committee had no choice but to accept it. The increased remuneration is to date from Jan. 1st, 1920.

The Commission in its letter goes on to state that certain other matters in regard to certification came up for discussion between the Commission and the representatives of the Irish Medical Committee. The Commission complains of certain irregularities in certification at the hands of certain certifiers, and also with some emphasis of the laxness of local medical committees in investigating the complaints submitted to them. It appears that some certifiers have been in the habit of issuing certificates in mass, either retrospectively or prospectively, and the Commission points out how such an irregularity should be avoided. More serious attention is drawn to the issue of certificates without previous medical examination, an act which, even if no fraud be committed, is without excuse. Certain minor duties in regard to the notification of tuberculosis and other matters undertaken by certifiers appear to have been largely neglected.

It is understood that a new and more definite procedure in regard to the investigation of complaints has been agreed on. Much of the delay in the past has been due to the difficulty of assembling the Local Medical Committee in country areas. In future the duty of investigating complaints is to be delegated to a "complaints subcommittee" of three or five members, being in convenient proximity to a suitable meeting place. All the relevant facts, as far as known to the Commission, are to be submitted to the members of the committee in advance of their meeting. Both the accused certifier and a representative of the Approved Society bringing the charge is to have the right of being present at the meeting of the subcommittee, though the members come to their decision in private. Our Dublin correspondent, to whom we are indebted for these particulars, regards the procedure now outlined as fair and reasonable, and expresses a hope that the Local Medical Committees will take this part of their task seriously. It should, he adds, be remembered that the reference of complaints to the local committee is designed to protect the interests of medical men.

Correspondence.

"Audi alteram partem."

HELMINTHIC INFECTIONS AND PELLAGRA.

To the Editor of THE LANCET.

SIR,—May I be allowed a few words of comment upon the last paragraph of Lieutenant-Colonel P. S. Lelean's letter published in your issue of July 17th? Colonel Lelean writes that if the deficiency factor is only a contributory factor to a determining cause yet to find, the suggestion that the latter is to be sought in a helminthic infection (such as with *Ascaris*) is equally difficult of acceptance. Now, so far as regards the suggestion made recently by myself in this connexion, I have not considered the helminthic infection as the determining cause and the deficiency factor as only a contributory one. The matter is rather the other way round.

As will be clear, I think, to readers, both of my section of the Pellagra Report on the Turkish Prisoners of War, and of my letter published in your issue of May 28th, the question is whether a helminthic infection is to be regarded as an essential contributory factor, perhaps especially important as a predisposing cause; a dietetic deficiency being considered (in most cases, at all events) as the actual determining cause. As I wrote:—

"There is, of course, no intention of suggesting here that helminthic infections, by themselves alone, constitute the specific cause of pellagra: such infections are known to be prevalent in many districts and countries where pellagra never, or only rarely, occurs."

May I illustrate by a rough analogy? Chronic, local irritation or stimulation is known to be often a most important contributory or predisposing cause of malignant disease; but this alone is not regarded as the immediate determining cause of malignancy, because a malignant growth does not necessarily supervene upon such a condition.

In the case of pellagra what I had in mind was that, as regards the extent of their responsibility, the two factors might perhaps stand in relation to one another in this way. The greater the adverse effect of helminthic intoxication (and this may not be the same thing as the heavier the infection itself), the less would be the degree of dietetic deficiency which would suffice to produce suprarenal inadequacy and pellagra, and vice versa. With reference to the Turkish prisoners, I stated in the summary of my report that the occurrence of *Ascaris* eggs was very general, not only amongst the pellagrins but equally amongst those who were liable at any time to become pellagrous. Just at the time I was at Kantara, the incidence of pellagra was becoming very high; and had not the labour been knocked off, one would hesitate to say how many of the "apparently healthy" Turks would not have gone on to show a manifestly pellagrous condition. I do not think, therefore, that my suggestion is so difficult of acceptance.

Is it known whether any of the prisoners of our M.E.F. and E.E.F. in Turkish hands showed symptoms of pellagra? And, if so, whether the cases occurred among the British or the Indians, or both? Because certainly the Indians would be more generally infected with helminths than the British. At any rate, as a first step I think it would be worth while for workers in pellagrous areas to endeavour to ascertain whether there is a distinct correlation between cases of pellagra and the occurrence of helminthic infections.

I am, Sir, yours faithfully,

July 31st, 1920.

H. M. WOODCOCK.

THE TUBED PEDICLE IN PLASTIC SURGERY.

To the Editor of THE LANCET.

SIR,—The operating books, surgical records, and ward sisters' report books of the Queen's Hospital show the following statement of fact. The first occasion on which the pedicles of a face flap were definitely tubed occurred

at the first operation I performed on A.B. V., the burnt seaman, the operation taking place on Oct. 3rd, 1917. These tubed pedicles progressed so well that the second stage operation, division of pedicle towards its base for use on the face, was performed on Oct. 17th, 1917 (Mr. H. C. Mallison for me). Captain J. L. Aymard's case, B. C. H., was operated on Oct. 18th, 1917, when he designed an original flap for making the nose and at the same time "tubed" it, in the same way as was my case. I am to blame in not informing Captain Aymard at the time he published his rhinoplasty case in your paper that he was not the first to get on to the principle of "tubing" the pedicle.

I am, Sir, yours faithfully,

H. D. GILLIES.

Queen's Hospital, Sidcup, August 3rd, 1920.

THE CLINICAL DIAGNOSIS OF DIPHTHERIA.

To the Editor of THE LANCET.

SIR,—I have followed with great interest the recent correspondence on the above subject. Being able to lay claim to considerable practical experience of both sides of the problem—the clinical and the bacteriological—I make bold to set forth some views on the subject. If it were always remembered that there can be no such thing as infallibility, clinical or bacteriological, there would be no occasion for "exclusive advocacy" by the holders of opposing views. In this matter of diphtheria diagnosis there is no time for opposition and argument. There is urgent need for coöperation and agreement. The clinical manifestations of diphtheria cannot be systematised with absolute certainty. However sure each of us may have been of his ability to dogmatise upon faucial lesions, sooner or later admission had to be made of a mistaken diagnosis. I think such must represent the experience of all fever workers. How could it be otherwise? So equally must bacteriological dogmatism be impossible where diphtheroid organisms are in question. Many times the clinician must be disagreeably surprised by the variety of bacteriologists' opinions where *B. diphtheria*, *B. hofmanni*, and diphtheroids are under judgment.

Some such considerations may have been in Osler's¹ mind when he remarked that—

"The clinical and bacteriological conceptions of diphtheria are at present not in full accord. On the one hand, there are cases of simple sore-throat which the bacteriologists, finding the Klebs-Löffler bacillus, call true diphtheria. On the other hand, cases of membranous, sloughing angina, diagnosed by the physician as diphtheroid, are called by the bacteriologists pseudo-diphtheria or diphtheroid angina. The term diphtheroid may be used for the present to designate those forms in which the Klebs-Löffler bacillus is not present. Though usually milder, severe constitutional disturbance and even paralysis may follow these so-called pseudo-diphtheritic processes."

Surely the foregoing is a laboured attempt to make distinction where there is no difference. It frequently happens that a patient suffering from local and general symptoms and having all the clinical characters of diphtheria, cultures "negative" for as many days as are required to rid the throat of the false membrane. Is it to be wondered that "clinical and bacteriological conceptions of diphtheria are not in full accord"? The explanation of the apparent inconsistency is simple. A consideration of the histological structure of the false membrane will demonstrate the mechanical impossibility in given cases of a swab, lightly rubbed upon the surface, reaching the underlying diphtheria bacilli. The parts touched are swarming with pyogenic cocci, which, on culture by the bacteriologist, must give a "negative field." The cold scientific fact is that the particular swab submitted for examination is "negative." The cool conclusion that the patient involved has no diphtheria organisms in or about the fauces, hence cannot be suffering from diphtheria, is unscientific, and only serves to create a situation of professional embarrassment.

Scientific procedures cannot altogether supersede clinical observations. They must serve as valuable aids, and, if accorded that function, but not relied on

¹ The Principles and Practice of Medicine, pp. 192-193.

and acted upon slavishly, there will be no need to state such an apparent contradiction in terms as that—"though usually milder, severe constitutional disturbance, and even paralysis, may follow these so-called pseudo-diphtheritic processes." With the realisation that there need be no incompatibility between the bacteriologist's "negative" finding in an isolated throat swab and the practically undeniable presence of a clinical diphtheria, scientific judgment need no longer be questioned nor clinical prescience discredited.

To sum up, it may be said that some cases of diphtheria, probably the most severe, can only be diagnosed clinically, whilst others, certainly the mildest, can alone be proved by the bacteriologist. Apart from these extremes, the vast majority can be correctly and expeditiously diagnosed by correlating the clinical appearances with the bacteriological findings.

I am, Sir, yours faithfully,

JAMES LAW BROWNLIE.

Glasgow Corporation Laboratory, July 29th, 1920.

VENEREAL PREVENTION.

To the Editor of THE LANCET.

SIR,—With reference to the report published in THE LANCET of July 10th of the speech by the Minister of Health to the deputation received by him on July 2nd from the Society for the Prevention of Venereal Disease, we ask you to insert the following remarks.

Dr. Addison's reply was far short of convincing the deputation. He expressed his strong opinion that the Society's proposal would stir up intense and vehement opposition, and urged further his view that there was no basis of ascertained fact on which it was quite safe to dogmatise. The Society, on the other hand, holds that there is abundant evidence available regarding the successful use of medical prevention, on which positive teaching can be securely and justifiably based. It thinks, further, that the Minister's fear of agitation was exaggerated, and that public opinion is setting in the direction of the views it is advocating.

But a more important point for comment is the error made by the Minister when, in elaborating his main argument against applying the Society's preventive procedure to the civil population, he said that "they could not deal with a population of 40 millions on the same basis as Sir Archdall Reid, with iron discipline at his command, could deal with 2000 soldiers at one time." The information about Dr. Reid's experiences supplied to Dr. Addison was seriously wrong. These experiences were spread over nearly three years, among a fluctuating population of soldiers in barracks amounting to about 40,000 in all. He lectured to all the men arriving at barracks, in smaller or larger groups, sometimes even to one man at a time. Then he informed them that those who chose to run risks and wished to protect themselves could obtain the necessary disinfectants by application to the orderly, and he told the men how to use them. There was no "iron discipline"; in fact, no discipline at all. The men were warned and instructed in the same way that the Society thinks applicable to the civil population. There is certainly no necessity for either soldiers, sailors, or ordinary civilians to be "scientific" in order to carry out clear instructions based on scientific knowledge.

Lastly, we would note that the findings of the Inter-Departmental Committee, which Dr. Addison referred to as "a strong body of men whose advice he asked," have been already definitely challenged more than once, and that that Committee's report has been deemed by many competent critics to bear the mark of an insufficient inquiry and a foregone conclusion.

We are, Sir, yours faithfully,

H. BRYAN DONKIN,
JAMES CRICHTON-BROWNE,
W. ARBUTHNOT LANE,
G. ARCHDALL REID.

London, August 4th, 1920

DRUGS AND THEIR ACTIVE PRINCIPLES.

To the Editor of THE LANCET.

SIR,—The leading article in THE LANCET of July 24th dealing with the subject of galenicals *versus* active chemically separated constituents, raises a most important pharmacological point—the pharmacology of the parent substance in many cases cannot be entirely identical with that of the isolated principle. To give a homely illustration, can it be admitted for a moment that a few grains of caffeine in hot water represent the same thing as a cup of tea?

When, as was shown in a series of researches published some years ago from your Laboratory that in a tea infusion the alkaloid was in definite combination with tannin as a compound breaking up slowly in the organism, it seemed to me clear that tea must be a different thing pharmacologically from caffeine or its salts. The question appears to me to hang on the colloidal state. Galenicals all through are colloids, slowly diffusible; active constituents are crystalloids, rapidly diffusible. Examples of both are obvious. Morphia and its salts surely cannot be put precisely on the same pharmacological basis as opium.

I am, Sir, yours faithfully,

GALEN.

August 3rd, 1920.

Parliamentary Intelligence.

HOUSE OF LORDS.

TUESDAY, JULY 27TH.

Health Resorts and Watering-places Bill.

LORD SOUTHWARK moved the second reading of the Health Resorts and Watering-places Bill, which had passed the Commons. The Bill proposed to enable local authorities to levy a 1d. rate for advertising health resorts and watering-places. This power was given to Irish local authorities in 1909.—LORD ASKWITH moved the rejection of the Bill on the ground that it was unnecessary and uneconomical.—After some discussion, in which several noble lords opposed the Bill, Viscount ASTOR (Parliamentary Secretary to the Ministry of Health) said that the Government did not officially adopt the measure, but in the Commons left it to the free vote of the House, and they proposed to follow the same course in their lordships' House.—On a division the Bill was rejected by 38 votes to 12.

THURSDAY, JULY 29TH.

Proprietary Medicines Bill.

VISCOUNT ASTOR, in moving the second reading of the Proprietary Medicines Bill, said that it was introduced in fulfilment of an undertaking given by the Lord Chancellor on behalf of the Government last year. It had been framed on the recommendations of the Select Committee which reported in 1914. The Committee's recommendations were in the nature of a compromise, and were not based on either of the two conflicting views. This country was very much behind several of our dominions, as well as most other civilised countries, in its treatment of proprietary and patent medicines and surgical appliances. As an example of the way in which our public were victimised the Select Committee quoted the instance of a man who came with a certain instrument to this country and was reported to have made over £60,000 by its sale. He went to France and was sentenced to three years' imprisonment, as well as heavily fined, for trying to sell the same instrument. Additional legislation was certainly necessary here to deal with the matter. At the present moment there was no Minister or Government department which was responsible for protecting the public, or for seeing that the public did not suffer grievous injury. The Bill did not propose to protect the purse of the public, though possibly amendments might be moved later to strengthen the Bill in that respect. Injury might be caused in one or two ways. Sufferers who purchased and attempted to use these appliances and medicines very often postponed going to a proper medical practitioner while trying to treat themselves. The delay very often aggravated their ailment, sometimes very seriously. In other cases actual injury was caused through these remedies. They proposed to prohibit the advertisement and sale of remedies purporting to treat, cure, alleviate, or prevent diseases which were set out in the schedule—cancer, consumption, diabetes, certain diseases peculiar to women, fits, epilepsy, deafness—because they knew that serious risk was involved if sufferers tried to treat themselves by using a patent drug. These were serious complaints, and it was not in the public interest that people, haunted by fear, should

be encouraged to use these remedies. Too often they merely touched a symptom of the disease. A case was quoted in the report where a particular medical wine was advertised, and it was stated that if two wine glasses full were taken that was a sufficient amount to cause sleep. It was recommended for children in these words, "For colds, coughs and bronchial affections." It contained cocaine, or the elements of cocaine, and nobody would advocate the continuation of a law which allowed or encouraged people to purchase cocaine in order to make their children sleep when they were suffering from a cough. It was essential that they should take powers to deal with these evils. In a limited number of cases death was caused, particularly where remedies were used intended to produce abortion. A considerable number of remedies were advertised as being suitable for female irregularities. He was told that at the best these remedies were useless, and that too often the most serious consequences resulted from their use. It was impossible, he was told, to kill an unborn child without endangering the life of the mother. Some of these remedies were intended to give lead poisoning. It was quite true that you might kill the unborn child by this means, but too often they also killed the mother. These remedies also led to blackmail. A case was quoted of two men who had threatened to expose the purchasers of a particular remedy intended to cause abortion. The police intercepted 600 letters containing two guineas each from these unfortunate women, who were paying this money under a threat of exposure. If the Bill did nothing else but prevent this reprehensible practice they would be justified in trying to pass it. The Assistant Director of Public Prosecutions said it was almost impossible to prove fraud, and that practically the law was non-existent. They could not expect the purchaser of a remedy intended to produce miscarriage to come forward after having bought the remedy and say: "I bought this remedy in order that I should be able to commit a crime. I have not been able to produce miscarriage. I have been defrauded." He knew a case where a bottle of mixture was sent with the intimation that the powerful and certain action of the medicine contained in the bottle necessitated the warning that the contents should not be taken by those expecting to be mothers, as the medicine was very liable to cause a miscarriage. That was the way in which these drugs were brought to the notice of a large number of unfortunate women who too often in the past had availed themselves of them. He would quote a brief paragraph from the Report of the Select Committee which summarised, very briefly, the situation. The Committee stated:

"For all practical purposes British law is powerless to prevent any person from procuring any drug, or making any mixture, whether potent or without any therapeutical activity whatever (so long as it does not contain a scheduled poison), advertising it in any decent terms as a cure for any disease or ailment, recommending it by bogus testimonials and the invented opinions and facsimile signatures of fictitious physicians, and selling it under any name he chooses on the payment of a small stamp duty, for any price he can persuade a credulous public to pay."

The Bill proposed that a register should be made on which every proprietary medicine and surgical appliance and the owners thereof should be registered. The sale of unregistered remedies was prohibited. Powers were taken, subject to the right of appeal, to remove the owner of a proprietary medicine from the register if his remedy was considered too dangerous to health. Powers were also taken to compel the owner to disclose the contents, the formula, the ingredients to the Government privately and in confidence. Heavy penalties would be imposed for non-disclosure. Further, they prohibited the advertising of remedies purporting to prevent, cure, or relieve the diseases which were set out in the Schedule. Clause 5 stated that the alcoholic contents of a patent medicine must be given on the label. Many of the medicated wines contained as much alcohol as some of the heaviest wines and twice as much as claret. A particular medicine referred to by the Committee which was recommended for use at the time of confinement was found on analysis to contain something like 60 per cent. of alcohol and the rest was apparently pure water. This was recommended as assisting confinement and producing fine and healthy babies. The Bill prohibited correspondence with the vendors, and the enclosure of literature with one remedy recommending the use of another remedy. They also prohibited the advertising of remedies suggesting that they were useful or could be used for procuring abortion. Clause 5 set out that all regulations must be laid before Parliament. The Minister of Health was made responsible for the supervision of the matters dealt with. In Clause 10 there was a definition of a "proprietary medicine." They excluded from the definition those proprietary medicines which were not advertised, pushed, or puffed in writing as being remedies, or having special therapeutic qualities. They proposed to exclude mixtures the composition of which was known, which were made by well-known and reputable chemists, and which were not pushed for sale on the ground that they had special

therapeutic qualities. Nor did the definition include any recognised drug or preparation for which no monopoly was claimed. He knew that the press derived a large revenue from the advertising of patent medicines and surgical appliances, but he had too high an opinion of the press as a whole to believe that they would attempt to stop the passage of the Bill.

Lord ASKWITH said that the noble Viscount had not quite brought before their lordships the importance of this industry as a whole, which might be judged from the fact that last year more than £1,250,000 was paid in stamp duty to the Inland Revenue. He understood that there were about 10,000 retail pharmacists in the kingdom, apart from the bigger shops, with an enormous number of formulæ for making these proprietary medicines. The industry employed a very large number of people and produced a lot of articles, many of which were extremely useful to the community at large; and though everyone deprecated the remedies mentioned by the noble Viscount, yet there were other remedies which almost every man, woman, and child in the country used on and off in the course of the year. He was sure that there could not be anyone in their lordships' House who had not at times derived great advantage from taking a proprietary pill. He agreed that regulation was necessary, but a good opportunity should be afforded to those concerned to see that the Bill did not affect them unfairly.—Earl RUSSELL said if it was their object to see that the public were not defrauded the best thing was to state in the plainest language on the wrapper the contents of the medicine, and he would put down an amendment to that effect for the Committee stage. He thought that instead of the registered ingredients being kept secret they should be furnished to Parliament in a White Paper, so that they might be available to the press, or anyone who wished to see them. He doubted whether there was any such thing as a real secret in the composition of these medicines which was not known to the Pharmacopœia. He thought that it would be just as well if venereal diseases were included in the Schedule of the Bill.—Lord EMMOTT said he fancied that this Bill would probably need another very considerable bureaucracy. On the face of it it seemed to him rather un-English to demand a full disclosure of ingredients unless a very strong case could be made out for doing so. He hoped that the Bill would not be pushed in this period of the Session.—Viscount KNUTSFORD, while hoping that there would be no delay in passing the Bill, said he thought a man who invented a machine to help one to hear, or a good truss, ought to be allowed to advertise it.—After further discussion Viscount ASTOR replied briefly to the points raised, and the Bill was read a second time.

HOUSE OF COMMONS.

WEDNESDAY, JULY 28TH.

Medical Attendance for Soldiers on Demobilisation Furlough.

Captain COOTE asked the Secretary for War whether he was aware that if soldiers on demobilisation furlough fell so seriously ill that they were unable to move they were unable to report at the nearest military hospital, and therefore had to bear the whole of the expense of medical attendance until such time as they could be moved into hospital; whether he was aware that such men were not upon any panel and could not therefore secure free medical attendance from civilian practitioners; and whether in such cases he could cause a refund to be paid on account of medical expenses incurred.—Sir A. WILLIAMSON (Financial Secretary to the War Office) replied: Soldiers on demobilisation furlough are entitled to free military treatment from a military source. If the seriousness of the soldier's condition makes it impossible for him to report personally it would generally be practicable for a relative or friend to send the necessary intimation to the military authorities. If this were done the cost of private treatment incurred up to the time of removal to a military hospital would be refunded. If the soldier were too ill even to arrange for his illness to be reported, and his relatives were unaware of the correct procedure, a refund of the medical expenses would not be refused on that account.

New Dental Legislation.

Mr. RAFFAN asked the Minister of Health whether he could now state when it was proposed to introduce legislation for the purpose of carrying out the recommendations of the Departmental Committee on the Dentists Act, 1978.—Dr. ADDISON replied: The Bill will be introduced before the recess.—Mr. RAFFAN: Is the right honourable gentleman aware that the introduction of legislation on this subject was promised before the Whitsuntide recess, and can he say definitely if it will be introduced before the recess?—Dr. ADDISON: I expect it will.

Destruction by Rats.

Mr. GRUNDY asked the Parliamentary Secretary to the Ministry of Agriculture whether he was aware that rats were now consuming not only the actual sum of the bread

subsidy, which amounted to £45,000,000, but at the present price of grain nearly twice that amount; and whether he could state what action his department was taking to rid the country of these rodents.—Sir A. BOSCAWEN replied: I am aware that the depredations of rats are responsible for the loss of very considerable quantities of food, including grain. Any estimate of damage must necessarily be problematical, and I cannot vouch for the figure mentioned by the honourable Member. Since my department assumed responsibility for supervising the measures for the destruction of rats every effort has been made to instruct local authorities as to their duties under the Rats and Mice (Destruction) Act, and by personal instruction of their officers and the issue of pamphlets and notices to the press to call attention to the waste of food and damage to property caused by rats. As a result there has been a considerable reduction in the number of rats in certain parts of the country where effective measures have been taken, and it is to be hoped that such counties which have not as yet taken steps to organise schemes of rat destruction will shortly do so in view of the undoubted benefit and saving to the community of such action.

Suggested Railway Concessions for Disabled Service Men.

Captain BOWYER asked the Minister of Transport whether he was aware that many disabled ex-soldiers in this country were put to discomfort, and in many cases suffering, through having to travel in overcrowded carriages where it was impossible for them adequately to protect artificial limbs and stiff joints, and other effects of serious wounds, from jars and blows inevitable in view of the overcrowded state of the carriages; whether he was aware that in Belgium a reduction of 75 per cent. on all fares was granted to ex-Service men; and whether he would consider the possibility of adopting similar measures in this country, the effect of which would be to enable seriously wounded men to travel by better-class and therefore less crowded carriages.—Mr. NEAL (Parliamentary Secretary to the Ministry of Transport) replied: I was not aware of the fact mentioned by my honourable and gallant friend. The cost of any concessions in railway travelling must ultimately fall on other users. I do not think the method suggested is the most suitable way of dealing with the class of case mentioned, but I shall be glad to discuss the whole question with the honourable Member.

Condemned Food.

Major BARNES asked the Food Controller if his attention had been drawn to statements that, owing to the vigilance of the local inspector of food, there was recently discovered 60 tons of meat unfit for human consumption released from the stocks belonging to the Government for the food of the population of Newcastle-on-Tyne; whether the total amount of such food so detected during the past 12 months approximated to 800 tons; and if he would see that meat of a quality fit for human food was sent to that city.—Sir W. MITCHELL-THOMSON (Parliamentary Secretary to the Ministry of Food) replied: I am unable to state the total amount of food condemned at Newcastle during the past 12 months, but the total quantity since the beginning of this year is 164 tons, which includes a considerable quantity of home-grown beef condemned for tuberculosis. In at least two cases (representing approximately 30 tons of imported meat) the meat had been sold elsewhere by the Ministry and had been despatched by the buyer from the place of sale to Newcastle. The remainder of the cases are being investigated. All meat which is released by the Ministry for sale comes under the jurisdiction and the inspection of local inspectors in the same way as if it were privately owned, and there is no ground for the suggestion that the agents of the Ministry have attempted to issue for human consumption meat which was unfit for that purpose.

Slaughter Houses and Public Health.

Mr. DONALD asked the Minister of Health if he would state whether Ireland was represented on the Committee to consider and report on the legislative and administrative measures necessary to secure adequate protection for the health of the people in connexion with the slaughtering of animals for food; and whether Ireland would be included in the Committee's Report.—Dr. ADDISON replied: The answer to the first part of the question is in the negative. The terms of the Committee's reference limit its consideration to the problem as it affects England and Wales.

THURSDAY, JULY 29TH.

Causes of Death of Service Pensioners.

Mr. TYSON-WILSON asked the Minister of Pensions if he could give, approximately, the cause of death of the officers and men who had died since pensions were granted them.—Mr. MACPHERSON replied: I regret that in view of the regrettably numerous cases involved the information desired could not be furnished except with a very great deal of research and labour, which I cannot ask my staff to undertake.

The Dissatisfaction with the Pensions Appeal Tribunal.

Mr. CHARLES EDWARDS asked the Minister of Pensions if he would consider the appointment of a Committee to amend the Appeal Tribunal with a view to giving the greatest possible satisfaction to discharged disabled men.—Mr. MACPHERSON: I have pointed out that the Ministry of Pensions have no power whatever over the Pensions Appeal Tribunal. It is a body appointed by the Lord Chancellor. It was enacted because the House was not satisfied that the Ministry of Pensions would bring to bear on any particular case a fair mind. The House, having insisted on this tribunal being appointed, I am astonished to find any honourable Member coming to any other conclusion than that the Pensions Appeal Tribunal, which is an outside body, is the best possible one to consider these cases.—Sir E. CARSON: Is not this rule as to whether a particular complaint was contracted or caused by service in the war one that ought to be very liberally construed, having regard to the difficulties of saying when a disease commenced?—Mr. MACPHERSON: I quite agree. It is the case, and it is most difficult. As a matter of fact, appeal to this Pensions Appeal Tribunal has been granted in 70 per cent. of the cases.

Captain COOTE asked the Minister of Pensions whether, if a man was refused pension in the first instance on the ground of non-attributability and was subsequently granted a pension by an appeal board upon a decision that his disability was attributable to war service, the man was entitled to arrears of pension at the rate granted by the appeal board as from the date of his first application for a pension or only as from the date of his appeal board.—Mr. MACPHERSON replied: My honourable and gallant friend is under some misapprehension as to the powers of the Pensions Appeal Tribunals, to which I presume he refers. These tribunals do not assess the rate of pension, but only decide the question of attributability or the contrary. Where the tribunal finds in favour of an appellant arrears of pension are granted at the rate appropriate to the degree of disablement found by my medical advisers to have existed from time to time for a period not exceeding one year prior to the date on which the appeal was made.—Captain COOTE: Is there any reason why a pension should not be granted from the date of the first application?—Mr. MACPHERSON: The only reason—and it is a very sound one—is that Parliament has decided otherwise.

Dentures for Ex-Service Men.

Mr. BRIANT asked the Minister of Pensions if he would state what arrangements were made for the supply of dentures to ex-Service men who required the same by reason of illness or injury sustained whilst on service; to whom application should be made; and if they were supplied free of cost to the men.—Mr. MACPHERSON replied: The Minister has arranged with a panel of dentists throughout the United Kingdom for the free supply of dentures to those ex-Service men who, as a result of illness or injuries due to service, require them. Application should be made by the man to his Local War Pensions Committee.—Mr. BRIANT: Does the right honourable gentleman know that Pensions Committees in some cases say that they cannot do anything for these men?—Mr. MACPHERSON: If the honourable gentleman will give me any case where there is difficulty I will look into it at once.—Dr. MURRAY: Who will determine whether the man is entitled to dental treatment? Will the Local War Pensions Committee be able to settle that question?—Mr. MACPHERSON: I think that must be decided beforehand. If he is entitled to a pension he is entitled to free dentistry.—Dr. MURRAY: Then he must go before a Pensions Board?—Mr. MACPHERSON: I think so.—Dr. MURRAY: Why should not the Pensions Board be in a position to order the treatment without all this circumlocutory delay?—Mr. MACPHERSON: I do not think there is any circuitous route at all. I think it is a very direct way. If he is entitled to a pension I have arranged for a panel of dentists throughout the country to which he can go. If he submits his claim to the Local War Pensions Committee every assistance will be given to him.—Mr. SPENCER: Is the right honourable gentleman aware that men who have contracted some form of disease have been ruled by local boards to have contracted it before service, and what can he suggest to obviate that?—Mr. MACPHERSON: That is so, but a man has a very fair trial. He has a full right of appeal on a question of entitlement to a tribunal, which is independent of the Ministry of Pensions.

FRIDAY, JULY 30TH.

Dangerous Drugs Bill.

The Dangerous Drugs Bill was read a third time.

Ex-Service Men in Asylums.

Brigadier-General SURTEES asked the Minister of Pensions if he would state how many ex-Service men were inmates of asylums in the United Kingdom; whether they were treated in the same manner as pauper lunatics; and what was the cost to the country of such ex-Service inmates.—Major TRYON (Parliamentary Secretary to the Ministry of Pensions)

replied: The number of disabled ex-Service men classified as Service patients is about 5000. As the charges for maintenance of these patients vary considerably in different parts of the country, it would entail more work than I feel justified in imposing on my staff to ascertain the total cost to the country.

TUESDAY, AUGUST 3RD.

Condemned Meat at Newcastle.

Mr. GRATTAN DOYLE asked the Food Controller if he had read the report of the corporation veterinary inspector of Newcastle-on-Tyne for the four weeks ending July 10th, 1920, relative to the quantities of meat received in that city which had been found to be unfit for human food; and, if so, if he could give any explanation of the state of affairs there disclosed.—Mr. McCURDY replied: I have read the report of the corporation veterinary inspector of Newcastle-on-Tyne for the four weeks ending July 10th. I find that during that period a certain quantity of home-grown beef was found to be tuberculous and accordingly condemned. A large quantity of imported meat was also condemned, consisting partly of offals which had been brought in on transshipment from the Continent on private account, and partly of carcasses also sent on private account which appear to have been unsound for some time. Certain cases of rabbits were also condemned, which formed part of surplus army stock for which it had been found impossible to effect a sale. I am satisfied that the utmost vigilance is being exercised by the sanitary authorities at Newcastle-on-Tyne, and the honourable Member may rest assured that the Ministry of Food is doing everything in their power to assist them.—Dr. ADDISON (Minister of Health) said that he was making inquiries as to the position in regard to Newcastle, and will communicate with the honourable Member.

Children from South-Eastern Europe.

Mr. RONALD McNEILL asked the Secretary for the Home Department whether the operations of the committee who were bringing to England children and young persons from Hungary and other parts of South-Eastern Europe were being conducted under his supervision and control; if he would say how many such children and young persons it was intended to bring to this country; whether stringent precautions were being taken to prevent the introduction of infectious disease; where and under what conditions were these immigrants being accommodated; whether any adults were being admitted with the children and young persons; and whether any similar hospitality and charity were being offered in England to children from allied countries who might be as much in need as children of late enemies.—Mr. SHORTT replied: The work of the committee is not supervised or controlled by me. 456 children from Vienna have already arrived and 400 more from Budapest are expected shortly. That is all I know of at present. Careful medical examination of the children before they start for this country is made under the supervision of a medical officer of the Ministry of Health, and on arrival they are placed in quarantine in a camp near Richborough. In due course they are distributed to various parts of the country, the whole process being supervised by the Ministry of Health. No adults are being admitted with the children. A Manchester committee has recently asked for and obtained permission to bring over a number of French children from the devastated areas of France for a period of recuperation in this country.

The Services.

ROYAL ARMY MEDICAL CORPS.

Major J. S. Dunne to be acting Lieutenant-Colonel.
Temp. Capt. A. Brown relinquishes the acting rank of Lieutenant-Colonel.

Temp. Capt. A. Farquhar relinquishes the acting rank of Major.
To be Captains: Capts. G. K. Maurice (from T.F.), D. McVicker (late temporary Captain, R.A.M.C.); Temp. Capt. A. E. Drynan, J. W. Malcolm, W. C. Connell; Lieuts. (Temp. Capts.) J. A. Cowan, J. P. Macnamara, J. W. Hyatt, T. Stanton, T. Parr, A. P. Draper, J. R. S. Mackay.

To be Lieutenants and to be Temporary Captains: Capts. R. R. Evans and F. K. Escrib (from Spec. Res.); Temp. Capt. J. L. Handy.

Hon. Capt. C. A. Hutchinson, late R. W. Kent R., to be Lieutenant.
Officers relinquishing their commissions:—Temporary Majors retaining the rank of Major: J. P. Campbell, R. Worth. Temporary Captains granted the rank of Major: H. H. O'Heffernan, D. C. McCabe-Dallas, D. Gillespie, P. Murphy, J. P. Mathie, A. Topping, (Acting Major) J. A. Mackenzie. Temporary Captains retaining the rank of Captain: J. A. Bateman, A. C. Greenwood, A. C. Wilson, F. C. Watson, R. C. De Lacey, G. B. McTavish, H. R. Hurry, A. M. Niven, G. Maclean, E. Tanton, A. J. C. Tingey, T. W. J. Childs, A. S. Sieger, A. W. C. Bennett, H. C. Hopkinson, B. G. H. Connolly, P. S. MacLaren, J. V. O. Andrews.

SPECIAL RESERVE OF OFFICERS.

Capt. A. H. Habgood relinquishes his commission and is granted the rank of Lieutenant-Colonel.

Officers relinquishing their commissions:—Capt. E. N. H. Gray. Captains retaining the rank of Major: F. Crosbie, J. Gossip. Captains retaining the rank of Captain: R. Chevassut, R. H. Yolland, J. H. Davison, A. D. Gorman, T. H. McLeod, W. H. Palmer, D. J. Thomas, J. Kinnear, W. W. Nicol, P. T. Jones, J. W. Bowman, E. G. Fiske, A. B. Dummere, D. Stewart, W. C. MacKinnon, L. Walker, J. N. Jamieson, A. Black, J. Liddell, E. V. Beale, A. O. Bolton, D. Cameron, W. M. Casper, C. A. Harvey, R. B. Hick, R. L. Robinson.

TERRITORIAL FORCE.

Major H. A. T. Fairbank resigns his commission and is granted the rank of Lieutenant-Colonel.

Capt. A. K. MacLachlan resigns his commission and is granted the rank of Major.

INDIA AND THE INDIAN MEDICAL SERVICE.

Lieut.-Col. H. B. Melville, Residency Surgeon, Kashmir, has proceeded on leave owing to ill-health. Lieut.-Col. McIver Smith officiates. Major C. A. Gourlay has been appointed Civil Surgeon of the 24 Parganas and Protector Emigration and Superintendent Emigration, Calcutta. Lieut.-Col. A. Leventon has been granted six months' leave. Lieut.-Col. E. L. Perry, Deputy Sanitary Commissioner, Punjab, is appointed Sanitary Commissioner, vice Major W. A. Justice, Madras Government. Capt. J. S. S. Martin to hold Civil Medical Charge of Roorkee, in addition to his own duties, vice Capt. J. Callonan, R.A.M.C. Major P. Gail, on reversion from military duties, has been appointed Civil Surgeon, Raibhaki, vice Dr. R. S. Ashe. Major A. E. J. Lister, Professor of Physiology, King George's Medical College, Lucknow, has been granted combined leave for eight months. Major W. Lethbridge has been granted an extension of leave for six months. Lieut.-Col. H. Smith, Amritsar, has been granted one year's leave. Capt. Charters has returned from military duty and is posted to Umbala.

I.M.S. Ex-Officer's Rank.

A Government communiqué announces that an officer in the I.M.S. holding a permanent or temporary commission whose service has been satisfactory throughout shall be granted permission to retain his rank on demobilisation. If, however, he held higher acting or temporary rank during the war for a minimum period of six months, or if his service on the active list terminated as the immediate result of sickness or wounds caused "in or by" the Service while holding the higher acting or temporary rank, he will be permitted to retain rank equivalent to such acting or temporary rank.

DEATHS IN THE SERVICES.

Surgeon-General William Gerard Don (retd.), who died at his residence, Canfield-gardens, N.W., on July 27th, in his eighty-fifth year, served as a medical volunteer in the flagship *Duke of Wellington* in the Baltic Fleet and at the battle of Sveaborg in 1855. He graduated M.D. at the University of Edinburgh in 1857, joined the Army Medical Service in the following year, and served in Central India during the Mutiny, being present at the actions with Tantia Topce at Rajpore and Belkara (mentioned in despatches). In 1882 he was employed in fitting out hospital ships for the Egyptian Expedition. For 17 years he was senior medical officer to the London Recruiting Staff. Surgeon-General Don, who retired in 1885, was president of the Caledonian Society of London and a life-governor of the Royal Scottish Corporation.

THE HONOURS LIST.

The following promotions and appointments of medical officers for valuable services rendered in connexion with operations in Afghanistan are announced:—

C.S.I.—Maj.-Gen. H. Hendley, I.M.S.
C.I.E.—Lt.-Col. H. D. Packer, R.A.M.C.; temp. Lt.-Col. J. F. Haswell, R.A.M.C.; Maj. A. F. Babonau, O.B.E., I.M.S.
C.B.E.—Lt.-Col. (acting Col.) H. Boulton, I.M.S.; Col. P. Carr-White, K.H.P.; Lt.-Col. J. G. Gill, D.S.O., R.A.M.C.
O.B.E.—Capt. (acting Lt.-Col.) P. B. Bharucha, D.S.O., I.M.S.; Capt. H. S. Blackmore, R.A.M.C.; Maj. C. E. Bulteel, I.M.S.; Maj. (acting Lt.-Col.) A. Cameron, I.M.S.; temp. Capt. P. J. De Sousa, I.M.S.; temp. Lt. B. N. Gupta, I.M.S.; Capt. (acting Lt.-Col.) J. P. Huban, I.M.S.; temp. Capt. R. W. Murphy, R.A.M.C.; Capt. R. B. Myles, R.A.M.C.; Capt. F. H. B. Norrie, R.A.M.C. (S.R.); temp. Capt. A. P. Pillay, I.M.S.; Capt. and Bt. Maj. C. Ryles, R.A.M.C.; Maj. (acting Lt.-Col.) W. W. Browne, R.A.M.C.
M.B.E.—Temp. Capt. Y. B. Ranade, I.M.S.
To be Brevet Lieut.-Col.—Maj. R. S. Kennedy, D.S.O., M.C., I.M.S.
To be Brevet Major.—Capt. G. A. Blake, R.A.M.C.; Capt. (temp. Maj.) T. A. Hughes, I.M.S.
D.S.O.—Capt. and Bt. Maj. (temp. Maj.) E. E. Doyle, I.M.S.
M.C.—Capt. J. E. Carpenter, R.A.M.C. (S.R.); Capt. D. F. Murphy, I.M.S.

CALEDONIAN MEDICAL SOCIETY.—The annual meeting of this society was held in the Prince Charlie Room of the Public Library, Derby, on July 24th, under the presidency of Dr. Rutherford Macphail. The society makes a practice of holding annual meetings alternately in England and Scotland, but no annual gathering had actually occurred since 1914. Conditions of membership are Celtic blood and the possession of a university degree. The society, which has a membership of 300 in addition to some 25 honorary members belonging to other professions, gives special attention to old Celtic literature in relation to medical science. Dr. Macphail took as the subject of his address "Derby and the 'Forty-five.'" The annual dinner was held the same evening, when the toast of the society was proposed by Dr. F. Milnes Blumer, Mayor of Stafford. The next annual meeting will be held in Edinburgh, under the presidency of Emeritus Professor William Russell.

Medical News.

UNIVERSITY OF CAMBRIDGE.—At recent examinations the following candidates were successful in the undermentioned subject:—

DIPLOMA IN MEDICAL RADIOLOGY AND ELECTROLOGY.

Part I., Physics and Electrotechnics.—William Wallace Boyce, John Prichard Bracken, Noel Hawley Michael Burke, Henry Warner Collins, George Eldridge Dyas, Thomas Garfield Evans, William Christopher Long, Geoffrey Trevor Loughborough, Hector Bruce Mackenzie, Thomas Marlin, Harry Carew Nott, Claude Mallinson Rigby, Charles Allen Robinson, Stanley Wilson Shields, Johan van Rooijen, Jocelyn Langton Waller, and Eva Muriel White.

Part II., Radiology and Electrology.—William Wallace Boyce, Henry Warner Collins, George Eldridge Dyas, Thomas Garfield Evans, Max Hermann Knoch, William Christopher Long, Geoffrey Trevor Loughborough, Hector Bruce Mackenzie, Thomas Marlin, Harry Carew Nott, Claude Mallinson Rigby, Charles Allen Robinson, Stanley Wilson Shields, Johan van Rooijen, Eva Muriel White, and Justina Augusta Wilson.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.—An ordinary Comitia was held on July 29th, Sir Norman Moore, the President, in the chair. The minutes of the Censor's Board were read, and it was resolved—

"That Frederick Arthur Pring be declared to be no longer a Licentiate of the College, and that he forfeit all rights and privileges, and that his name be removed from the list during the pleasure of the College."

The President announced the following appointments:—Dr. F. Parkes Weber, to deliver the new Mitchell Lecture for 1921; Dr. George Graham, to be Goulstonian lecturer for 1921; Dr. Thomas Lewis, to be Oliver Sharpey lecturer for 1921; Dr. Arthur Whitfield, to be Lumsian lecturer for 1921; Dr. R. O. Moon, to be FitzPatrick lecturer for 1921; and Dr. Gordon M. Holmes, to be Croonian lecturer for 1922.—A grant of £100 was made to Sir F. W. Mott from the Croonian Trust for his researches.—Dr. Eardley Lancelot Holland was admitted to the Fellowship.—The following candidates, having passed the required examinations, were admitted as Members of the College:—Dr. A. C. Alport, Dr. F. V. Bevan-Brown, Dr. G. K. Bowes, Dr. H. C. H. Bull, Mr. W. S. Dawson, Dr. G. B. Dowling, Dr. H. Gardiner-Hill, Dr. T. J. H. Hoskin, Dr. J. Inkster, Dr. J. Joffe, Dr. J. W. McNee, Dr. T. H. Oliver, Dr. R. J. Perkins, Dr. J. H. Sheldon, Dr. G. J. Sophianopoulos, Dr. A. T. Stanton, Dr. H. Stott, Dr. R. J. C. Thompson, Dr. A. P. Thompson, Dr. A. G. Williams, Dr. T. P. Williams, Dr. Irene Yates.—Licences to practise physic were granted to 85 candidates who had conformed to the by-laws and regulations and passed the required examinations.—Diplomas in Public Health were granted jointly with the Royal College of Surgeons to 35 candidates.—The report of the examiners for the Murchison scholarship was received, and the scholarship was awarded to Roland John Perkins. John Vernon Cannadine Braithwaite, *proxime accessit*, was awarded a special scholarship of ten guineas.

The following College officers and examiners were elected on the recommendation of the President and Council:—Censors: Dr. Hector W. G. Mackenzie, Sir John Rose Bradford, Sir James Galloway, and Dr. John Fawcett. Sir Dyce Duckworth, Dr. J. A. Ormerod, and Dr. Arnold Chaplin were re-elected as Treasurer, Registrar, and Harveian Librarian respectively. Dr. Raymond H. P. Crawford was elected to the Library Committee, and Dr. G. F. Blacker to the Council, in place respectively of Dr. Mackenzie and Dr. Fawcett, elected censors.—The Fellows newly elected to office having given their faith to the College, the President announced that he had awarded the Bisset Hawkins medal to Dr. W. H. Hamer, and that he had nominated Sir William Hale White to serve on a committee appointed by the Minister of Health to advise upon the control of therapeutic substances, which cannot be tested by direct chemical means.—Dr. Dawson Williams was appointed to represent the College on the governing body of Birmingham University in the place of the late Dr. Samuel West.

A report was received from Sir Humphry Rolleston and Mr. H. J. Waring, representatives of the Royal Colleges, upon their visit to the examination held at Philadelphia, May 19th–26th, 1920, by the National Board of Examiners. This was referred to the Committee of Management after the President had spoken in highly appreciative terms of it.—A complete account of the proceedings of the Committee of Reference was received from the chairman, Dr. Sidney Martin. The thanks of the College were accorded to Dr. Martin and to Mr. F. G. Hallett, who acted as secretary to the Committee.—A report, dated June 9th, 1920, was received from the Representative of the College on the General Medical Council upon the proceedings of the Council at the meeting held in May–June last.—The annual report of the Cancer Research Fund was received and the thanks of the College were accorded to the Executive Committee.—A

report from Sir George Savage concerning the Chelsea Physic Garden was received and entered on the minutes. Sir George Savage was reappointed a representative on the Committee of Management of the Chelsea Physic Garden.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—An ordinary Council meeting was held on July 29th, Sir Anthony Bowlby, President, in the chair.—Sir D'Arcy Power was readmitted to the Council.—A Report from the Court of Examiners for the diploma of Member was read, and diplomas of Membership were granted to 84 candidates mentioned in the report.—The Council elected Mr. Evelyn Sprawson, M.C., M.R.C.S., L.D.S., a member of the Board of Examiners in Dental Surgery.

Primary Examination for the Fellowship.—The Council recommended that in future one paper of four questions be set in anatomy, and in physiology one paper of six questions, four of which must be answered. (This was in pursuance of a recommendation from the Board of Examiners. At the present time two papers in anatomy and two papers in physiology are set, each containing four questions, of which the candidate must answer only two. This plan was introduced in 1913 in consequence of recommendations from the examiners and teachers of that time. Formerly there was one paper in each subject, each containing four questions, of which not more than three had to be answered.)

A letter from the dean of the Royal Dental Hospital of London School of Dental Surgery was read, reporting the following resolution adopted by the Medical Committee of the school:—

That the Medical Committee of the Royal Dental Hospital has recently considered in detail the education of the dental student, and is of the opinion that it would be a great advantage if students could be allowed to present themselves for examination in anatomy, physiology, and dental anatomy at the end of the first year of study at a general hospital.

The matter was referred to the Dental Board of Examiners to consider.

A report of the Committee of Management was read, approved, and adopted, recommending that—

(a) The following be added to the list of institutions recognised for the instruction in chemistry and physics—viz., the College, Bishop's Stortford; Victoria Institute, Worcester.

(b) The following be added to the list of institutions whose graduates in Medicine are admissible to the Final Examination of the Examining Board in England under the conditions of Par. IV., Section III. of the regulations—viz., the University of Virginia, Charlottesville, U.S.A.

(c) Sir Charles Ballance, K.C.M.G., C.B., M.V.O., be appointed visitor to the examinations of the Egyptian School of Medicine for the next period of examination.

A letter was read from Sir John Rose Bradford reporting the transfer of certain stocks into the name of "The Royal College of Surgeons of England" in pursuance of the undertaking of the College to become the trustees and administrators of the Lister Memorial Fund. The provisions of the trust, as we have already noted (THE LANCET, July 24th, p. 223), are: (1) That out of the general fund a sum of £500, together with a bronze medal, be awarded every three years, irrespective of nationality, in recognition of distinguished contributions to surgical science, the recipient being required to give an address in London under the auspices of the Royal College of Surgeons. (2) That the award be made by a committee constituted as follows: Two members nominated by the Royal Society; two members nominated by the Royal College of Surgeons of England; one member nominated by the Royal College of Surgeons in Ireland; one member nominated by the University of Edinburgh; one member nominated by the University of Glasgow. (3) That any surplus income of the general fund, after providing for the erection of a monument, and after defraying administering expenses, be either devoted to the furtherance of surgical science by means of grants or be invested to increase the capital of the fund.

ROYAL COLLEGES OF PHYSICIANS OF LONDON AND SURGEONS OF ENGLAND.—At a meeting of Comitia of the Royal College of Physicians and of the Council of the Royal College of Surgeons on July 29th diplomas of L.R.C.P. and M.R.C.S. were respectively conferred upon 85 candidates who have passed the Final Examination in Medicine, Surgery, and Midwifery of the Conjoint Board, and have complied with the by-laws of the Colleges. The following are the names and medical schools of the successful candidates:—

A. N. Aitken, Rush Medical Coll.; H. S. Baker, St. Bart.'s; W. J. Birchall, Liverpool Univ.; S. Blackman, London; T. L. Bonar, Cambridge and St. George's; J. P. Brown and G. N. Campey, Liverpool; L. E. R. Carroll and G. W. Cheater, Charing Cross; H. S. Cohen, London; Sarah Annie Cooper, Charing Cross; D. Crawford, Cambridge and St. Bart.'s; J. W. Crawshaw, Manchester; F. W. Crook, Guy's; K. V. Deakin, Manchester; S. N. Deboo, Bombay; G. L. J. A. de Rynck, Univ. Coll.; W. D. Doherty, Guy's; T. A. J. Duff, Toronto; R. S. Fawcett, St. Bart.'s; J. Flanagan, Liverpool; Ada Marion Freeman, King's Coll.; Blanche Sutton Gardner, Royal Free; A. D. Gill, Birmingham; C. I. C. Gill, Cambridge and

Guy's; Doris Elsie Florence Goodall, Birmingham; E. E. D. Gray, Guy's; Hilda Trelloggen Haggett, Royal Free; Gertrude Eleanor Harre, St. Mary's; H. A. Harris, Univ. Coll.; F. Heber, London; L. W. Hefferman, Middlesex; Sylvia Kema Hickson, Manchester; G. F. W. Howorth, Middlesex; H. V. Jackson, Bristol; F. J. Jauch, Middlesex; Marjorie Mary Jefferson, Manchester; Doris Eleanor Parker Jolly, King's Coll.; Silas G. Jones, Liverpool; Dorothy Maud Kemp, Royal Free; A. W. Kirkham, Manchester; J. N. Laing, St. Bart.'s; P. T. Liang, Cambridge and St. Thomas's; H. A. Lomax, Manchester; Mary Alice McHugh, Liverpool; G. J. W. McMichael, Univ. Coll.; R. T. McKee, London; Dora Mason, Royal Free and St. Mary's; W. F. Matthews, King's Coll.; L. B. Maxwell, St. Thomas's; Eva Morton, Royal Free; L. Moss, Guy's; Annie Agnes Muir, Liverpool; B. P. Nanavati, Bombay and London; C. W. Narbeth and D. G. F. Moore, St. Bart.'s; D. J. P. O'Meara, Guy's; R. Y. Paton, Cambridge and St. Mary's; P. H. Perera, Ceylon and London; J. Posner, Dublin; G. H. Potter, Liverpool; M. R. Rana, Bombay and Middlesex; G. K. Reeves, Guy's; M. H. Renall, St. Bart.'s; E. L. Robert and L. C. Rogers, Middlesex; W. R. Sadler, St. Bart.'s; J. A. P. Shaw, Cambridge and St. Thomas's; G. Sheehan, Manchester; F. D. Spencer, Birmingham; A. D. Stoute, Boston and Westminster; P. W. Symons, Middlesex; H. Tomlinson, Manchester; B. M. Tonkin, Guy's; M. Tree, London; Edith Helen Trimmer, St. George's; N. S. B. Vinter, St. Bart.'s; R. P. Wanless, Durham and Oxford; Helena Jane Webster, Westminster; C. H. Whittle, Cambridge and King's Coll.; Dorothea Compston Wigfield, Royal Free; W. R. Williams, Liverpool; and S. Wright and C. R. Young, Middlesex.

DIPLOMA IN PUBLIC HEALTH.

The Diploma in Public Health has been granted to the following 35 successful candidates:—

Lewis Anderson, King's Coll.; Kaikhushroo Maneckji Bharucha, Bombay and Univ. Coll.; Gordon Thomas Calthrop, Cambridge and Univ. Coll.; Arthur Skelding Cane, Cambridge and St. Bart.'s; Thomas Philips Cole, Guy's and King's Coll.; Delphine Gertrude D'Abreu, Univ. Coll.; Cuthbert Esquire Dukes, Edinburgh and Univ. Coll.; Reginald Oliver Eades and Hugh Alderson Fawcett, Univ. Coll.; Hubert John Burgess Fry, Oxford and Univ. Coll.; Andrew Radburne Fuller, St. Mary's and Univ. Coll.; Arthur Henry Haggood, Cambridge and London; Ronald Nelson Hunter, London and Middlesex; John Herbert Jordan, Cambridge and Middlesex; John du Plessis Langrishe, Dublin; Edward Richardson Lovell, Middlesex; Herbert Cubitt Lucey, Guy's; James Macalister Mackintosh, Glasgow and King's Coll.; Charles Arthur Mason, Edinburgh and Univ. Coll.; Edgar William Matthews, King's Coll.; William John Moir, Aberdeen and Univ. Coll.; Framroz Nanabhooy Moos and Dennis Salmon Page, Univ. Coll.; Wyndham Parker, Edinburgh and Univ. Coll.; Parmanand, Punjab and Univ. Coll.; Arthur Borland Porteous, St. Mary's; William Bentley Purchase, Cambridge, London, and Univ. Coll.; Maitland Radford, Univ. Coll.; Rowan William Revell, Middlesex; Frederick Emilius Roberts, St. George's; Arthur Burch Rosher, Charing Cross; Hugh Stott, Guy's; Wilfrid Reginald Taylor, St. Mary's; John Newton Webb, Adelaide and Univ. Coll.; and Augustus Joseph Wernet, Royal Naval College, Greenwich.

ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH, ROYAL COLLEGE OF SURGEONS OF EDINBURGH, AND ROYAL FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW.—The following candidates have passed the Triple Qualification Examination:—

THIRD EXAMINATION.

Edward James Allan, Jemina Marianna M'Kechnie Calder, James M'Nie Campbell, Dominic Ciantar, William Arthur M'Kie Gibson, William Gray, Gerrit Johannes Lamprecht, Ian Fleming M'ash, Saros Ardishair Dadabhai Naoroji, James Readdie, Sidney Sack, Joseph Alfred Henry Sykes, Enid Anne Williams, and Lillian Mary Williams.

FINAL EXAMINATION.

George Green, James Stewart Durward, Muriel Keyes, William Ewart de Silva, William Barton, Benjamin Belilovsky, Frederic James Stevenson, Jesse Hayna Crawford, Agnes Macilwraith Hill, Karthegea Ponniah, Andrew Gold, Arthur Henry Jacobs, Frank Arthur Smorffitt, Jessie Melville Lyell Wright, Percival Charles Holden Homer, Sidney Scott Sumner, William M'Mullan, Israel Goldberg, Oswald Brunlees, Douglas Chiene Scotland, Thomas Poole, James M'Glashan, John Stevenson, May Constance Boughton-Leigh, Thomas Hardie, and Thomas Arnoldus du Toit.

UNIVERSITY OF BRISTOL.—The Markham Skerritt prize, awarded every three years to that medical member of the University of Bristol who in the opinion of the board of the Faculty of Medicine has in the previous three years published the best original work in any branch of medical science, has recently been awarded to Professor F. H. Edgeworth and Mr. E. W. Hey Groves. During the war no award was made.

The first post-graduate course held under the joint auspices of the Council of the College of Medicine, the honorary medical and surgical staff of the Royal Victoria Infirmary, Newcastle-on-Tyne, and the British Medical Association (North of England) has just been completed. The course was well attended and has been in every way a complete success. This success and the wish expressed by a large number of practitioners has encouraged the committee to continue the courses during the coming winter. The syllabus, which is under consideration at present, will be a revised and extended one, and a further announcement will appear in due course.

LONDON HOSPITALS: DISTRIBUTION OF SURPLUS RED CROSS FUNDS.—The Joint Finance Committee of the British Red Cross Society and the Order of St. John of Jerusalem, having invited the King's Fund to undertake the distribution of £250,000 out of the surplus funds at the disposal of the Committee amongst London hospitals, this has now been done upon conditions similar to those on which the Joint Committee had already made a distribution of surplus funds amongst hospitals outside London.

Certain conditions were to be attached to this distribution, e.g.:—

(a) That the distribution should be confined to hospitals in the London area that could and would treat ex-sailors or ex-soldiers.

(b) That it should take the form of capital grants in aid of definite schemes of extension or improvement that would directly or indirectly increase the facilities for the treatment of ex-Service men, no part of it being available for maintenance or for the payment of debts.

(c) That before any grant was actually paid over the scheme must be mature.

These conditions exclude from the special distribution certain hospitals, such as those providing for women and children only, eligible for the Fund's ordinary distribution and include others ineligible under the ordinary rules. Applications were considered from 64 hospitals in respect of 81 schemes, and grants were recommended to 49 of these in respect of 54 schemes. The amount and purpose of the particular grants are as follows:—

Acton Hospital, £2500, extension, new out-patient department.
Beckenham Cottage Hospital, £2250, extension, new operating theatre.

Charing Cross Hospital, £1250, improvements to X ray department, nurses' home.

City of London Hospital for Diseases of the Chest, Victoria Park, £4000, surgical block and sanitary and other improvements.

Croydon General Hospital, £1000, additional nurses' accommodation (subject to the provision of fire exit).

Dreadnought Hospital, £7000, erection of sanatorium for tuberculous seamen at Bramshot, Hants.

East Ham Hospital, £9000, rebuilding as general hospital.

Finchley Cottage Hospital, £1750, extension, new administration block.

French Hospital, £2000, enlarged nurses' and servants' quarters, enlarged out-patient department, additional beds, and other improvements; in the order stated.

Great Northern Central Hospital, £15,500, new nurses' home, new boilers, and new kitchen; in the order stated.

Guy's Hospital, £11,000, nurses' home extension and special out-patient departments.

Hampstead General Hospital, £1000, electrical and physical departments, and other improvements.

Hendon Cottage Hospital, £600, new operating theatre, X ray room, and improved nurses' accommodation.

Hornsey Cottage Hospital, £1500, extension, new operating theatre.

Hospital for Consumption, Brompton, £7000, extension of sanatorium at Frimley.

Hospital for Diseases of the Throat, £2500, rebuilding of amalgamated hospital.

Hospital for Epilepsy and Paralysis, £2000, extension of out-patient department.

King's College Hospital, £1000, equipment of wards, theatres, and special departments.

London Homoeopathic Hospital, £1250, improvements to boilers, lighting, lifts, heating.

London Hospital, £3500, new massage and electrical departments.

London Jewish Hospital, £1250, extension of in-patient department, kitchen, operating theatre.

London Temperance Hospital, £6000, new nurses' accommodation, improvements to isolation ward; provided that the Hospital Committee are satisfied that the ward already vacant and the ward vacated by the scheme can both be opened to patients.

Middlesex Hospital, £2700, new night nurses' home.

Middlesex Hospital Cancer Charity, £300, new night nurses' home.

Mildmay Mission Hospital, £2500, fire escape staircase, enlarged nurses' home, new operating theatre, and other improvements; on condition that the staircase is put in hand immediately.

Miller General Hospital for South-East London, £15,000, extension, new nurses' home, kitchen, and out-patient, casualty, and pathological departments.

National Hospital for Diseases of the Heart, £2000, extension of out-patient department.

National Hospital for the Paralysed and Epileptic, £1000, provision of out-patient operating room, and improvements to in-patient theatre.

Nelson Hospital for South Wimbledon, £2500, extension, additional nurses' rooms.

Norwood Cottage Hospital, £300, additional rooms and new X ray apparatus.

Passmore Edwards Hospital for Willesden, £8000, extension as general hospital.

Poplar Hospital, £6000, improved casualty department.

Prince of Wales's General Hospital, £10,000, extension, additional nurses' rooms.

Queen Mary's Hospital for the East End, £12,000, new nurses' home and in-patient operating theatre, subject to the submission of block plan for ultimate utilisation of complete site.

Royal Free Hospital, £8500, nurses' home and extension, in the order stated.

Royal National Orthopaedic Hospital, £24,000, extension of out-patient department, X ray, electrical, exercise and Swedish drill rooms, nurses' bedrooms.

St. Bartholomew's Hospital, £24,000, new nurses' home.

St. John's Hospital, Lewisham, £1250, new out-patient department.

St. John's Hospital for Diseases of the Skin, £400, new nurses' accommodation.

St. Mark's Hospital, £600, new nurses' rooms.
 St. Paul's Hospital for Skin, &c., £1500, new hospital in Endell-street.
 St. Peter's Hospital for Stone, £600, new nurses' rooms, X ray rooms.
 St. Thomas's Hospital, £2500, enlargement of nurses' dining room.
 University College Hospital, £500, re-equipment of radiographic and electrical department.
 West End Hospital for Nervous Diseases, £2500, removal to Regent's Park, improved nurses' accommodation at Regent's Park, and reconstruction of out-patient department at Welbeck-street. Of the grant of £2500, £500 is subject to the carrying out of the scheme for the provision of a new nurses' home at Regent's Park.
 Western Ophthalmic Hospital, £2000, reconstruction and extension.
 West London Hospital, £8000, new out-patient department.
 Wimbledon Hospital, £1500, new nurses' home, and resident medical officer's quarters.
 Woolwich War Memorial Hospital, £25,000, building of general hospital.

In making their allotment the Distribution Committee of the King's Fund has particularly borne in mind the importance of not unduly encouraging the provision of additional beds, and it was ultimately decided that much the larger proportion of the gift should be devoted to improvements involving only comparatively small additional expenditure on maintenance. The amount devoted to schemes other than bed extensions has been used to assist numerous improvements, which are no less important from the point of view of the treatment of ex-Service men, and often of greater urgency. They include the enlargement of out-patient accommodation, the improvement or equipment of massage, electrical, and X ray departments, new operating theatres, and the provision of better accommodation for nurses. The Distribution Committee had no hesitation in regarding nurses' homes as improvements within the scope of the special distribution.

The distribution is the subject of comment in a leading article in our present issue.

A POST-GRADUATE WEEK AT OXFORD.—A post-graduate course is to be held in the Radcliffe Infirmary and County Hospital at Oxford, conducted by members of the staff, from Friday, Oct. 1st, until Saturday, 9th. Those attending the course will be asked to contribute a nominal subscription of 10s. towards the incidental expenses. A social dinner will form part of the arrangements. Further particulars from Dr. H. A. B. Whitelocke, Radcliffe Infirmary, Oxford.

THE National Council for Combating Venereal Diseases has a vacancy for a medical man on the Commission which it is proposed to send to the East Indies and China in the autumn. Fuller particulars will be found in our advertising columns.

THE Department of Scientific and Industrial Research has now established four Subcommittees to assist the Radio-Research Board in the investigation of certain problems in connexion with the work of the Board. The Board and its Subcommittees are strongly constituted, the latter dealing with the propagation of wireless waves, atmospherics, directional wireless, and thermionic valves.

KING'S COLLEGE HOSPITAL MEDICAL SCHOOL (UNIVERSITY OF LONDON).—Dr. A. C. D. Firth has been appointed Tutor to Cambridge Students, Dr. Raymond Crawford Tutor to Oxford Students, and Dr. J. A. Drake Demonstrator in Dermatology and Sub-Dean of the Medical School. A "Burney Yeo" Entrance Scholarship of £80 has been awarded to Mr. F. W. Furniss, B.A., of Downing College, Cambridge.

EASTERN COUNTIES CENTRE FOR ARTIFICIAL LIMBS.—The Ministry of Pensions has established a branch centre for the fitting of artificial limbs for ex-soldiers and sailors living in the Eastern Counties. A large house called Fernhill, standing in its own grounds in a suburb of Norwich, has been utilised. It had been used during the war as a military hospital, and is well adapted for its present purpose. Beds are available for 30 pensioners, and the ex-soldier or ex-sailor who requires an artificial leg stays for 14 to 16 days while his new limb is being made and fitted. There is a resident surgeon who superintends the fitting from a surgical point of view. A member of the firm of Messrs. Charles Salmon and Sons, of London, who has been carrying out the same work in France, is in charge of the whole process of making and fitting in a series of workshops equipped for the purpose. The "trees" of the legs are made of willow, obtained near Thetford. The Norfolk willow is specially suitable on account of its lightness and close grain. The rough trunks are cut into suitable lengths, a large hole being bored through the centre of each, and are then left in a dry shed to season. Though there is a standard pattern, each artificial leg is made to match the remaining sound leg, casts being taken for the purpose. Most of the men have already had artificial legs made in France, and are now in need of new ones. Since the opening of the depot two months ago about 120 men have been supplied. Artificial arms are not at present made in the depot.

THE LATE DR. E. J. TULK-HART.—Eugene John Tulk-Hart, M.D. Durh., M.R.C.S., L.S.A., who died rather suddenly on July 28th, at the age of 73 years, was one of the oldest medical practitioners in Brighton, where his kindly disposition and sympathetic interest had secured for him a large circle of friends. He retired from practice some years ago in favour of his son.

THE PORTRAIT OF SIR MICHAEL FOSTER.—The portrait of Michael Foster, recently presented by his son, Dr. Michael Foster, to the National Portrait Gallery, was painted by the Hon. John Collier in the autumn of 1906, and is a striking presentment of the great physiologist. Michael Foster sat for the portrait at the request of the artist, who afterwards gave him the picture in token of the long and unbroken friendship existing between Foster and Huxley, Collier's father-in-law. The portrait was exhibited at the Royal Academy in 1907, the last sitting by the distinguished subject having taken place only a week before his death. A replica of the head was given by request by Mr. Collier to the Royal Society, in whose rooms it now hangs in memory of an extended and distinguished secretaryship. At Lady Foster's death the original portrait passed into the possession of Dr. Michael Foster, with the request that it should be presented to the National Portrait Gallery, a request that was carried out by Dr. Foster immediately on his return from active service in France in 1919. Not only Michael Foster's many friends, and large body of distinguished and attached students, but all the medical profession will recognise that the public acknowledgment of his great worth, thus obtained, has been well deserved.

THE CHARTERED SOCIETY OF MASSAGE AND MEDICAL GYMNASTICS.—This amalgamation of the Incorporated Society of Trained Masseuses and the Institute of Massage and Medical Gymnastics has been formed under Royal Charter for the purpose of affording protection to the profession of massage and to its registered members. It has the following programme:—To improve the training and status of masseuses and masseurs; to provide and supervise independent examinations; to set up registers of persons qualified to practise; to arrange post-graduate courses, lectures, and conferences; to supply work for members under registry regulations; and to work in all ways for the advancement and general welfare of the profession. Registration with the Chartered Society is open to all certificate holders of the Incorporated Society and of the Institute. Test examinations will be set up for the benefit of masseuses and masseurs of experience, holding certificates other than the above-mentioned, who wish to register with the Chartered Society. Forms of application for registration and all information can be obtained from the offices of the society, 157, Great Portland-street, W.1. The Chairman of Council of the Chartered Society is Sir E. Cooper Perry, and the Queen has consented to become Patroness.

THE LATE DR. J. NEEDHAM.—Joseph Needham, whose strenuous work in army hospitals during the war impaired his health, died on August 2nd, aged 67. Educated at the London Hospital and at Aberdeen, he won a London Hospital medical scholarship in 1875, in which year he qualified with the M.R.C.S. Eng. Four years later he graduated at Aberdeen University M.B., C.M., taking the highest honours and special honours for a graduation thesis, and in the next year, 1880, became a Member of the Royal College of Physicians of Edinburgh. After holding house appointments at the London Hospital and becoming assistant to the professor of anatomy in the University of Aberdeen, he was appointed demonstrator of histology at the London Hospital Medical College and at the London School of Medicine for Women. He was anaesthetist to the 3rd London General Hospital and to the Kensington Red Cross (Weir) Hospital, medical officer to the Education Department of the London County Council, and surgeon to the Metropolitan Police.

CENTRAL MIDWIVES BOARD.—A special meeting of the Central Midwives Board was held at Queen Anne's Gate Buildings, Westminster, on July 22nd, with Professor H. Briggs in the chair, the chairman of the Board, Sir Francis Champneys, Bart., being absent through illness. This is the first occasion since the Board was first constituted on which the chairman has been absent. Two midwives were struck off the roll; one was cautioned and in other cases sentence was postponed, the following charges, amongst others, having been brought forward:—

That being in attendance at a confinement and the child suffering from inflammation of or discharge from the eyes, and continuing so to suffer, the midwife did not explain that the case was one in which the attendance of a registered medical practitioner was required, as provided by Rule E.21 (5), and she discontinued her attendance at a time when the child was so suffering as aforesaid. Medical aid having been sought for a patient the midwife neglected to notify the local supervising authority thereof, as required by Rule E.22 (1) (a), and she did not keep her register of cases, as

required by Rule E. 24. A child suffering from convulsions and dangerous feebleness and the midwife having explained that the case was one in which the attendance of a registered medical practitioner was required, she neglected to hand to the husband or the nearest relative or friend present the form of sending for medical help, properly filled up and signed by her, in order that this might immediately be forwarded to a medical practitioner or to an approved institution, as required by Rule E. 20 and 21 (5). A child having died before the attendance of a registered medical practitioner, the midwife neglected to notify the local supervising authority thereof, as required by Rule E. 22 (1) (b), and she did not at each visit record the pulse and temperature of the patient in a notebook or on a chart carefully preserved, as required by Rule E. 14. A presentation being other than the uncomplicated head or breech, the midwife did not explain that the case was one in which the attendance of a registered medical practitioner was required, as provided by Rule E. 21 (3); she did not stay with the patient after the commencement of the second stage of labour until the expulsion of the placenta and membranes, as required by Rule E. 7, and she neglected to pay to the patient a sufficient number of visits to satisfy the requirements of Rule E. 12. A case being one of puerperal fever or other condition supposed to be infectious, the midwife neglected to notify the local supervising authority that she was herself liable to be a source of infection, as required by Rule E. 6, E. 22 (1) (e), and E. 23, Form (e). Being suspended from practice by the local supervising authority for the purpose of preventing the spread of infection under Rule F. a midwife during the period of suspension paid visits to the maternity patients upon whom she had been in attendance at the date of such suspension.

THE LATE DR. F. J. H. BATEMAN.—Francis John Harvey Bateman, who died from heart failure while about to leave his residence for a holiday at Torquay, was 51 years of age, and was the son of the late Sir Frederick Bateman, M.D. Educated at Norwich Grammar School and at Pembroke College, Cambridge, he subsequently studied medicine at Edinburgh and Paris. After graduating M.B., C.M. at Edinburgh in 1898 he held resident posts at the Royal Infirmary in that city and at the Leith Hospital. He graduated also B.A. and M.A. at Cambridge in 1890 and 1901 respectively, proceeding to the M.D. Edinburgh in 1905. For a time he acted as assistant medical officer to the West Riding Asylum, Wakefield, and later went to Paris as resident medical officer to the Hertford British Hospital, and worked while there at the Pasteur Institute and at the French hospitals. Dr. Bateman was a vice-president of the Medical Society of London, a Fellow of the Obstetrical Society, a member d'Alliance Franco-Britannique, and a J.P. for the County of London. Among his appointments were those of medical officer to the Blackheath and Charlton Hospital, the Belmont Home for Ladies, the Dartmouth Home for Crippled Boys, Blackheath, and the St. Dunstan's Annexe for Blind Soldiers, Blackheath, while he was also medical adviser to the Blackheath High School.

ROYAL MEDICAL BENEVOLENT FUND.—At the last meeting of the committee, held on July 13th, 19 cases were considered, and £202 5s. voted to the applicants. The following is a summary of some of the cases relieved:—

Daughter, aged 60, of M.R.C.S. Eng. who practised at Marske-by-the-Sea and died in 1869. Applicant's only income is £28 a year from investments. She acts as general help in a home in return for food and fire. She suffers from chronic ill-health, and has had several operations. Her invalid sister lives with her, and she is quite incapable. Voted £10 in two instalments.—Widow, aged 64, of M.D. Mast Surgeon who practised in Jamaica and died in 1889. Applicant's only income is £54 16s. from another charity. She lives alone, and friends pay the rent. Cannot manage at present owing to the high cost of living. Voted £5.—Daughter, aged 50, of M.D. Dub. who practised at Douglas, Isle of Man, and died in 1882. Suffers from ill-health and is unable to work. She receives £50 from friends and £7 10s. from investments. Shares home with a friend, and pays part rent. Asks for further help, owing to the high cost of living. Relieved five times, £22. Voted £5.—Daughter, aged 70, of M.R.C.S. Eng. who practised at Buxton and died in 1878. Applicant is a trained nurse, but cannot earn much now on account of her advanced age. She has no other income but what she earns, and lives with her sister, who has to keep her. Relieved twice, £30. Voted £18 in 12 instalments.—Widow, aged 71, of M.D. Glasg. who practised at Dennistoun and died in 1876. Her only income is £20 from another charity. She lives with her married daughter, who can scarcely afford to keep her. She is crippled with rheumatism. Relieved six times, £78. Voted £18 in 12 instalments.—Widow, aged 59, of F.R.C.S. Edin. who practised in London and died in February, 1919. Applicant's husband had received help from the Fund. On the death of her husband she took a post as temporary clerk at £2 a week, but has now had to give this up, and asks for help until she obtains another post. No other income. Rent 8s. a week. Relieved once, £5. Voted £5. Subscriptions may be sent to the honorary treasurer, Sir Charters J. Symonds, at 11, Chandos-street, Cavendish-square, London, W.1.

Medical Diary.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

LONDON HOSPITAL MEDICAL COLLEGE.

MEDICAL UNIT, in the Clinical Theatre of the London Hospital, E.

A Course of Twelve Lectures on Neurology, open to Students and Graduates of the London Hospital and other Schools:—

TUESDAY, August 10th.—2 P.M., Lecture IX:—Dr. Riddoch: Disorders of Reflex Functions from Lesions of the Spinal Cord.

WEDNESDAY.—2 P.M., Lecture X:—Dr. Thompson: Symptoms and Causes of Paraplegia.

WEST LONDON POST-GRADUATE COLLEGE, West London Hospital, Hammersmith, W.

MONDAY, August 9th.—12.15 P.M., Dr. Burnford: Pathological Demonstration. 4.30 P.M., Mr. D. Armour: Subphrenic Abscess.

TUESDAY.—12 noon, Mr. T. Gray: Demonstration of Fractures, &c. 4.30 P.M., Mr. Banks Davis: Clinical Lecture:—II., Throat and Ear.

WEDNESDAY.—11.30 A.M., Mr. MacDonald: Demonstration of Cystoscopy. 2.30 P.M., Mr. D. Armour: Demonstration of Surgical Cases.

THURSDAY.—10.30 A.M., Dr. Simson: Gynaecological Demonstration. 4.30 P.M., Mr. B. Harman: Employer's Liability in Eye Injuries.

FRIDAY.—12.15 P.M., Dr. Burnford: Applied Pathology. 4.30 P.M., Mr. D. Buxton: Common Diseases and Injuries affecting the Buccal Cavity, their Recognition and Treatment.

SATURDAY.—12 noon, Mr. N. Sinclair: Surgical Diseases of the Abdomen.

Daily:—10 A.M., Ward Visits. 2 P.M., In-patient, Out-patient Clinics and Operations.

MALE LOCK HOSPITAL, Dean-street, W.

MONDAY, August 9th, WEDNESDAY, AND FRIDAY.—5 P.M., Dr. C. Russ: Demonstration of the Treatment of Gonorrhœa by Electrolysis.

CANCER HOSPITAL, Fulham-road, S.W.

Clinical Lectures on the Diagnosis and Treatment of Cancer.

TUESDAY, August 10th.—4.30 P.M., Mr. R. H. J. Swan: Cancer in the Urinary Tract.

FRIDAY.—4.30 P.M., Dr. A. Leitch: How Cancer Spreads.

Appointments.

Successful applicants for vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to THE LANCET Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.

McINTOSH, T. S., M.D. Edin., has been appointed Medical Officer of Health for Hendon.

SHATTOCK, C. E., M.D., M.S., F.R.C.S., Assistant Surgeon to the Royal Free Hospital.

SINCLAIR, N. F., F.R.C.S. Edin., Assistant Surgeon to the West London Hospital.
SMITH, E., M.D. Lond., Coroner for North-East District of London.
Certifying Surgeons under the Factory and Workshop Acts:
GAYNOR, G. C., M.B., B.Ch. N.U.I. (Wymondham); ARMSTRONG, C. (Dulais Valley).

Vacancies.

For further information refer to the advertisement columns.

Ashton-under-Lyne Union.—Asst. Med. Supt. and M.O. £368 10s.
Barnsley, Beckett Hospital and Dispensary.—Sen. H.S. £250.
Battersea General Hospital (Incorporated), Battersea Park, S.W.—Third Res. M.O. £200.
Bengal, University of Dacca.—Chair of Physical Education. Rs. 9000 to Rs. 12,000.
Birmingham General Dispensary.—Res. M.O. £400.
Birmingham General Hospital.—Res. M.O. £155. Also Obst. H.S., H.S., and Cas. H.S. £100 each. Also Res. Anæsth. £100. Also H.S. £125.
Birmingham University.—Lect. in Physiology. £250. Demonstrator in Pathology. £350.
Blackpool, Victoria Hospital.—H.S. £300-£350.
Bournemouth, Royal Victoria and West Hants Hospital.—Res. M.O. £200.
Bristol Eye Hospital.—H.S. £150.
Cancer Hospital, Fulham-road.—Asst. P. and Med. Reg. £250.
Chester Royal Infirmary.—H.P. £150.
Colonial Service.—M.O.'s for West African Medical Staff, Government Service in Malaya, East African Protectorates, West Indies (including British Guiana), Fiji, and the Western Pacific, &c.
Coventry Education Committee.—Two Sch. Dentists. £500.
Derby Borough Mental Hospital.—Asst. M.O. £350.
Derby County Borough Education Committee.—Asst. Sch. M.O. £500.
Dreadnought Hospital, Greenwich.—H.S. and H.P. £100.
Fulham Metropolitan Borough.—M.O. for Infant Welfare Centres. £2 2s. per session.
Gartnavel, Glasgow Royal Asylum.—Asst. M.O. £300.
Hertford County Hospital.—H.S. £200.
Hospital for Consumption and Diseases of the Chest, Brompton.—H.P.
Hove, Carr-Burton Memorial Hospital, Sackville-road.—Res. M.O. £250.
Isle of Ely County Council.—Clin. Tuberc. O. and Asst. M.O.H. and Sch. M.O. £600.
Keighley Borough Education Committee.—Female Asst. M.O. £500.
King's Lynn, West Norfolk and King's Lynn Hospital.—Res. M.O. £150.
Leasowes Hospital for Children, Cheshire.—Jun. M.O. £200.
Leavesden Mental Hospital, King's Langley, Herts.—Jun. Asst. M.O. £515.
Leicestershire and Rutland Mental Hospital, Narborough, near Leicester.—Jun. Asst. M.O. £300.
Lincoln County Hospital.—Jun. H.S. £150.
Liverpool, David Lewis Northern Hospital.—Two H.P.'s and Three H.S.'s. £120.
Liverpool, Fazakerley Sanatorium.—Asst. Res. M.O. £300.
Liverpool, Royal Children's Hospital.—Hon. P. and Hon. Asst. S.
Liverpool, Royal Southern Hospital.—Two H.P.'s and Three H.S.'s. £100.
Liverpool School of Tropical Medicine.—Three Medical Men for Clinical and Research Work in Tropical Medicine.
London County Council Mental Hospital Service.—Asst. M.O.'s. £200. Also Radiographer, £105.
Maidstone, Kent County Mental Hospital.—Jun. Asst. M.O. £300.
Maidstone, West Kent General Hospital.—H.S. £250.
Manchester, Ancoats Hospital.—H.S. £150.
Manchester, Barnes Convalescent Hospital, Cheadle.—Res. M.O. £300.
Manchester Children's Hospital, Pendlebury, near Manchester.—Two Res. M.O.'s. £150.
Manchester, Crossley Sanatorium, Delamere Forest, Cheshire.—Asst. M.O. £350.
Manchester, Hulme Dispensary, Dale-street.—H.S. £400.
Manchester Royal Infirmary.—Res. M.O. £250.
Mile-End Old Town, Hamlet of.—Second Asst. M.O. £300.
Miller General Hospital for South-East London.—H.S. £150.
National Council for Combating Venereal Diseases.—Medical Member of Commission to East Indies and China.
Newcastle-upon-Tyne Education Committee.—Dental S. £400.
Newcastle-upon-Tyne, University of Durham College of Medicine.—Lect. on Med. Jurisprudence. Sen. and Jun. Demonstrators of Anatomy. £450 and £350 respectively.
Preston Royal Infirmary.—Res. M.O. £180.
Queen Mary's Hospital, Stratford, E.—H.P.
Royal Free Hospital, Gray's Inn-road, W.C.—Obst. H.S. £50.
Salford Union Infirmary.—Res. Asst. M.O. £350.
Sheffield Royal Infirmary.—H.P. £150.
Southport General Infirmary.—Sen. H.S. and Jun. H.S. £250 and £175 respectively.
Stafford, Staffordshire General Infirmary.—H.S. £250.
Stockport General Infirmary.—Jun. Res. S. £200.
Sunderland Royal Infirmary (Children's Hospital).—Female Jun. Res. M.O. £150.
Surrey County Council.—Tuberc. M.O. £770.
Swansea General and Eye Hospital.—Jun. H.S. £200.
Swindon Borough.—M.O.H. and Med. Supt. of Isolation Hospital. £900.
Taunton and Somerset Hospital.—Sen. and Jun. H.S.'s. £200 and £150.
Tiverton Hospital, Devon.—H.S. £100.
University of London.—Prof. of Med. and Director of Med. Clin. £2000. Chair of Radiology. £1000.

Births, Marriages, and Deaths.

BIRTHS.

DE SMIDT.—On July 21st, at Blinco-grove, Cambridge, the wife of F. P. G. de Smidt, M.R.C.S., L.R.C.P., D.P.H., of a daughter.

MARRIAGES.

AITCHISON—FAIRBAIRN.—On July 27th, at New North United Free Church, Edinburgh, Captain R. Chalmers Aitchison, R.A.M.C., to Jessie Cunningham, daughter of the late Mr. and Mrs. David B. Fairbairn of Dunraven, Balerno, Midlothian.

DEATHS.

BATEMAN.—On August 2nd, suddenly, Francis John Harvey Bateman, J.P., M.A., M.D., of Heath End, Blackheath, aged 51.
EWART.—On August 1st, suddenly, at Eastney, Devonshire-place, Eastbourne, John Henry Ewart, M.R.C.S., L.R.C.P., aged 73.
MUNRO.—On July 18th, at Elmbank, Largs, Robert Munro, M.D., LL.D., in his 85th year.
NEEDHAM.—On August 2nd, at Clapham Park, Joseph Needham, M.B., C.M. Aberd., of Harley-street and Clapham Park, S.W.
VICKERS.—On August 1st, at Roseneath, Paignton, Charles William Vickers, M.R.C.S., L.R.C.P., D.P.H., in his 73rd year.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Communications, Letters, &c., to the Editor have been received from—

A.—Aberdeen, Medical Officer of Health of.
B.—Mr. J. Brittle, Derby; Dr. J. L. Brownlie, Manchester; Sir J. Barr, Liverpool; Capt. G. H. Barry, R.A.M.C., Alexandria; Col. R. J. Blackham, Bearsted; Dr. A. E. Boycott, Radlett.
C.—Cunard Steamship Co., Liverpool; Children's Country Holidays Fund, Lond.; Dr. C. Coombs, Bristol; Prof. A. R. Cushny, Edinburgh; Dr. P. J. Cammidge, Lond.
D.—Dr. J. S. Dunn, Swanage.
E.—Mr. J. Everidge, Lond.; Dr. A. Erdős, Oradea Mare.

Notes, Short Comments, and Answers to Correspondents.

THE ART OF HEALING.¹

BY PROFESSOR ARTHUR KEITH, M.D.

You have done me an honour by inviting me to come and speak to you, one which I should little deserve unless I can say something which will serve to quicken your interest in your daily work. Your business in life, as it is also mine, is to help in healing those who have been maimed by injury or disabled by the results of disease. If you were to say that I have no claim to be called a healer for the reason that I never see cases of sickness or attend upon them as physician or surgeon, I would reply that every man who teaches, and particularly any man who discovers, facts relating to the working of the human body is a healer, for we cannot hope to make a machine work rightly unless we know the nature and action of its parts. In this sense even an anatomist is a healer. In your case there can be no question; every day you have to apply treatment to men, women, or children for the relief of stiffness, paralysis, pain, or weakness, or one or other of the many disabilities to which the human body is so liable. You are healers, there can be no question of that. But whether it be a case of sprained ankle to which you are called upon to apply your art, or one of broken wrist, or to a man suffering from sciatica, a woman from rheumatic changes in the joints, a child suffering from the late effects of pleurisy, or a middle-aged spinster in the dire throes of facial neuralgia, your interest in your cases, your final success in dealing with them, and the ultimate health of your patient will depend upon your knowledge not of your own particular art, but of how far you have grasped the principles which underlie the Art of Healing. You will understand, then, why I have chosen this as a subject on which to address you, but you will also observe that in giving your secretary a title for my address I was careful to say nothing about principles, because when a Scotchman threatens to speak about principles everybody finds they have urgent business elsewhere. But having got you here I am to take a mean advantage and thrust my principles on you—the principles or laws on which the Art of Healing is based.

Decayed Teeth do not Heal.

There are no parts of the body which can better help us to understand the true nature of the art of healing than those structures with which we have been familiar from infancy upwards—our teeth. That most prevalent of all diseases, caries of the teeth, we all have had experience of at first hand. One morning we are surprised to find—or, if we are in the happier position of being able to afford regular visits to a dentist, our dentist is surprised to find—a hole or ulcer eating into a tooth without our being aware of the fact, there having been not the slightest warning or pain. Pain comes when the pulp cavity is reached—pain and plenty of it; but that is too late for Nature to step in and give us a preventive warning. If a sore or ulcer had formed on the cheek we should have been instantly aware of our danger and have been able to take measures for treatment. We should also know that, in most cases of ulcer or sore, repair will set in and heal the breach. But a hole or ulcer in a tooth will not heal, try how we will; it has no power of repair. The best a dentist can do for us is to clear out the dead tissue, introduce a stopping, and thus avert the disease. The most skilled dentist in the world cannot heal a tooth, cannot make the wall of the cavity produce fresh dentine and new enamel and thus restore the breach; his failure is not his fault, but that of Nature, because she has not given our teeth, for a reason I will explain presently, that virtue or healing power which she has most bountifully bestowed on all the other structures and tissues of our bodies. You will see the point I am trying to score—viz., that if Nature had not endowed our bodies with the power to heal, neither the surgeon, physician, nor masseuse could have done anything whatsoever for the cure of injury or of disease. They could have done no more—perhaps not so much—than the dentist can do for our teeth. They could only have stitched tears of the skin or stopped holes in the flesh. Conceive our condition if such had been the case: the hundreds of men who had broken bones in the accidents of civil life would be walking the streets in splints for the rest of their lives; every one of us would be covered with stitched cuts—often in want of renewal—or with holes which constantly wanted re-stopping, or with

ulcers ever weeping, or bruises unchangeably coloured as the rainbow. A modern city would be a warren of surgical out-patients, had Nature not endowed the rest of the body better than the teeth. Think of the condition of our soldiers at the end of a war if their bodies had forgotten how to heal! If we remember these things you will see that when we claim a cure we should not forget how much of our success we owe to the bounties of Dame Nature.

Healing Depends on Cells.

Why has Nature been so culpably negligent as to leave our teeth healingless? It is worth some trouble to look into this matter if only to learn how remarkably prudent she has been on our behalf in all her works. If our teeth had been provided with nerves as freely as our skin; then we should have had warning of the first onset of caries, and could have taken steps to remove the disease at its beginning. But then, what about cracking nuts and chewing roots and tough meat, as primitive man had to do? Eating would have been too painful a process to be indulged in. Nature did her best to secure attention to the teeth by awarding the most excruciating of pains to those who do neglect their teeth. Under the circumstances which conditioned her handiwork she could do no more. But lack of nerves does not explain why teeth have no power to heal, although I think that those parts of the body which are most liberally supplied with nerves of common sensation have a better power of healing than those which have a poor supply. The chief reason was that the substance of the teeth had to be made so hard and resistant that it was impossible to introduce into the enamel or dentine those soft living units which we speak of as cells. It is in these living cells that the power to heal lies; enamel cannot mend a breach in itself because it has got no cells; bone can, because everywhere it provides minute but comfortable nests or residences for the numerous living units scattered through its substance. If we would understand the art of healing, then we must know something of the living units in which the power to heal resides.

We must not think that every cell in the human body can play a part in the act of healing. A nerve cell, and it is also so with a cartilage cell, cannot even mend its own body, much less take a part in the healing of a breach or wound; if injured they die. The epithelial cells which cover the skin can, as you know, multiply, spread, and thus cover over any superficial breach of the body. The epithelium which lines the stomach, bowel, windpipe, and other canals and passages of the body have also this power. But the cells which have been furnished with the greatest degree of healing power are those of the white connective tissues—the tissues which bind the skin down to the underlying parts and which join together the various parts of the body. Let us suppose a muscle has been ruptured or torn, such as the biceps of the arm. Blood oozes into and fills the tear or breach in the muscle. Immediately messages go out, of kinds we do not yet know, and summon from the rest of the body millions of white blood corpuscles to the site of the injury—the workmen who have to clear away the debris caused by the accident. What interests us most, however, is the behaviour of the connective tissue cells lying in the walls of the breach. Up to the time of the accident they have been leading placid, passive lives, binding loosely together the fibres of the muscle without in any way interfering with their contractile duties. In ordinary circumstances they would have gone on performing this quiet duty all their days, just as their forefathers had done for endless generations before them. With the accident their disposition and mode of life change radically and suddenly. They take on, as it were, a fury of action, change their shape, begin to divide and breed, giving rise to broods of builders which are to mend the gap in the muscle. These builders are not poured out as an undisciplined mob; they proceed as orderly marshalled armies. As quickly as they grow out to fill the gap from the sides of the wound they are accompanied by sprouts from the neighbouring capillary vessels and are thus furnished with the means of sustenance. When the debris in the wound has been cleared away and the gap thus filled with a new army of connective tissue units, the units or soldiers begin to change from an active to a passive state; they shrink and form a cicatrix—a mere connective tissue cement. In this way Nature stitches the torn ends of the muscle together. We admit that the surgeon may expose the torn ends of the muscles, clear away the blood and damaged fragments, and stitch the torn ends together, but even when this is done Nature has still her operation to perform, for the only stitches which ultimately hold are those inserted by those extraordinary cobblers—the connective-tissue cells. What rouses these armies of menders to action we do not know. The power to heal is one of the marvels with which living tissues have been endowed. Unless it were so the surgeon would necessarily be a mere cobbler. All we do know is that these living units can do their work unaided by any

¹ Inaugural address at Summer Meeting of Incorporated Society of Trained Masseuses, June 29th, 1920.

human agency, but we also know we can hinder them as well as help them. Long ago Ambrose Paré put the matter in a nutshell when he said: "I dressed the wound; God healed it."

How to Aid the Cells Rightly.

The art of healing lies, then, not in knowing how we can heal the human body, but in knowing how we can help the living units of the body to perform this task for us. We have to study and know the habits and proclivities of these microscopic healing units of the body just as closely and well as we watch and note the ways and weaknesses of our best friends. We cannot watch those indispensable healing assistants too closely. John Hunter knew that. Every time he uncovered a wound and saw the red granulation tissue building up the gap in the flesh he studied it as a gardener does his most precious bud. He saw that the healing tissue must have quiet and comfort in which to do its work. Think for half a minute what progress you would make in mending a rent in your skirt if some restless terrier kept tugging at the hem. Your stitches would be ripped out almost as soon as you had tightened them. Think, then, of the uphill task that confronts the armies of cells which are trying to make good a tear or rupture in a muscle, if that muscle continues to be thrown into action. Nature has foreseen their difficulties and throws the muscle out of action. Hunter observed that if a muscle or tendon was ruptured the patient ceased to have the power to call it into action. At a later stage action and massage may become necessary, but of that we shall speak later on. It was long after Hunter's time that Pasteur and Lister discovered micro-organisms to be the chief enemies of the healing units. If such enemies can be excluded from the body the armies of healing tissue can proceed quietly about their work of mending; if they are not protected from these invaders they have to fight as well as build. It is like reaping a field of corn with most of the reapers serving as policemen. In this way surgeons greatly improved the art of healing by discovering simply why in some cases the real healers of the body were hindered in their work. Then other discoveries led on to further improvements in the art. It is a discovery of ancient times that the human body, after an attack of small-pox, was immune henceforth from this disease. Jenner found out that he could produce an immunity by vaccinating the body with the lymph of cow-pox. Then later we came to understand that the body of anyone attacked by a contagious or infectious disease was the scene of a widespread and terrific battle between invading hosts of micro-organisms and defensive mobile armies represented by the white corpuscles of the blood. At first the physician could do little more than look on and pray for the defenders to have the best of the fight, but by patient and continued observation he is learning how to strengthen the defenders by the use of vaccines, anti-toxins, and other methods of our modern serumtherapy. Here, again, the medical man is not really the healer; that power is inherent in the patient's blood and body; all he can do is to supply such conditions as are within his reach which will give victory to the defensive armies of the body. The best a physician can do is only to hold the lamp while Nature does the mending. But if he knows how to hold it rightly he may well make all the difference in the ultimate result, the difference between recovery and health.

We are but Nature's Assistants.

You will see that the conception I am thrusting home to you is that the power to heal or to regain health lies not in our hands or heads, but in the living flesh and blood of our patients' bodies. The most skilled of us—be we physicians, surgeons, obstetricians, or masseuses—are but Nature's assistants; she does the work, we only have to know how to wait upon her; to wait upon her judiciously is to practise the art of healing in its highest form. This, however, is not the opinion formed of us by the general public nor even by the educated public. Medical men, I fear, have occasionally conveyed the impression that they can heal or cure; one may hear the shallower man declare that he can cure this disease and that; that he saved this woman and rescued that child from death. As a matter of fact, he may have been an essential circumstance in the recovery, but if he is a wise man he claims no more; unless Nature had played her part he would have done his in vain. The impression has laid hold of the public that we can cure, and hence we are tempted to play the part assigned to us. The quack has seized upon this delusion of the public and fools it to the height of its bent by promising in the most unqualified terms to give an assured cure in exchange for a definite payment. They promise cures for cancer! Now that is one of the diseases which even Nature cannot remedy or cure, except on rare occasions. We do not know why she succeeds in these rare cases. Hence, ultimately, even cancer-curers have to own up that their nostrums are useless, because Nature does not support them. But in the great majority of diseases and disorders Nature herself is busy all the time trying

to get a cure; in these cases the quack has his opportunity and you may be sure he shares neither the profits nor the credit with Nature. Nature is also working for the physician, surgeon, and masseuse, and they, being conscious of that fact, try to discern not how far they cured the disease but how far the measures they have taken or the movements they have applied have really assisted Nature in securing a restoration to health. If you look at your daily work in this way every case becomes of interest to you. You must ask yourself—and only experience can teach you this—"if I do nothing to this case what will happen—how many days will Nature take to effect a cure; if I aid her in this way or in that by how many days shall I shorten her labour?" All the time you must remember that there is in your patient's body a mechanism of recovery, and whatever action you take or make must be such as helps that mechanism. The key to the art of healing is a knowledge of the reparative mechanisms of the body. That is why you must know the anatomy and physiology of every part, for how can you hope to restore action to muscles and joints unless you know how these act in health?

Rational Basis of Healing.

If in any way I were to undermine your confidence, if I were, in ever so slight a degree, to make you sceptical of the treatment you apply, I should do you an ill-service. Of the exact manner in which the patient's brain and his central nervous system can influence the tissues of his body and the healing power which is inherent in these tissues, we are largely ignorant at present. But we do know that it is an influence which can work on the reparative powers of the tissues—an influence which can work for good or for ill. We are all aware of that. Quacks ply their trade, trusting by a show of confidence to call that power into operation in their own favour. Christian Scientists, with more faith than knowledge, also rely on it and use it. With a backing from the natural powers of the flesh to heal, and the response with which the nervous system reacts to an implicit confidence, a faith-healer may pursue his or her way for a period with some appearance of success. But even in the short run Nature shows up their ignorance and the grossness of their pretence. It is otherwise with those who found the practice of their art on a rational basis. If you know how the movements you apply to your patients, be they passive or active, friction or stroking, effleurage or petrissage, are assisting the natural powers of the body to effect a cure, then you bring to bear on your patient not only the confidence of the faith-healer and the audacity of the quack, but the continued assurance which only rational knowledge can beget in a healer. You have, then, nothing to hide, nothing to explain away, and nothing to fear; all is as fair as the face of truth itself. The one condition is that there must be knowledge—knowledge of the powers of reparation inherent in bodies of man and beast alike.

EGYPTIAN VITAL STATISTICS, 1918.¹

EGYPT had a population estimated (on the basis of the 1917 Census) at 12,907,870 on July 1st, 1918, as compared with 12,760,229 in 1917. The birth-rate for the whole country was 39.0 per 1000, as compared with 40.3 in the previous year, and the death-rate was 39.7, compared with 29.5. The chief cities, Cairo and Alexandria, the Suez Canal (including Port Said and Ismailia), Damietta and Suez, form so many Governorates, this term being also applied to the sparsely populated Eastern and Western Deserts, the Oases, and the province or district of Sinai. The rest of the country is divided into Mudiriyehs (or provinces), of which there are six in Lower and eight in Upper Egypt. The birth-rate for the whole country was, as just mentioned, 39.0 per 1000. In Cairo, with a population of 763,320, the ratio was 36.7, compared with 41.3 in 1917; and in Alexandria, with 447,441 inhabitants, 36.5, compared with 40.2 in 1917. But in each of these large cities there was considerable variation, the Cairo births ranging from 27.0 per 1000 in the Esbekiya district and 29.1 in Helwan to 44.8 in Bulaq and 46.3 in Old Cairo; the proportion of births being, of course, in inverse ratio with the pecuniary prosperity (or social position) of the residents. Similarly, in Alexandria, the birth-rate varied between 24.7 in El Attarin and 43.7 in Mina al Basal. The town of Ismailia, situated on Lake Timsah, halfway between Port Said and Suez, with a population of 11,408, had the extraordinary birth-rate of 104.1 per 1000, an increase on that for 1917, which was 83.6. The death-rate was even more extraordinary, 738.6 per 1000 (compared with 130.4 in 1917): 7932 out of the total 8426 deaths were males. No explanation is given of this extreme fertility and fatality: presumably there was a large floating population in addition to those enumerated or estimated. For Egypt as a whole the death-rate was 39.7 per 1000, an immense increase on the ratio for 1917, which had been 29.5:

¹ Annual Return of Births, Deaths, and Infectious Diseases registered in Egypt during the Year 1918. Cairo: Government Press. 1920.

in the Mudiriyehs, or provincial Egypt, the ratios varied between 25.7 in Aswân and 41.9 in El Qalyubiya and in El Faiyum. In the Governorates, Cairo had a death-rate of 50.4 (compared with 35.8 in 1917), Alexandria had 43.3 (compared with 31.8), the Oases 80.8 (compared with 41.0), the province of Sinai 782.2 (compared with 56.3). Ismailia has been already referred to. Of the total death-rate (51.01 per 1000), more than one-third is due to three diseases. Gastro-enteritis of children caused 19,201 deaths, equivalent to 10.08 per 1000 (of the whole population); this prevailed throughout the year, was worst in June, July, and August (7517 deaths), and comparatively slight in January, February, and March (1585 deaths). Bronchitis, acute or chronic, caused 10,051 deaths (5.28 per 1000), of which 3454 occurred in November and December. Pneumonia and pleurisy caused 6256 deaths (3.21 per 1000), of which 3265 occurred in November and December. Probably deficient or unsuitable clothing was largely responsible for the prevalence in each of these three diseases. Happily there were only 23 deaths from hydrophobia; these were distributed throughout the year, except that there were no deaths in October and December; 12 occurred in July, August, and September.

THE ROYAL SURGICAL AID SOCIETY.

THIS Society, which was established in 1862, has done a large amount of good work in supplying poor persons with surgical appliances, thus rendering them more efficient members of the community, and in many cases helping the bread-winner to keep the family from being a burden on the State. It is now making an appeal for much-needed funds. To assist in this appeal a collecting-box in the form of a builder's brick, a specimen of which has been sent to us, is being sent out, and an attractive poster in connexion with it carries the message: "Be a brick and help build up the deformed, stricken, and maimed." The idea is an excellent one, for it forcibly reminds the giver that by subscribing to the Society, which is entirely undenominational, he is helping to reconstruct damaged elements of the industrial structure. The work of the Society is truly national and begins where that of the hospital leaves off. Some 500 appliances are supplied weekly. The appeal offices are at 26, Great Ormond-street, W.C.1, and the headquarters at Salisbury-square, E.C.

A FOOT ARCH SUPPORT.

WE have received from Messrs. Salmon Ody, Ltd., of New Oxford-street, London, W.C., an ingeniously constructed "arch support" for use in flat-foot and other cases where the instep requires support. Beneath a leather sock, shaped to the under part of the foot, is affixed a small mattress-like series of springs, the tension on which is modified according to need by turning a small screw-threaded rod. The apparatus is light and resilient in use.

CHILDREN'S COUNTRY HOLIDAYS FUND.

To the Editor of THE LANCET.

SIR,—It has been the practice of the Chairman of the London County Council at this period of the year to issue an appeal on behalf of the Children's Country Holidays Fund. For many years, by means of this Fund, a large number of the children attending the London elementary schools have been enabled to obtain a fortnight's holiday in the country, which has proved of substantial advantage to them from every point of view. This year the Fund has to face a considerable additional expenditure owing to the rise in prices. The charge for a child's board in the country has increased from 9s. to 12s. a week, whilst, owing to the difficulty of finding sufficient accommodation as a result of the housing problem, a few camps for elder boys are being organised, which will entail further expenditure. At the same time, unfortunately, subscriptions are considerably lower than last year.

May I appeal to all those who are shortly taking a holiday to remember the excellent work of this Fund in order that no children may fail to secure their holiday. Donations should be made payable to the Children's Country Holidays Fund, and should be sent direct to the Secretary at No. 18, Buckingham-street, W.C. 2.

I am, Sir, yours faithfully,

JOHN W. GILBERT,

July 30th, 1920. Chairman of the London County Council.

NECESSITOUS LADIES' HOLIDAY AND GENERAL FUND.

To the Editor of THE LANCET.

SIR,—In your kindness you have allowed me to appeal for years past for contributions towards the Necessitous Ladies' Holiday and General Fund, and I venture once again to ask the charity of your readers; for whose generosity in the past I could never be grateful enough. The poor ladies, unlike their sisters of the rougher classes, are suffering pitifully through the difficulty of obtaining work. I refer to

superannuated hospital nurses, governesses, literary ladies, musicians, painters, actresses and companions, many of whom, disqualified by age or infirmity to get engagements, are left behind in the city in the summer months exposed to the privations attendant on poverty.

The Fund also supplies food, medicine, and clothing, and comforts that are even more urgently needed than rest or change of air. Faced with the high cost of living on their tiny incomes, many are in daily anxiety.

I plead, then, for the old, the sick, and helpless. All contributions sent to the following address will be gratefully acknowledged and distributed.

I am, Sir, yours faithfully,

CONSTANCE BEERBOHM (Miss),

48, Upper Berkeley-street, London, W.1,

Treasurer.

August 3rd, 1920.

CHALYBEATE PUNCH: A QUAINT NORFOLK CUSTOM.

CHALYBEATE waters are unlikely ingredients for a bowl of punch, yet this is one of the principal features of a banquet recently revived by a West Norfolk Society known as the "Sons of Reffley." Reffley spring is about two miles from King's Lynn, in the midst of charming woodlands, and from it flows a chalybeate water reputed to possess medicinal qualities. It is strongly impregnated with iron, is of the consistency of ink, and in its raw state is not very pleasing to the taste. The society known as the "Sons of Reffley" is 200 years old, and at present contains about 30 members, who are called Knights of the Temple, their rites being performed in a quaint little temple close to the spring. At the annual banquet of the members, recently held for the first time since the war, the toasts were drunk in the famous "Reffley punch," a wonderful concoction of spirits and the chalybeate waters from this spring. This punch is prepared from an ancient recipe, the secret of which is known only to the successive presidents of the society, and the brew is prepared by the acting president in the morning before the members appear on the scene, and is imbibed from several quaint vessels of considerable intrinsic value belonging to the society. Each newly elected member has to drink a full mug of liquid from the spring, after which he is presented with a long churchwarden pipe. The present President of the "Sons of Reffley" is Sir Everard folkes, on whose property the spring is situated.

AN INDIAN MEMORIAL AT BRIGHTON.

THE Brighton Town Council on July 29th accepted the offer, made through Sir James R. Dunlop Smith, of a permanent memorial to commemorate the use of the Royal Pavilion as a hospital for Indian troops. It will take the form of a gateway at the southern entrance to the Pavilion, designed by Mr. Thomas Tyrwhitt, and intended to harmonise with the Oriental character of the buildings on the Pavilion estate. The money is provided by a number of Indian princes and gentlemen in recognition of the generous hospitality and attentions shown to their wounded compatriots by the people of Brighton. Sir Walter Lawrence, Sir John Otter, and Sir J. R. D. Smith were appointed, in conjunction with a local committee in Brighton, to decide on the form which the memorial should take.

PUFFS FROM PATIENTS.

LETTERS of thanks, real or fictitious, are part of the recognised outfit of the vendor of patent medicines. The regular practitioner of medicine has long ceased to make use of them in this country. In South Africa the practice seems still to persist. The following letter appeared in a recent issue of the *Natal Witness*:

SIR,—I am instructed by this branch of the British Medical Association to invite your attention to the fact that notices frequently appear in your valuable paper in which medical practitioners are thanked for services which they have rendered to patients. The Association desires that it should be known that the occurrence of the names of medical practitioners in such notices is not approved by it, and feels assured, when this is publicly known, that the practice will cease.

I am, Sir, yours faithfully,

(Signed)

ALEXANDER EDINGTON,
Hon. Secretary.

Maritzburg.

To this letter an editorial foot-note was added:—

We insert the above with pleasure. The Medical Association recognises, of course, that it is not possible for the press to actually refuse acceptance of such notices, but we have before endeavoured, at the request of the Association, to discourage a practice which is offensive to the majority of medical men.

Veritas.—As our correspondent continues to withhold his name and address we cannot reply to his questions, some of which merit attention. Incidentally he seems to mistake the scope of a medical journal, and to be entirely ignorant of the functions of the General Medical Council, where his previous anonymous communication was submitted.

The Croonian Lectures

ON THE

PSYCHOLOGY OF THE SPECIAL SENSES AND THEIR FUNCTIONAL DISORDERS.

Delivered before the Royal College of Physicians of London, June, 1920,

By ARTHUR F. HURST, M.A., M.D. OXON., F.R.C.P.,
PHYSICIAN AND NEUROLOGIST TO GUY'S HOSPITAL.

LECTURE IV.*—SEEING, LOOKING, AND HYSTERICAL BLINDNESS.

MR. PRESIDENT AND GENTLEMEN,—In the last lecture the psychology of hearing was discussed. It was shown how in order to hear it was necessary to listen, and that the process of listening involved some change at each synapsis in the auditory tract from the cochlea to the cerebral cortex, as a result of which resistance to auditory impulses was diminished.

In order to see it is necessary to look. Looking involves a process in the visual tracts strictly comparable to what occurs in the auditory tracts in listening. But in addition to this the action of a number of muscles is called into play, comparable to what I described in regard to listening, although the movements involved are more important and require much more delicate adjustment. Two distinct elements thus require consideration—the afferent, involving the visual tracts, and the efferent, involving certain motor tracts.

(a) The Afferent Element.

Inattention is rarely so profound in normal individuals that no visual impulses reach the brain at all, although complete absence of hearing not infrequently results from extreme inattention. It is common enough for visual impulses to be so blurred that a man, wrapped up in his own thoughts, does not see the approach of a friend, but he would always avoid obstacles if he were walking, and he would be aroused by the sudden approach of an object to his eyes; the latter would also give rise to the flinch reflex.

In the condition of stupor, which was not uncommon in soldiers who had been exposed to exceptionally terrifying ordeals, the mind appeared to be so completely absorbed with thoughts which had no connexion with the patient's present surroundings that he did not respond to any impulses from the outside world. He appeared to be blind, deaf, and anæsthetic; he gave no flinch (visual motor) or jump (auditory motor) reflex; cutaneous (tactile motor) reflexes were often, though not invariably, abolished; and the pupil contracted sluggishly or not at all on exposure to light. In spite of this he could feed himself if food was put in front of him, he did not stumble against obstructions if he were taken for a walk, and he occasionally showed a slight response to certain loud sounds, so that vision and hearing were clearly still possible, but it was difficult or impossible to induce the patient to look or listen even for a few seconds at a time. Exactly the same thing occurs in somnambulism. The doctor, seeing Lady Macbeth walking in her sleep, exclaimed, "You see, her eyes are open," and the gentleman replies, "Ay, but their sense is shut."

In the lecture on "Hearing, Listening, and Hysterical Deafness" it was explained how the idea of being unable to hear, suggested by temporary organic deafness, might give rise to a continued absence of listening and consequent deafness after the organic cause had disappeared. In the same way any condition which has led to complete though temporary blindness may suggest to the individual that he has lost his sight for ever; this is particularly likely to be the case if the temporary blindness is produced suddenly under terrifying conditions, as, for example, by the explosion of a powerful shell in the immediate neighbourhood. The slower onset of the temporary blindness in gassing, although the surrounding conditions might be equally terrifying, generally resulted in less profound hysterical blindness. When the suggestion that the sight is permanently lost has become thoroughly accepted the individual will cease to look. The visual tract is no longer prepared for sight by attention, and visual impulses consequently cease to pass up to the brain. In the act of looking the resistance at

each cell-station in the tract is diminished by some such process as a throwing out of dendrites or an alteration in the electro-chemical condition of the synapses. Consequently visual impulses not only give rise to no visual perception, but the flinch reflex and in the most severe cases even the pupil reflex to light disappear, as the resistance to the impulse even at the lowest synapses is too great to be overcome. More commonly the impulses produced by a very bright light can still break through the resistance, so that a sluggish reflex to light is obtainable, but the flinch reflex is still completely abolished.

When, as a result of psychotherapy, the patient realises that he can really see if he only chooses to look, he once more throws out the dendrites (or otherwise reduces the resistance) in the visual path and vision returns, the pupil and flinch reflexes becoming normal again at the same moment.

Injury or disease of the visual centre in the occipital cortex is the only organic condition leading to blindness in which the lower visual centres are unaffected. It might be expected that the flinch reflex would remain unaltered, corresponding with the persistence of the auditory motor reflex in decerebrate animals. This is not, however, the case, as Gordon Holmes,¹ in his unique experience of head injuries during the war, found that the flinch reflex was always lost in the blind fields of vision. This corresponds with the experimental observations of Sherrington, who found that the reflex was always abolished in decerebrate animals, even when the anterior corpora quadrigemina remained intact, although the auditory motor jump reflex remained unaffected. It is not at first clear why the latter should persist while the flinch reflex should disappear. But Sherrington points out that it is not every sound which can produce the auditory motor reflex in cerebrate animals, but that shrill peculiar sounds are the provocative ones, mere loudness appearing to be of no importance. As the effective sounds are neither injurious nor painful, they must have some other meaning, possibly connected with the sexual life of the animal. On the other hand, the retinal stimulus which gives rise to the flinch reflex may perhaps require remembered experience in order to be effective. Thus the reaction of blinking is anticipatory, the response being to threatened injury and not to actual injury. As memory and anticipation depend upon higher centres than the corpora quadrigemina and geniculata, the reflexes are abolished, both in animals and man, when the cortical centres are thrown out of action. The flinch reflex is thus a true visual reflex, being dependent, as von Monakow was the first to show, on visual perceptions.

It is clear from what has been said that in the absence of abnormality in the eyes there is no means of determining with certainty whether absolute blindness in the whole fields or in homonymous areas is organic or hysterical, as the flinch reflex is lost in both.

(b) The Efferent Element.

With the afferent element set in readiness visual impulses reach the occipital lobes, but nothing is seen clearly until the eyes are opened; the extrinsic muscles work in thorough coördination, so that the object to be looked at is brought into the centre of the field of vision of both eyes, and the ciliary muscles contract just sufficiently to bring it into correct focus. All these motor processes may be impaired as a result of suggestion, either alone or in addition to the afferent element already described. How this occurs can best be understood by a consideration of the hysterical disorders of vision which follow gassing.

Exposure to mustard-gas is followed in a few hours by pain in the eyes, which is increased by exposure to light. Conjunctivitis, blepharitis, and in rare cases keratitis, quickly develop. As long as pain and photophobia are present, the swollen lids remain closed. This is partly due to inactivity of the levator palpebræ superioris muscles, for the patient makes no effort to open his eyes, knowing that if he were to do so the exposure to light would cause pain. It is partly due to a protective reflex, which results in overaction of the orbicularis palpebrarum muscles, particularly if the patient does try to open his eyes. The object of this is to protect the eyes from being irritated by light; it is accompanied by reflex lacrymation, as a result of which irritating material is washed away. The inflammation gradually subsides, the reflex blepharospasm and lacrymation disappearing *pari passu*. At the same time the majority of patients realise that they can now open their eyes without hurting them, and in most cases they do so.

In individuals, however, who have become abnormally suggestible as a result of the stress and strain of active service, and in others who for any reason are particularly anxious about the condition of their eyes, the normal results of the conjunctivitis become perpetuated by auto-suggestion, to which may sometimes be added the hetero-suggestion

* Lectures I., II., and III. were published in THE LANCET of July 24th (p. 169) and 31st (p. 235), and August 7th (p. 285), respectively.

caused by injudicious treatment, such as the prolonged use of eye-shades and dark glasses, which give rise to an exaggerated fear in the patient's mind of the consequences of having been gassed. The voluntary inactivity of the levator palpebræ superioris becomes perpetuated as an involuntary inactivity, which may amount to actual paralysis, the condition being now one of hysterical ptosis. In rare cases the hysterical paralysis of the levator palpebræ may spread, hysterical paralysis of the whole of the face resulting (Case 8). A patient who finds himself unable to open his eyes by contracting his levator palpebræ muscles often attempts to compensate for this by contracting his frontalis muscles, and if the attempt meets with sufficient success to enable him to see through the chinks between his eyelids, he does this more or less constantly. The reflex blepharospasm is perpetuated as hysterical blepharospasm, which is generally most obvious when the patient attempts to open his eyes voluntarily, the eyes becoming more tightly closed than ever. The paralysis of the levator is thus accompanied by spasm of the orbicularis, just as hysterical paralysis of one group of muscles in a limb is often accompanied by hysterical spasm of the opposing group of muscles. The spasm often involves the neighbouring muscles or even all the muscles supplied by the facial nerve. Any attempt to pull the eyes open meets with great resistance, and a peculiar thrill is often felt owing to the irregular contraction of the orbicularis muscle. In some cases after it has become possible to open the eyes voluntarily the ptosis and blepharospasm manifest themselves intermittently in the form of attacks of blinking, especially on exposure to a bright light. Although hysterical ptosis and hysterical blepharospasm are generally present together, either may be present alone, and the proportion of one to the other may be different in the two eyes, as in Case 8.

In total blindness due to severe bilateral optic atrophy the eyes are kept open during the day and look straight forward, but they close during sleep. An uneducated man, however, if told to pretend that he is blind, generally closes his eyes, and when they are forced open or he is told to open them he at once turns them upwards in order to keep the pupils covered by the lids. Conversely, if he is for any reason unable to open his eyes he will very likely imagine that he is blind. Hysterical ptosis and blepharospasm are thus often accompanied by hysterical amblyopia, the patient having so convinced himself that he cannot see that he makes no attempt to look when his eyes are at last opened. When the lids are forced apart the eyes generally turn involuntarily upwards to protect them from the light. The pupils are consequently still hidden and vision is impossible. Even when the lids are sufficiently separated to expose the pupils the patient can only see indistinctly, and in rare cases he cannot see at all. The indistinct vision is due to a combination of hysterical paresis and spasm of accommodation. A man with normal vision relaxes his ciliary muscles to look at the distance and contracts them to look at a near object. A man who is convinced that he cannot see fails to regulate the activity of his ciliary muscles correctly when he opens his eyes. Instead of relaxing them when he wishes to look at a distant object he throws them into spasm, and he also fails to see near objects clearly, as he does not contract them to the correct extent. He has, in fact, lost control over accommodation, and, believing himself blind, looks at nothing.

The external ocular muscles may remain inactive as hysterical external ophthalmoplegia—a very rare condition, which I have, however, seen occasionally—or, much more frequently, certain muscles may be thrown into spasm in the attempt to bring them into action after long disuse, and hysterical strabismus results. Thus hysterical spasm of convergence is often seen when the eyelids are forced open, in addition to the contraction of the superior recti, which tends to keep the pupils hidden under the upper lids. In consequence of this abnormality of accommodation and convergence the patient sees nothing clearly, but he is not completely blind. Complete hysterical blindness, which is rare in cases of this kind, is due to the patient being so convinced that he cannot see that he does not use his visual centres at all; the psychology of this condition has already been described.

ILLUSTRATIVE CASES.

The following cases of hysterical disorders of vision have been selected from the large number I have seen as illustrating what I have already said concerning their pathogenesis. They also throw light on several questions connected with the ocular movements and reflexes, which have been the subject of controversy in the past. For the description of the majority of cases I am indebted to the medical officers who worked with me at the Seale Hayne Hospital, especially Captain A. Wilson Gill, Captain C. H. Ripman and Captain R. G. Gordon.

In the first case the blindness was the most nearly absolute I have seen result from hysteria. It is of exceptional interest, as it is also the only case in which the reflex contraction of the pupils to light was abolished. So far as I am aware no similar case has hitherto been described.

CASE 1. Total blindness with loss of pupil reflexes following shell concussion; hysterical nature proved by rapid cure by psychotherapy after persisting for four years.—Pnr., aged 41, went to France in September, 1914. After six weeks' fighting he was stunned as the result of the explosion of a shell in his immediate vicinity. In the evening he noticed he could not see clearly and attributed this to the shock of the explosion. He at once feared he would lose his sight; his eyelids began to droop and he had difficulty in focussing near objects. He was sent to England where the use of eye drops and dark glasses confirmed his fears, and in a short time he became totally blind. Early in 1915 he was discharged as permanently unfit, receiving a full pension for total blindness. He was examined every six months after this, but no treatment was given. In November, 1918, he was seen by Mr. J. R. Rolston, of Plymouth, who recognised the condition as hysterical and advised his transfer to Seale Hayne Hospital, where he was admitted on Nov. 13th, 1918. He presented the picture of the typical blind beggar of the street. Unshaven, unkempt, and dirty, and wearing a pair of dark glasses, he came supported by his wife, while in his hand he carried a thick stick to help him guide himself. Whilst wearing the glasses he kept his eyes open, but could see nothing; when they were removed he was unable to raise the lids owing to severe blepharospasm, except in a darkened room.

Treatment was commenced the same evening, and in a short time the blepharospasm was overcome and the patient opened his eyes, but he was still totally blind. The pupils were then found to be widely dilated, with no trace of reaction to light. The finch reflex was completely absent in both eyes. Ophthalmoscopic examination showed nothing abnormal, and a definite diagnosis of hysterical blindness was made. Explanation as to the nature of his condition and encouragement to use his eyes rapidly led to partial restoration of vision, but at the end of two hours he still stumbled over objects placed in his path. After a rest of an hour treatment was continued and further slight improvement occurred. In attempting to focus his eyes he made strong contractions of the muscles of the neck similar to those seen in the spastic variety of hysterical aphonia when the patient attempts to speak.

The next morning he was taken out of doors, and distant objects were soon recognised. An endeavour was then made to teach him to focus his eyes on nearer objects, and by the evening he could read 6/24 at 20 feet. The excessive contractions of the neck muscles continued, however, but by encouraging him to relax they gradually disappeared and vision steadily improved. He was still inclined to stumble over objects placed in his path, but this was merely due to inattention. On Nov. 25th he could read with each eye in turn 6/12 at 20 feet and could spell words printed in small type, but as he was almost completely illiterate he could not pronounce them. The finch reflex and the normal pupillary reactions to light had returned the first evening.

The patient was also completely deaf in the left ear on admission; he was given instruction in listening, and at the end of a week he could hear normally. When seen four months later, in February, 1919, he was at work as a watchmaker and gramophone repairer.

Whilst a man is still dazed as a result of being blown up by a high-explosive shell he pays no attention to any external stimuli, and may be regarded as psychically blind, deaf, and anaesthetic. His sight, hearing, and cutaneous sensibility generally return as he regains consciousness, but if there is anything which draws his attention to his eyes the blindness may persist as a result of auto-suggestion. The following is one of seven cases seen with Major A. W. Ormond,⁴ in which sand was blown into the men's eyes from the sand-bags of the parapet on which the shell exploded. The irritation it caused drew their attention to their eyes and resulted in blepharospasm and amblyopia, which persisted long after every sign of conjunctivitis had disappeared. These early cases were the only ones in which hypnotism was used.

CASE 2. Hysterical blindness following exposure to a shell explosion cured by hypnotism.—The patient, aged 22, was looking over a parapet at Gallipoli on July 18th, 1915, when a shell struck the sand-bags in front of him. He remembers the sand being thrown up into his eyes, after which he fell back and knocked his head. He was unconscious for 24 hours. His first impression on regaining consciousness was extreme irritation in his eyes. He tried to open them, but found he could not do so. His mind thus became concentrated on his eyes, and owing to the confusion which is common among the uneducated between inability to open the eyes and blindness, he became absorbed with the idea that he was blind and that he would never be able to open his eyes or see again. The impairment of other functions, which was doubtless present at first, remained unnoticed in this greater trouble, except for some loss of hearing, which quickly disappeared. The condition of his eyes had not altered when I first saw him on Sept. 17th, 1915. He was quite blind, and there was a constant flicker of his eyelids, which were kept almost closed. On forcibly opening his eyes they were found to be turned so far upwards that it was difficult to see even the iris. A few fragments of sand were still embedded in the conjunctiva but not in the cornea; there was no inflammation. The inability to open the eyes and the idea of blindness were thus perpetuated by auto-suggestion, and persisted long after the inflammation caused by the dust had disappeared.

The patient was easily hypnotised, and whilst asleep he was told that he would be able to see when he woke up. The moment he awoke the suggestion was repeated very forcibly, and his eyes were held open. He cried out that he could see, tears ran down his cheeks, and he fell on his knees in gratitude, as he had thought that he was permanently blind, and believed that his sight had been restored by a miracle. When seen again on Sept. 20th the external appearance of his eyes was normal, and he said that he was able to see as well as he had ever done. There was some opacity of the vitreous of the left eye, which was doubtless a result of injury at the time of the explosion. There had been no return of symptoms, and the patient was well in every way when I last saw him on Sept. 30th. His vision was 6/6 in the right eye and 6/36 in the left.

In the next case the blindness was so typical of what would be expected to follow a wound in the occipital region that no doubt was felt as to its organic nature. The sequel, however, proved that it was due to the perpetuation by auto-suggestion of the organic blindness, which had been caused by concussion rather than destruction of the visual centres in the occipital cortex. The patient realising that he was blind in certain directions ceased to look in these directions: the dendrites were perhaps retracted at the synapses in the affected tracts and the flinch reflex consequently disappeared. When at last the cedema and other changes produced by the initial concussion of the occipital cortex had disappeared and vision was again possible, the patient had become so accustomed not to look in the blind fields that no spontaneous improvement occurred.

CASE 3. *Hysterical blindness in three quadrants of the visual field, following organic blindness caused by a wound in the occipital region and associated with hysterical deafness.*—Pte. W., aged 22, was wounded over the lower part of the right occipital region near the middle line on June 7th, 1917. He was unconscious for five days and was then trephined. On admission to Netley, on July 6th, 1917, he was completely deaf in both ears, but as the vestibular reactions on rotation were normal the deafness was regarded as hysterical. It was noticed that he had difficulty in seeing and that he held anything he wished to read low down on the right side, although he volunteered no complaint about this, and only spoke about his deafness. On further examination it was found that he was totally blind except in the right lower quadrant of the field of vision of both eyes, the blindness being what might be expected to result from the wound which had probably involved the whole of the visual centre on the right side, but only the lower part of the calcarine cortex on the left. An attempt was made at the end of August to cure the hysterical deafness by a pseudo-operation, the patient being told that a cut behind his ear would certainly restore his hearing. Nothing was said to him about his blindness, which was regarded as organic. The "operation" resulted in immediate improvement in his hearing, as it at once became possible to carry on a conversation with him by shouting. Quite unexpectedly it was found that his vision was now absolutely normal, the blindness having been cured by the suggestive effect of the "operation."

I shall now describe the different varieties of hysterical visual disturbances, which were such a frequent result of gassing. The first case is an example of the common form in which both eyes were equally affected; the patient was unable to open his eyes owing to a combination of hysterical ptosis and blepharospasm, and when the eyes were opened he only saw very indistinctly.

CASE 4.—*Hysterical blepharospasm, ptosis, and amblyopia of four months' duration.*—Gnr. K., aged 33, had been in France seven months, and for most of the time was on duty behind the firing line, because his nerves were not equal to life at the front. In December, 1917, he was blown up, and was then very shaky and frightened. He was gassed on April 9th, 1918. Next morning he was unable to open his eyes. When admitted to Seale Hayne Hospital, under Captain C. H. Ripman, in August, 1918, he could only see indistinctly through the narrow slit which he could produce by a great effort between his eyelids by strong contraction of his frontalis muscles, and he used his hands to steer himself. A thrill caused by contraction of the orbicularis muscles was distinctly felt in the lids when an attempt was made to force them open.

The orbicularis spasm relaxed and he recovered the power of his levator palpebræ muscles in five minutes as a result of persuasion, and he was then quickly trained to see perfectly well. For a time he was inclined to blink and to let the upper eyelids droop a little; this was due to persistence of slight ptosis, caused by hysterical paresis of the levator palpebræ muscles, and not to spasm of the orbicularis, and in order to counteract the ptosis he continued to wrinkle his forehead. He made a slow but steady recovery from this habit, and was discharged from hospital completely cured a few weeks later.

In Cases 5 and 6 one eye was more severely affected than the other. There must always be some explanation for an asymmetrical condition resulting from a cause which would be expected to act symmetrically. In hysteria the explanation is always a psychical one. In the cases in which visual symptoms were more marked in one eye than the other after gassing it was found that the patient had for some reason been anxious

about the vision of the former, which may, in fact, have been less acute than the other on account of an error of refraction.

CASE 5. *Hysterical ptosis with unilateral blepharospasm and amblyopia cured in an hour.*—Cpl. B. was gassed in France in June, 1918. This resulted in severe conjunctivitis. As he could not open his eyes he was afraid he might go blind. He was particularly anxious about his left eye, as it had always been weak and subject to inflammation and styes. In order to protect the eyes when painful he had kept the lids closed, and when the inflammation had subsided he found he was unable to open them. If the left lid was raised he experienced great discomfort and everything seemed blurred. The right eye was not painful and he could see clearly with it, but in order to do so he had to raise the lid by contracting the frontalis muscle, as he could not use his levator palpebræ. He was admitted to Seale Hayne Hospital under Captain R. G. Gordon on Oct. 23rd, and an hour's persuasion was sufficient to induce him to use the proper muscles and to relax the spasm of the right frontalis, but the spasm tended to relapse for a few days unless he paid special attention to it. The vision of the left eye quickly returned with re-education of accommodation.

Cases of Ptosis.

The next case is of interest in connexion with the part taken by the frontalis muscle in ptosis. It is generally taught that hysterical ptosis can be distinguished from ptosis due to organic disease by the fact that the latter is accompanied by compensatory overaction of the frontalis muscle in the effort to keep the eye open, whereas this never occurs in the former condition. Thus Purves Stewart⁵ and Oppenheim⁶ make the distinction without mentioning the possibility of exceptions. In the following case, however (and also in Cases 5, 7, and 8), there was as marked compensatory overaction of the frontalis as occurs in any case of organic paralysis. The complete recovery after a few minutes' treatment by psychotherapy, although the ptosis had persisted without alteration for a considerable time, confirmed the diagnosis of hysteria. It is not surprising that the belief that compensatory action of the frontalis only occurs in organic ptosis should prove erroneous, as it would seem very natural that a man who was unable to open his eyes by contracting the levator palpebræ superioris should attempt to do so with his frontalis muscle, and it is obvious that in organic ptosis the overaction of the frontalis is purely voluntary. As the exact manner in which hysterical ptosis manifests itself depends simply on the patient's own conception of a drooping eyelid, it would be astonishing if the frontalis did not always contract, and in all the cases of pure hysterical ptosis which I have examined the frontalis did, in fact, contract. It is clear, therefore, that the supposed distinction between organic and hysterical ptosis, which has been copied from one book to another, cannot be regarded as of any value in diagnosis.

CASE 6. *Hysterical blepharospasm, ptosis associated with overaction of the frontalis, and amblyopia following gassing and cured by psychotherapy.*—Corporal H., aged 22, was gassed on May 20th, 1918. He was admitted to hospital the same day with conjunctivitis, his eyes being tightly closed. Thirteen days later he was able to open his left eye, but the right one still remained closed, and he thought he was blind in that eye. Early in June he was transferred to a military hospital in England, where he remained for a fortnight. He was then sent to a V.A.D. hospital and treated with electricity and daily eye-baths with no improvement. He was admitted to Seale Hayne Hospital on Oct. 22nd, under Captain S. H. Wilkinson, with the right eye tightly closed owing to unopposed spasm of the orbicularis, but the left eye was kept partially open as a result of continuous contraction of the frontalis muscle. Vision was so indistinct that he could only see with difficulty, and he was quite unable to read. No conjunctivitis was present, but at the corner of the right eye there was a scar on the skin about the size of a two-shilling piece; this was caused by a nevus having been burnt off when he was a child. He had always believed that this had impaired the sight of the right eye. After being in France for a few months he noticed that the sight of the right eye was becoming more "blurred," and when he was gassed he was at once terrified that he would be completely blinded in this eye. He was treated by persuasion, and in half an hour the orbicularis spasm of the right side and the ptosis of the left were overcome, and he was then quickly trained to focus his eyes, so that his vision became quite normal except for some myopia of the right eye, which had always been present and was doubtless the real cause of this eye being the weaker one.

In the following case the ptosis which was present on one side spread so as to produce complete facial paralysis, which was remarkable in that the only unparalysed muscle was the frontalis, which attempted to counteract the paralysis of the levator palpebræ superioris. The platysma was also involved contrary to what would be expected from Babinski's teaching, as he regarded paralysis of this muscle in facial paralysis

as a definite sign that the condition is organic. This is not, however, the only case I have seen in which Babinski's platysma sign has proved to be misleading. Whilst the ptosis spread to produce facial paralysis, the blepharospasm of the affected side spread to produce facial spasm.

CASE 7. Hysterical left facial paralysis and ptosis, right facial spasm, paralysis of right arm and both legs, aphonia, dysarthria, and amblyopia following gassing.—Lieut. B., aged 28, was gassed on April 24th, 1918. He remained quite blind and very hoarse for about six days. When sent to England on May 3rd he could see a little and could talk fairly well. On reaching the hospital, however, he could hardly open his eyes and was very breathless. The base of the right lung was dull and crepitations were present; his sputum was blood-stained. He improved, but the left side of his face and his right arm and leg became paralysed during the next few days. He gradually lost the power of speech; he could not phonate at all and could only make unintelligible, whispering sounds. He was unable to open his mouth, and could thus only take fluid food. A few days later the left leg became swollen and a tender spot developed over the femoral vein, apparently due to thrombosis; the other leg soon became affected in the same way to a less extent, but rapid improvement occurred, so that the last trace of swelling had disappeared by June 10th.

When I first saw him on June 16th his eyes were closed and there was a constant spasm of the whole of the right side of the face, especially involving the orbicularis palpebrarum and levator anguli oris. The left side of the face, including the platysma, was completely paralysed except for the frontalis, which contracted with excessive vigour in the patient's efforts to overcome the ptosis, which was present on both sides in addition to the spasm on the right side, and this prevented him from seeing unless he held his left eye open. When the upper lid was held open and the right lids pulled apart it was found that there was a marked squint due to spasm of the internal recti. The masseters were tightly contracted, so that he could not open his mouth. Spasm was also present in the left side of the tongue, so that when later he was able to open his mouth and put out his tongue it went to the left. The right arm and leg were completely paralysed, and he was only able to move the left leg with difficulty. With simple persuasion and re-education in breathing he quickly learnt to phonate, and then gradually learnt to articulate clearly. The ptosis of the left eye was overcome by persuasion without difficulty. The spasm of the muscles of the right side of the face slowly improved with massage and stretching the muscles by pulling the eyelids apart and pulling down the upper lip, which was gripped with one finger inside the mouth and the other outside. When at last he was able to open the right eye it was found that he could hardly see with it, but with simple explanation and persuasion the amblyopia disappeared. The severe internal strabismus, which was present when both eyes were open, gradually disappeared as he became accustomed to using his eyes. With some difficulty he was taught to balance himself while standing, after which he quickly learnt to walk. He was treated at intervals from 10 A.M. until 6.30 P.M., by which time he could walk normally. His right arm had now recovered without special treatment, and for the first time since the onset of symptoms he was able to write. He could talk with a normal voice, but in a somewhat laboured manner. The paralysis of the left side of the face and the ptosis had completely disappeared, but there was still some slight spasm of the right side, although he could now open the eye and see quite clearly, and there was no squint.

It is difficult to account for the extraordinary variety of hysterical symptoms which developed in this officer, but from his history it is apparent that whilst some were produced by auto-suggestion others probably developed as a result of unconscious suggestion on the part of those who examined him. He must have been constitutionally suggestible, and the stress and strain of active service, and particularly a heavy bombardment with gas shells every night before he was finally gassed, must have rendered him still more suggestible. As was so often the case in the war, most of the hysterical symptoms developed gradually during the stages of his journey to the base and thence to England, whilst some only appeared after his arrival at an English hospital. The reflex protective aphonia which resulted from the irritating action of the gas on his throat was perpetuated by auto-suggestion. The pulmonary thrombosis, which appears to have developed on his way to England, led to further respiratory symptoms, which were exaggerated and perpetuated by auto-suggestion, so that to the original aphonia was added a severe dysarthria. Frequent examinations of his nervous system must have unconsciously given rise to the idea in his mind of the paralyses and spasms affecting various parts of his body, and the original protective closure of his eyes was perpetuated as blepharospasm on the right side and ptosis on the left, the former spreading so as to involve the whole of the side of the face and the latter becoming complicated by left-sided facial paralysis. The closure of the eyes led by auto-suggestion to the idea of blindness.

Apart from an attack of phlebitis, he remained fit except for a periodic left-sided headache, which made him wonder whether he was not still suffering from

organic brain disease, until February, 1920, when he intervened in a domestic dispute between his sister and her husband, immediately after which several of his original symptoms recurred. He was readmitted into hospital under Captain Wilkinson on April 21st, 1920, with blepharospasm of the right eye, flaccid paralysis of the right arm, spastic paralysis of the right leg, and great difficulty in articulation. It was explained to him that owing to the doubt in his mind as to the continued existence of brain disease because of the pain in the left side of his head, and knowing, as he did, that the left side controlled the right side of the body, his mind was just waiting for an excuse to produce the old symptoms again, and this excuse was afforded by the excitement of his intervention in the family squabble. Explanation was followed by persuasion and re-education, and in the course of an hour all the symptoms had disappeared.

Hysterical Blindness in a One-eyed Man.

In the following case hysterical blindness occurred in a one-eyed man. The exciting cause would probably have been insufficient to have affected him had he not been living in perpetual fear that something might deprive him of the sight of his remaining eye.

CASE 8. Partial hysterical blindness following shell concussion in a one-eyed man.—Sapper C., aged 28, lost his left eye in 1914 as the result of a shot-gun accident. When he enlisted in 1917 the vision of his right eye was 6/6. He went to France in May, 1918, to work on the railway. In June, 1918, an aeroplane dropped a bomb about 25 yards away, but did not hit him. The force of the explosion, however, was sufficient to dislodge his glass eye from its socket, and simultaneously his right eye became completely blind. The total blindness only lasted for a few days, but very defective vision persisted. He also noticed that erect objects such as telegraph poles appeared to be distorted. He passed through several hospitals where the hysterical nature of the condition was recognised; he was still uncured when he was admitted to Seale Hayne Hospital under Captain Gill on Oct. 25th, 1918.

On examination there were no signs of disease in the eye. The pupil was of small size and reacted briskly to light, but on attempting to focus an object he contracted the muscles of his neck, rotating his head to the right side, and alternate slight variations in the size of the pupil were evident. When he tried to read he held the book low down and either to the left or right side. At a distance of two feet from the eye he could see objects distinctly, but anything nearer or beyond this limit was blurred and indefinite. The finch reflex was completely absent. His mental attitude was one of great anxiety, and he was considerably depressed at the possibility of complete blindness.

He admitted that he went to France in considerable fear lest anything should happen to cause the loss of his one eye. The shock of the bomb explosion was sufficient to drive out his artificial eye, and this immediately suggested to him some damage to the other eye. Treatment directed towards relieving the patient's fears and encouraging him to relax his ciliary muscle was speedily followed by complete recovery with return of the finch reflex. Inequality of the pull of the ciliary muscle on the lens accounted for the distortion of upright images. On discharge from the hospital some weeks later his vision was 6/6.

In the next case the primary irritation of the eyes was caused by a sandstorm. It is of interest as showing two forms of hysterical blindness in one individual; in the right eye the motor element was alone affected, but in the left eye, which was more severely damaged in the sandstorm, so that the suggestion of blindness must have been stronger in connexion with this eye, severe psychical blindness was present as well. The latter was almost as complete as the blindness of both eyes in Case 1, and corresponding with this the pupil on this side was dilated compared with the other, and only responded very sluggishly to light.

CASE 9.—Hysterical blindness following sandstorm; 26 months' duration; cured by psychotherapy.—Pte. F., aged 52, was caught in a sandstorm in December, 1916, without any protection for his eyes. He developed intense conjunctivitis and keratitis with severe pain and photophobia, and was unable to open his eyes. Despite the fact that the inflammation and pain gradually disappeared, he was still unable to open his eyes when he was sent home from Egypt. In March, 1917, no improvement having occurred, he was discharged from the army as permanently unfit with a disability of 100 per cent.

On Feb. 10th, 1919, he was admitted to Seale Hayne Hospital under Captain Gill. He wore a pair of dark glasses, on removal of which he was found to have severe bilateral blepharospasm. With explanation and persuasion the spasm of the orbicularis muscles and the spasm of convergence which was also present were speedily overcome. It was then found that the left eye was completely blind, so that the patient could not distinguish light from darkness, and could face the sun without blinking. The vision of the right eye was very defective, but he could pick out large objects and name some of them correctly. The pupils were unequal in size, the left being slightly the larger. Reaction to light was normal in the right side, but very sluggish in the left. Reaction to accommodation was irregular, but was sometimes brisk in both eyes. The blink reflex was present on the right side, but was completely absent on the left. Ophthalmoscopic examination showed that the

retinae were normal. There was no conjunctivitis, but slight keratitis was present in both eyes, being most marked in the left. Captain R. Jaques, who examined him for us, reported: "I can find nothing to account for the defect in vision. The corneal nebulae are not sufficient for this."

Complete recovery followed psychotherapy; the pupils became equal in size and reacted normally, and a brisk finch reflex was present on both sides. In the case of the right eye all that was required was to teach the man to regulate the action of the ciliary muscle, relaxing it for distant objects and contracting it for near objects. In the case of the left eye it was necessary first of all to convince the man that he would be cured, and then to encourage him to look with it.

There has been much discussion in the past as to whether homonymous hemianopia can ever be hysterical. Several cases, however, have been described. The following case is of interest, as hemianopia of one eye was associated with partial blindness of the whole field of the other eye.

CASE 10.—*Hysterical blindness of one eye and hemianopia of the other cured by psychotherapy.*—Bdr. U., aged 25, developed severe conjunctivitis as the result of a bombardment with mustard-gas shells on March 21st, 1918. After three weeks' treatment he was able to open his eyes, but found that he was almost completely blind in the left eye, being able to see only a white mist, while with the right eye he could see imperfectly. He was admitted to Seale Hayne Hospital under Captain Gill on Nov. 5th, 1918. The eye specialist's report accompanying him stated: "Left eye completely blind, right eye 6/24." On admission there was no conjunctivitis, and no sign of corneal scarring. The pupils were equal in size and reacted sluggishly to light and accommodation. The left eye was completely blind and the finch reflex was absent. With the right eye he could see distant objects clearly. On attempting to read with the right eye he held the book slightly to the right side, so that the light from the book fell on the nasal half of the right retina, the temporal half of which appeared to be blind. The finch reflex was abolished except when the direction of the blow was towards the nasal half of the right retina. Peripheral vision as tested with the moving finger was extremely defective in the right eye. Ophthalmoscopic examination showed the presence of a tiny foreign body embedded in the lens of the left eye, but no other organic changes were apparent. As the result of psychotherapy, complete recovery resulted in each eye, both for near and distant objects, and the finch reflex was completely restored.

The presence of a small foreign body in the left lens, which had apparently been driven in some time before, had given rise to no visual trouble at the time beyond making the patient aware that the vision of the left eye was less good than that of the right. This no doubt accounted for the more complete hysterical loss of vision in this eye after the gassing. Believing that he was completely blind in the left eye, he appears to have subconsciously come to the conclusion that he would necessarily be blind to everything on his left side, and in this way the loss of the nasal half of the field of vision of his right eye was suggested.

The next three cases have no connexion with the war, although two of them occurred in soldiers. For different reasons in each case the patient had unconsciously taught himself to ignore the retinal impressions produced by one eye to such an extent that it had become blind, the condition being exactly analogous to the hysterical blindness already described. In the first case the patient taught himself to see once more with the blind eye when he began to lose the sight of the other as a result of optic atrophy. In the other two cases vision was restored by psychotherapy.

CASE 11. *Hysterical blindness of left eye; recovery of left eye following loss of sight of right eye caused by syphilitic optic atrophy.*—John P., aged 40, received a blow over the left eye in 1915; he could not open it, but on raising the lid he found he was blind. During the next eight months he regained the power of the levator palpebrae superioris, but he could still only see with his right eye. He was able to carry on with his occupation as a brass-worker until August, 1919, when he found that vision with his right eye was becoming blurred by an orange-coloured mist. He now covered his right eye with a shade, and quickly taught himself to see almost perfectly with his left eye, which he had thought was blind. When he came under observation in October, 1919, it was found that the recent loss of vision in his right eye was due to advanced optic atrophy, and the slight deficiency in the left eye was due to slight changes of the same nature. The right pupil reacted to accommodation but not to light, the left pupil responded to both. There were no other physical signs of disease. The Wassermann reaction of both blood and cerebro-spinal fluid was positive, and 54 lymphocytes per c.mm. were found in the latter, together with slight excess of globulin. The optic atrophy was obviously of syphilitic origin, but there were no signs either of general paralysis or tabes. Antisyphilitic treatment was given, but no change in vision resulted.

The blindness of the left eye following the blow was suggested by the pain and bruising which prevented him from raising the lid. Four years later loss of sight in his other eye prompted him to try to see with his left eye, and to his surprise he found he could soon see fairly well. In order to abolish the blurred image produced by the right eye he covered this up. The slight deficiency in vision which persisted in the previously blind eye was not hysterical like the original total blindness, but was caused by a slight degree of optic atrophy.

In the next case the patient had a congenital defect of one eye which led to deficient vision. He had learnt to neglect what he saw with this eye, but still retained

some vision in it, when at the age of 15 for no obvious reason he became almost totally blind in it. The blindness was suggested by the defective vision caused by the congenital abnormality and was cured by psychotherapy; it could thus be correctly regarded as hysterical.

CASE 12.—*Combined hysterical and organic blindness in the right eye; hysterical element cured by psychotherapy after four years.*—Pte. M., aged 19, had never seen as clearly with his right eye as with the left. In 1914, while working as a clerk, he noticed that the right eye was becoming blind, and in February, 1918, when he enlisted, he could only just distinguish light from dark with it. Captain Jaques found a persistent hyaloid artery passing from a posterior polar cataract to the optic disc. With very little persuasion he was taught to use the right eye again so well that he could read without difficulty. The pupil reactions were present in each eye, but the finch reflex was totally abolished until vision was restored, when it became quite normal.

A severe squint dating from childhood in a man of 25 would not at first be regarded as likely to be hysterical. But in the following case not only the squint but also the associated loss of vision in the affected eye appear to have been of this nature. It is well known that when diplopia develops in adults they unconsciously train themselves to ignore one image; the same thing occurs in children who develop a permanent squint. The eye which ceases to be used in this way becomes more or less completely blind. After it has persisted for several years it is generally held that the blindness is permanent, and that while an operation may be performed to bring the eyeball into a central position, yet no improvement in vision is likely to occur. Moreover, in the event of an injury occurring to the sound eye sufficient to cause blindness, the previously squinting eye is generally said to be only capable of recovery if the squint has not been in existence for more than six or seven years.

CASE 13. *Hysterical blindness in a squinting eye; improved by psychotherapy after persisting for 20 years.*—Rifeman B., aged 25, at the age of 6 was frightened by a performing bear, and his mother states that he has squinted inwards with the left eye ever since, although she is confident that there was no squint prior to this event. On admission to Seale Hayne Hospital under Captain Gill on July 19th, 1918, with hysterical paralysis of the right hand, which was cured the following day, the left squinting eye was found to be almost completely blind. There was no paralysis of any of the ocular muscles. Captain Jaques found +3 diopters of hypermetropia in each eye.

There is no adequate explanation why squinting should result from an error of refraction which is equal in the two eyes. It seemed probable, therefore, that the squint was really a result of the fright caused by the bear. This might have caused a hysterical convulsive seizure, associated with squinting, as is so often the case in the convulsions of children. It was assumed that the squint had become perpetuated as a hysterical symptom, and an attempt was therefore made to treat both the squint and the blindness by psychotherapy. The patient was quickly taught to keep the two eyes nearly parallel. He was then shown how to use his left eye, and at intervals the right eye was kept covered in order that the other should be in constant activity. We did not, however, succeed in curing the squint, although the patient could overcome it whenever he tried, and vision had so far recovered in the blind eye that the patient could read large type.

The disturbances in vision so far described were independent symptoms and filled the whole clinical picture. Hysterical blindness may also occur in one eye associated with paralysis of the same side as in the following case, the graphic description of which we owe to Carré de Montgeron.

Hysterical hemiplegia and hemianesthesia with total blindness, immobility, anaesthesia, and loss of conjunctival and corneal reflexes of the corresponding eye.—On Dec. 24th, 1717, Marie-Jeanne, the 27-year-old wife of François Stupart, of Eprenai, was seized with "apoplexy." After three days of fighting between life and death the attack left her with paralysis and loss of sensation affecting the whole of the left side. "Of all the parts involved in this sad malady," wrote Montgeron, "the eye was the most seriously affected; the roots of the optic nerve of the left side were entirely enveloped in the obstruction of the brain; and this nerve is the immediate organ of vision, the obstruction which deprived it of all action rendered it absolutely incapable of perceiving light. At the same time the other nerves which serve for the movements and procure the sensibility both of the globe and the eyelids were equally completely obstructed; thus the eye and the lids lost all sensation and remained immobile. . . . The insensibility was so great that one could easily put one's finger between the lids and touch the eyeball without causing any movement or pain." That is to say, she was not only completely blind in the left eye, but the

orbicularis was paralysed, the lids, conjunctiva, and cornea were anæsthetic, and the conjunctival and corneal reflexes were abolished. In the next six months the patient gradually regained the use of her arm and leg, but the condition of the eye had remained unaltered when, nearly ten years later, she had a second attack, which again affected her left side, and from which she again recovered. She was scarcely convalescent when she was struck down a third time, but on this occasion the paralysis of the left side was complete. The arm hung useless by her side and she could only move with difficulty, dragging her useless left leg behind her. The muscles of the arm and leg became atrophied and the skin œdematous. Being convinced that no human resources could help her, and recalling how she had heard of one, Anne Angier, who had been cured of paralysis, which had affected her for 21 years, as a result of the intercession of M. Rousse, she determined to visit his tomb in the Chapelle de Ste. Anne at Avernai. She was fortified in this resolution by a dream, which she took for a message from heaven. It seemed to her that she had been transported in the night to the tomb of M. Rousse, and that there the most perfect recovery had suddenly been vouchsafed to her."

On May 16th, 1728, in spite of the opposition of the church authorities because Rousse had not been canonised, she visited his tomb. Here she was suddenly seized with violent pain in her hand and eye. Strength returned to the left hand, so that she could join it with the right in prayer, and to her leg, so that she could kneel. The eye, which had been blind for ten and a half years, recovered its sight, its power of movement, and its sensibility. The recovery from the hemiplegia, hemianæsthesia, and blindness was complete, and there had been no relapse when Carré de Montgeron wrote his "Vérité des Miracles" 19 years later.

NARROW AND SPIRAL FIELDS OF VISION IN HYSTERIA, MALINGERING, AND NEURASTHENIA.

Retraction of the field of vision has been regarded as the most characteristic "stigma" of hysteria since Charcot first drew attention to it in 1872. Janet⁸ considered it to be "the emblem of hysterical sensibility in general," and it led him to describe hysteria as a condition due to "retraction of the field of consciousness." Among ophthalmologists de Schweinitz⁹

FIG. 8.—Right eye, without-inward spiral field in case of hysterical paraplegia.

regards this sign as "a permanent stigma" of hysteria, and believes its value as an aid to diagnosis to be "exceedingly great." But Babinski¹⁰ found no change in the field of vision in any of a series of a hundred consecutive cases of hysteria, examined in great detail by methods which excluded the possibility of suggestion. Morax,¹¹ a former assistant of Charcot, from whom he learnt the supposed significance of the retracted field of vision, at first continued to find it in almost every patient suffering from hysterical symptoms. But over 20 years ago he

became a convert to Babinski's views, and since then he has not seen a single case of hysterical retraction of the field of vision. As it is almost impossible to avoid suggesting a narrow field of vision with the perimeter in highly suggestible individuals, he estimates the fields with the finger or other familiar object in hysterical patients, and although this may appear at first to be less accurate, it has the great advantage of making it easy to avoid suggesting abnormalities in the course of the examination.

FIG. 9.—Spiral fields in case of hysterical tremor. (A) Left eye, within-outward spiral field. (B) Right eye, within-outward spiral field.

In spite of the comparatively frequent occurrence of the various hysterical disturbances of vision I have already described, I have never seen patients with hysterical symptoms affecting other parts of the body who spontaneously complained of disabilities resulting from a narrow field of vision, however closely they were cross-examined on the subject. But if a narrow field of vision is produced by testing with the perimeter the patient may subsequently complain of considerable inconvenience as a result of the cutting off of his peripheral vision.

In association with Major J. L. M. Symms¹² I examined numerous soldiers suffering from various war neuroses, who were abnormally suggestible as a result of the stress and strain of active service, some, but not all, of whom were suffering from gross hysterical symptoms. We never found any retraction of their field of vision until the perimeter was used. But the perimeter invariably resulted in the suggestion of a narrowed field, however carefully it was used. Moreover, if the examination was continued after the first field was marked out a spiral field was always obtained (Fig. 8) identical with that which has hitherto been regarded as a stigma of hysteria. We believe that the reason why a spiral field of vision, which is the natural result of continued suggestion, has not been found in a larger proportion of hysterical cases showing a narrow field of vision is simply because it has not been looked for, the examiner being content when he has marked the limit of vision a single time in each direction.

It has generally been taught that a spiral field of vision is a result of fatigue, and it has even been stated that it is more frequently a symptom of neurasthenia than of hysteria. We have found that this is not the case, the inward spiral, which has hitherto alone been described, being a result of the method employed in using the perimeter. An outward spiral is always obtained instead of an inward one if the white disc of the perimeter is moved outwards instead of inwards, as is commonly done. (Fig. 9.) By varying the direction in which the disc was moved we could produce an inward spiral one day and an outward spiral another day with the same eye, or an inward spiral with one eye and an outward spiral with the other at the same time. (Fig. 10.) There is no question of any special suggestions made by us in our method of using the perimeter, as identical results were obtained by other observers, who marked out the fields of vision for us without knowing the nature of the cases or the object we had in view in obtaining the tracings. Moreover, we have always obtained normal fields in normal individuals, whether the disc was moved inwards or outwards.

In the observations on "experimental malingering," which I described in my first lecture, we asked 27 individuals, who were pretending to be paralysed on the right

side, and none of whom had mentioned any disturbance in vision when detailing their symptoms, whether they could see as well with the right eye as the left; seven replied that they had noted some impairment of vision in the right eye. On testing the field of vision with a finger no narrowing was observed, and they explained that the deficiency they had spoken about was a blurring or general loss of clearness of vision. But when tested with a perimeter all of the seven showed a narrow field on the right side, and one had a slighter narrowing on the left side. In the only two cases in which it occurred to us to continue the investigation after the first field had been marked out a spiral was obtained (Fig. 11), which was identical in character with that supposed to be characteristic of hysteria.

Ocular Aura in Hysterical Fits.

I have seen several cases of hysterical attacks which were preceded by a visual aura. Most of the cases in soldiers dated from a period of strenuous activity in the glare of Mesopotamia. In the following case, in which the attacks consisted of headache and loss of consciousness and not of epileptiform convulsions, an understanding of the psychological processes involved resulted in immediate recovery from a very incapacitating condition which had persisted for two years.

Hysterical photophobia with attacks of headaches and loss of consciousness.—Captain S. was wounded in the head in 1915. He was temporarily paralysed on the right side and suffered from violent headaches, which culminated in loss of consciousness. He gradually improved, and no more attacks occurred after the end of 1916. He went back to France in 1917. Soon afterwards he had some acute mental disorder, for which he was in hospital for five months; after this he was invalided out of the service, but was fit enough to be sent to Greece on diplomatic duty. In 1918 he went to Salonica for an operation to be performed on his heel. Some other appears to have been accidentally dropped into his eyes during the operation,

followed by a headache, he subconsciously associated this with the headaches which had followed the wound to his head, and that he had consequently suggested to himself the same sequel—loss of consciousness. The attacks of headache followed by unconsciousness now became associated in his mind with his eyes instead of with the original injury to his head. Consequently an attack occurred every time he removed his dark glasses, and for this reason he feared to face the light. The blepharospasm and deficient sight were produced in the way I have already described in connexion with the hysterical disorders of vision caused by gassing. Having discussed this explanation with him in great detail I promised him he would recover completely when he came to me for treatment the next day. He arrived fully convinced he

FIG. 10.—Spiral fields in case of hysterical mutism and tremor. (A) Left eye, without-inward spiral field. (B) Right eye, within-outward spiral field.

would be cured, having thoroughly grasped the explanation I had given him of the origin of his symptoms. Without difficulty I persuaded him to remove his dark glasses, keep his eyes widely open, and accommodate his vision for near and distant objects. For the first time for two years he was able to keep his eyes open without getting a headache, and an hour later he went for a walk in the sun without glasses. In the four months which have elapsed he has had no further attacks of headache and loss of consciousness. He has just married and is shortly returning to his diplomatic duties.

I believe that hysterical fits are much more common than is generally supposed, and that many such cases are diagnosed as epilepsy and treated for years with bromides. It has been said that a definite aura is uncommon in hysteria, but common before true epileptic fits. I am convinced that this is incorrect, and that some kind of warning invariably precedes a hysterical attack. It is indeed this "warning," which acts as the suggestion, which is the exciting cause of each fit. A symptom which has once produced an attack will be likely to produce another whenever it recurs, because it subconsciously reminds the patient of his earlier attack and thus suggests that another will occur.

as when he came round from the anaesthetic he found his eyes were so painful that he could not open them, and he thought he had lost his sight. At the end of a month he could see a little, but he could not read and had always to wear the darkest glasses he could get, as directly his eyes were exposed to the daylight he had a violent headache, which was followed in a few minutes by complete loss of consciousness.

I first saw him in February, 1920. It was very difficult to examine his eyes as he kept them tightly closed. When the dark glasses were removed, or even when he was wearing them, he never opened his eyes widely, but he could see enough to get about without assistance. He was very depressed about his condition. His arm and leg were quite well, and there were no physical signs of organic disease. There was a slight depression of the skull in the region of his wound, but it was not tender and there was no bony deficiency.

I explained to the patient that when the removal of the bandages from his eyes for the first time after they had been injured was

DONATIONS AND BEQUESTS.—The late Mr. John William Barclay, of Manchester, by his will left £1000 each to the Manchester Royal Infirmary and Dispensary and the Salford Royal Hospital; £500 each to the Ancoats Hospital and Ardwick and Ancoats Dispensary, Manchester Hospital for Consumption, Manchester Royal Eye Hospital, Manchester Children's Hospital, Pendlebury, St. Mary's Hospital, Manchester, and the British Hospital, Buenos Aires.

AN INVESTIGATION INTO THE CAUSAL ORGANISM OF INFLUENZA.

By J. W. EDINGTON, M.D. EDIN., D.P.H.,

LATE CAPTAIN, R.A.M.C.; OFFICER IN CHARGE OF THE DISTRICT
MILITARY LABORATORY, SHORNCLIFFE.

THE following deals with the investigation of three small epidemics, as well as a few sporadic cases of what clinically appeared to be influenza, in the Shorncliffe area during the months of February, March, and April, 1920.

The object of the investigation was to try to find out the causal organism.

These cases appeared in four definite centres, viz.:—

1. Canterbury.—This was a sudden, though mild, epidemic during the first three weeks of March, 1920. It attacked the 10th Hussars, and infected a large number of them. The majority suffered very slightly, and there were only between 20 and 30 cases admitted to hospital. Here they infected a few more of the hospital patients. Of these 17, who appeared clinically to be suffering from influenza, were investigated.

2. Dover.—This was a similar epidemic to that at Canterbury. It occurred during the first three weeks of April, 1920. It affected both the Royal Irish Fusiliers and the Connaught Rangers. Of the hospital cases I investigated 6.

3. Shorncliffe.—Here the cases were entirely sporadic, and were spread over the months of February, March, and April, 1920. The number investigated was 8.

4. Hythe.—This epidemic was sudden and short-lived. It developed only in the Small Arms School, and appeared to have been brought there by new arrivals from other areas. It occurred during the last two weeks of April, 1920. The number of cases investigated was 9.

Before commencing the study of these cases it might be of interest to draw attention to the enormous fallacies present in the so-called influenza returns. The diagnosis, depending as it does in most cases entirely on clinical evidence alone, naturally tends to great errors. Cases may be labelled under any number of names—e.g., migraine, headache, tonsillitis, bronchitis, laryngitis, rheumatism, &c. The converse also holds good, as a large number of diseases, more especially during and immediately after an influenza epidemic, are conveniently and popularly diagnosed as influenza. This naturally cannot be helped in the present state of our knowledge regarding the disease, but ought to make one very chary in accepting any statistics or statements based on these returns.

(1) CLINICAL SIGNS AND SYMPTOMS.

These coincided in the cases derived from the Canterbury, Dover, and Shorncliffe areas, but were slightly different in those from the Hythe epidemic.

In the Canterbury, Dover, and Shorncliffe areas the cases showed the following characteristics: (1) Sudden onset in all; (2) rise of temperature in all; (3) pulse-rate increased in correspondence with the rise of the temperature (i.e., if the case was not complicated); (4) respiratory rate depended on the amount of lung involvement; (5) headache in 93 per cent.; (6) pains in limbs, back, or chest in 80 per cent.; (7) suffusion and injection of eyes in none = 0 per cent.; (8) coryza in 36 per cent.; (9) bronchitis in 83 per cent.—this usually did not develop until two to four days after the onset of the illness; (10) tonsillitis and pharyngitis in 80 per cent. (marked, often patient's chief complaint); (11) laryngitis (late in development) in 6 per cent.; (12) herpes labialis in 33 per cent.

In this series of cases there was only one death. This occurred from a secondary septic broncho-pneumonia in one of the Dover cases. The complications were as follows:—

Three cases developed broncho-pneumonia, and of these one died.

One case is suspected of having developed tuberculosis of the lungs.

One case developed diphtheria.

" " " dementia præcox.
" " " subacute rheumatism.
" " " furunculosis.
" " " nephritis.

In the Hythe cases the following characteristics were noted: (1) Sudden onset, occasionally with history of a slight rigor; (2) rise in temperature in all;

(3) increase in pulse-rate corresponding to the rise in temperature (i.e., if a non-complicated case); (4) respiratory rate depended largely on the lung involvement; (5) headache in 100 per cent.; (6) pains in limbs, back, or chest in 77 per cent.; (7) suffusion and injection of the eyes was present in 100 per cent., the facies was characteristic, and the watery, bleary appearance of the eyes reminded one of an early case of measles; (8) coryza in all = 100 per cent.; (9) bronchitis in all = 100 per cent.; (10) tonsillitis and pharyngitis in 44 per cent. (never marked); (11) laryngitis in none = 0 per cent.; (12) herpes labialis in none = 0 per cent.

In the Hythe cases there was one death from septic broncho-pneumonia. This patient showed marked cyanosis, and reminded one of the picturesque description of the laity—viz., "purple or blue influenza."

It will be seen that clinically the cases divide themselves into two classes: (1) Those from the Hythe epidemic showed marked eye symptoms and slight throat involvement. (2) The other cases from the other areas showed by contrast marked throat involvement, but no eye symptoms.

Bacteriologically, the organisms isolated as *B. influenza* (Pfeiffer) correspond to the following description:—

In size they were from 1.0 μ to 2.0 μ in length by about 0.4 μ in thickness. They do not occur in chains; but in subcultures, especially if old, filamentous forms sometimes appear. I am inclined to think that the organisms which tend to produce filamentous forms on subculture belong to a definite group of the influenza bacillus, as some varieties, no matter how long subcultured, will never produce filaments.

They stain feebly with basic aniline dyes, and are best stained with either: (a) weak solution (1 in 10) of carbol-fuchsin for five to ten minutes, or (b) a strong solution of carbol-fuchsin for from one to two minutes. The organism is definitely Gram-negative, non-motile, and non-sporing.

Bacillus influenza (Pfeiffer) grows very well on boiled blood agar, feebly on blood-smear agar, and not at all on subculture on ordinary agar.

The optimum temperature for growth is about 37° C. After 24 hours' growth on boiled blood agar the organisms begin to show a variety in their staining reaction, some bacilli taking the stain strongly, whilst others stain very feebly.

The boiled blood agar medium was eminently satisfactory. It was found that growth was most luxuriant on a slightly moist medium; therefore plates were left only 24 hours in the 37° C. incubator before being inoculated.

The standard of reaction of the agar used was that with a P_H value of 7.4 to 7.8.

In some cases the medium was titrated with equally successful results by the Eyre method. In these cases it was standardised to +10 Eyre scale. Tubes of the agar were melted by boiling in a saucepan, and about 1.0 c.cm. of sterile human blood directly added to each tube. This was well shaken to prevent lumps forming and boiled for from two to three minutes in the saucepan. The medium was then ready for pouring into plates or sloping in large tubes (6" x 1"). The latter method was most successful, as there was not nearly as much medium wasted by contamination as with plates. The tubes were always used whenever the organism had been isolated in pure culture.

On boiled blood agar, after cultivation for 24 hours at 37° C., the colonies of the influenza bacillus appear as moist, greyish, "filmy" colonies. These vary from the size of a pin's head to colonies with a diameter of 3 mm. The edges are regular and the outline is circular. The larger colonies show a typical umbonate appearance.

When touched with a platinum loop the colonies appear of a slimy character and can be easily emulsified in normal salt solution. As they become older they become drier and more friable.

The method of examining the cases for the presence of *B. influenza* was by means of West's post-nasal swabs, as used in cerebro-spinal fever work.

At the commencement of the investigation 200 men were examined to find out the carrier-rate. These were swabbed in three ways—viz.: (a) Anterior nasal route; (b) post-nasal route; (c) ordinary throat swab.

The largest number of positives were obtained by the post-nasal method, the smallest by the anterior nasal method. Thus the post-nasal method was adopted as a routine.

Boiled blood agar plates were immediately inoculated and kept in special carriers at a constant temperature of 37° C. until the laboratory was reached, when they were at once

deposited in the 37° C. incubator, and left there for 24 hours. The plates were then examined and likely colonies picked off. Next day these subcultures were stained by Gram's method, and if satisfactory were subcultured until absolutely pure. During this process an agar plate was always inoculated to see if any growth took place. No organism which on subculture grew on ordinary agar at 37° C. was regarded as *Bacillus influenzae* (Pfeiffer).

The pure cultures were used for the preparation of various antigens and emulsions. If no influenza bacillus was cultured from the suspected case at the first swabbing this was repeated twice before a negative result was accepted. This definitely increased the number of positives obtained. Thus of 20 positives—

16 were found positive from the first swab = 80 per cent.

3 " " " " " second " = 15 "

1 was " " " " " third " = 5 "

In the last case the trouble was the presence of a contaminating organism in the throat which rapidly overgrew the whole plate.

The examination of direct films was also tried. This gave an idea of the relative proportion of the *B. influenzae* to the other organisms in the naso-pharynx. It, however, was found that some cases which were negative for *B. influenzae*, as examined by the direct film method, were positive on culture.

Results of Swabbing in the Four Centres.

The results of swabbing in the four centres were as follows:—

Canterbury cases.—In all 17 cases were examined, and all were found positive. In 15 absolutely pure subcultures were eventually obtained. In 2 the organism unfortunately died out before a pure culture could be obtained. In these cases the most troublesome contaminating organism was a small hæmolytic streptococcus which appeared to grow in the midst of, as well as around, the influenza colonies.

Dover cases.—These were six in number, and all were found positive. In the case that died a pneumococcus was also isolated. This latter case was difficult to investigate, as far as the throat swabbing was concerned, because of the presence of a rapidly growing large Gram-negative bacillus.

Shorncliffe cases.—Eight cases were examined. Seven were positive and one was persistently negative in spite of frequent examinations. It was diagnosed as due to infection by the *B. influenzae* on the clinical signs plus the positive agglutination and complement-fixation results. Taking the cases from these three areas, which were 31 in number, one finds that *B. influenzae* was isolated from the naso-pharynx of 30—i.e., a percentage of 96·8 per cent. positive.

Hythe cases.—The result of the investigation of this epidemic came more or less as an anticlimax to the previous work, as one had begun to expect to find *B. influenzae* in the large majority of suspected cases. Here nine cases were investigated. *Bacillus influenzae* was found in only one, and here, I think, not as a causal agent of the disease, but merely as a component of the naso-pharyngeal bacterial flora. The reason for this statement being that this case yielded negative results to both agglutination and complement-fixation tests. Further, as the carrier-rate for *B. influenzae* in that area at the time of the epidemic was 8 per cent., the presence of one positive throat swab in nine cases was to be expected. Of the other organisms present the only one which was common to all was a Gram-negative diplococcus which showed the following characteristics. It grew well on blood agar at 37° C. In staining by Gram's method it was rather difficult to decolorise in young cultures (up to 24 hours), but was easily decolorised in older cultures. It was very difficult to emulsify in saline. It gave no agglutination with any of the types of meningococcal agglutinating sera. It gave no agglutination with any of the sera obtained from five of the cases. Complement-fixation tests were not tried.

Its cultural characteristics were as follows:—No liquefaction of gelatin (up to ten days) at 20° C.; granular deposit in peptone water, and bouillon; no production of indol; acid in glucose and maltose; no change in dextrose, inulin, lactose, mannite, saccharose, dextrin, galactose, adonite, sorbite, lævulose, raffinose, and arabinose up to ten days. It was non-hæmolytic on blood media. No change was noticed in litmus milk after ten days' incubation at 37° C. In the case that died, besides the above-mentioned coccus, a hæmolytic streptococcus, a pneumococcus, and a staphylococcus were isolated from the naso-pharyngeal swab.

(2) AGGLUTINATION RESULTS.

The agglutination of the isolated organisms by means of the patients' sera was next investigated. The well-known Dreyer's technique was used.

The emulsion was made from a culture which had been subcultured daily for from six to eight times. Enough was made up at once for all purposes, as it was impossible to

keep so many subcultures growing at the same time. It was found that heating the emulsion for one hour at 58° C. diminished its agglutinability, and that a slightly more opalescent emulsion than that of the usual standard agglutinable cultures for the typhoid group of organisms gave the best results.

The emulsions were preserved by means of 0·1 per cent. formalin. The agglutination was carried out in an incubator at 55° C. for from 24 to 36 hours, care being taken to keep the atmosphere in the incubator moist. In some few cases an incubation of 36 hours appeared essential to get the best results. As a routine the tubes were examined at the end of 24 hours, and after the results had been noted they were replaced for another 12 hours, and again examined. The type of agglutination varied a great deal, sometimes being of a coarse character with heavy flocculi, whilst in others it was of a fine granular type.

The dilutions used were 1 in 25, 1 in 50, 1 in 150, and 1 in 250.

In all cases a saline control was put up as well as a known positive and known negative.

The following were the emulsions used:—Ha., Ed., Up., Kn., Ke., Bo., St., Cu., Pa., Ta., Dr., Di., Tr., Ha., Bu., Ne., Ca., El., Ke., Pa., An., Se., Ph., Ly., Bo., As., Fo., Mu., Du., 63, 407, 126, 203, 65, 67, 78, 36, 49. The numbered emulsions were obtained from some of the organisms derived from positive carriers of *B. influenzae*. To simplify the description the results will be put in tabular form.

The 17 cases given in Table I. were those examined from the Canterbury area. The only ones which showed any agglutination were those in which the temperature was still elevated when the blood serum was examined. The others, where the blood was withdrawn during convalescence, showed definite negative results. The possibility of the organisms isolated being poor for agglutination purposes was recognised, and it was proposed to examine any further cases, not only during the time of the fever, but, if possible, again during convalescence. The next series of cases examined were from the Dover area. The tabulated results are as given in Table II.

Table II. hardly needs any explanation. Agglutination appears in all these cases. The results as far as the emulsion of Ly., Fo., and An. are concerned must be disregarded, for, as will be shown later, they gave non-specific agglutination with normal sera. Thus agglutination in the above cases appears to be present early in the disease, and from consideration of the Canterbury series it seems to rapidly disappear immediately the temperature has fallen. Some emulsions, such as those of El., Mu., and Pa. are much more easily agglutinated than the others.

The agglutination results in the Shorncliffe cases (Table III.) corroborate the findings in the Canterbury and Dover cases. In order to clinch the statement that influenza agglutinins rapidly disappear from the blood during convalescence blood was again withdrawn from some cases during convalescence, and compared with the agglutination results obtained from the same blood sera withdrawn during the fever. The results are shown in Table IV. The serum of Mu. was inserted by way of being a control. The temperature was still up when the serum was withdrawn and the case was a pretty severe one. The agglutination titre had risen. In the other cases it is seen that without exception the influenza agglutinins in the blood had rapidly disappeared soon after the temperature had fallen.

The next series of cases to be examined were those from the Hythe epidemic. In only one case—viz., Du.—was the *B. influenzae* isolated from the throat swab. Blood could only be obtained from five of the cases—viz., Pa., Du., McG., Ea., and Pe. The results are given in Table V. In none of these cases, though the blood was withdrawn at the most favourable time, was there any agglutination with emulsions of known agglutinable strains of *B. influenzae*.

Controls.—Next all the emulsions which gave positive agglutination results in the above-mentioned cases from all areas were tested with 20 normal sera. The emulsions of Fo., An., and Ly. gave numerous non-specific agglutinations, and are therefore to be disregarded in reading any of the above-mentioned results. The emulsions of Ha., Cu., El., Mu., Ke., Bo., Pa., 126, and 203 gave no agglutination in any dilution of from 1 in 25 to 1 in 250 with the control sera. It is, therefore, concluded that these emulsions are only

agglutinated by sera containing specific agglutinins for *B. influenza* (Pfeiffer).

Conclusions Derived from the Agglutination Work.

That in those cases derived from the Canterbury, Dover, and Shorncliffe areas, (a) specific agglutinins for *B. influenza* (Pfeiffer) appeared early in the disease (in some cases at the third day); (b) these agglutinins disappeared rapidly when convalescence set in—i.e., when the temperature had again become normal.

Regarding the *B. influenza* from an agglutination point of view: (1) A large number of strains are non-agglutinable when tested with sera derived from cases at all stages of the illness. (2) Some few types are easily agglutinated; they do not appear to be differentiated into any particular definite classes, but it must be remembered that all these cases occurred in one district and were probably all of the same origin. I had not the opportunity of testing the blood sera against strains derived from other remote districts. (3) Some bacilli isolated gave non-specific agglutination—thus the advisability of control sera.

Now, regarding the Hythe epidemic, *B. influenza* was isolated from one case only (Du.). In none of the cases was any agglutination obtained with emulsions of *B. influenza*. The one case was regarded, as far as the presence of the *B. influenza* was concerned, as a carrier of that organism.

A Gram-negative diplococcus was isolated in all the cases, and an emulsion prepared from each. These emulsions were put up with sera from 5 of the cases in dilutions of 1 in 25 to 1 in 250. In no case was there any agglutination. The sera used were from the cases Pa., Du., McG., Ea., Pe. The emulsions used were made from the diplococci isolated from the following cases: Pa., Du., McG., Bl., Ea., Mrs. Ea., Pe., and Mrs. Pe.

The negative agglutination results do not support the view of the diplococcus being the causal organism in this epidemic.

(3) COMPLEMENT FIXATION.

The usual technique was employed. The main details of this were as follows:—

The fixed volume in each tube was always 3 c.cm. The washed sheep's blood corpuscles were used in a 3 per cent. suspension. The hæmolytin was titrated before each experiment to find out its minimum hæmolytic dose (M.H.D.). In the titration of the antigens, as well as in the tests proper, a dose of 2 M.H.D.'s of hæmolytin was used—i.e., the hæmolytic couple consisted of 1 c.cm. of a 3 per cent. suspension of washed sheep's blood corpuscles, in which there was also contained 2 M.H.D.'s of hæmolytin.

The complement was 1 c.cm. of a 1 in 20 dilution of fresh guinea-pig's serum in saline (0.85 per cent.). The remaining 1 c.cm. in the tubes consisted of the varying amounts of antigen, patient's serum, and saline.

The antigens used were three in number. They were polyvalent, and were found to give exactly the same results.

The method of preparation was simple. The various strains were cultivated for 48 hours on boiled blood agar at 37°C., and the resulting growth washed off with saline solution. Care was taken not to include any of the medium. The emulsion was well shaken up in order to make it homogeneous and heated for one hour at 58°C. in the water-bath; 0.5 per cent. carbolic was then added as a preservative.

* Refused to have blood withdrawn.

In most of the cases examined all three antigens were used. In no case were ever less than two used. They were composed of organisms isolated from the following cases.

Antigen 1.—Ha., Up., and Ed.

Antigen 2.—Kn., Ke., Bo., St., Cu., Fa., Ta., Dr., Di., Tr., Ha., Bu., Ne., Ca., Ed., Ha., and Up.

Antigen 3.—Fo., As., Mu., Se., An., Ph., Ly., Bo., Pa., El., and Ke.

After the M.H.D. of the hæmolysin had been determined the antigens to be used were titrated to find out their anticomplementary dose. After much work with normal sera and sera from influenza cases it was found that the best dose of antigen to use was one-quarter of the anticomplementary dose. Any higher dose, say $\frac{1}{2}$ or $\frac{3}{4}$, of the anticomplementary dose produced an increasing number of false positive reactions amongst the controls. As the amount of fixation of complement was never great, it was essential to use the very utmost of care in the test if a really accurate result was to be obtained.

The patient's serum was used (after inactivation at 55° C. for half an hour) in doses of 0.05 c.cm., 0.1 c.cm., and 0.2 c.cm. A serum control of 0.4 c.cm. was always put up. Fresh sera were used as an old negative sera, though perfectly sterile, occasionally gave positive results.

In the test proper the following tubes were put up:—

Tubes 1, 2, and 3 were concerned with the testing of the varying amounts (0.05 c.cm., 0.1 c.cm., and 0.2 c.cm.) of the unknown serum.

Tube 4 was the serum control (i.e., containing 0.4 c.cm. of patient's serum).

Tube 5 was the antigen control. (Three times the dose of the antigen was used—i.e., three-quarters of the anticomplementary dose).

Tube 6 was the hæmolytic control (i.e., corpuscles + hæmolysin + complement).

Tube 7 was the corpuscle control (i.e., corpuscles + hæmolysin).

Tube 8. A known positive serum.

Tube 9. Serum control of known positive serum.

Tube 10. A known negative serum.

Tube 11. Serum control of known negative serum.

Tube 12. Weak positive serum.

Tube 13. Serum control of weak positive serum.

The latter two tubes I consider most important as they give one a very good idea of the accuracy of the test.

Twenty normal sera were used as controls and all gave negative results except two, viz.:—

(a) Faint positive—i.e., — +. This patient gave a history of influenza a year ago.

(b) Moderately strong positive + +. This man said he had influenza one month previously.

The control sera were mainly from venereal or suspected venereal cases—e.g., syphilis, gonorrhoea, soft sores, and venereal warts.

The exceptions were as follows: Psoriasis, malaria, tuberculosis, nephritis, and acute otitis media, of each one case.

The results are given in Table VI.

Conclusions.

The results, taken along with the results of the examination of the 20 control sera, are decidedly in favour of the reaction being specific in character.

The cases from the Hythe epidemic—viz., numbers 32, 33, 34, 35, and 36 in the above table—gave negative results. This is another point against *B. influenza* being the infective agent in these cases.

Of the other cases which appeared by cultural and agglutination results to be due to *B. influenza*, 21 out of 30—i.e., 70 per cent.—gave positive results. It appeared in some cases as early as the third day of the illness.

Of the cases (12) examined during the first week of the illness 91.7 per cent. were positive. Of the cases (7) examined during the second week of the illness 57.1 per cent. were positive. Of the cases (11) examined during the third week of the illness 54.5 per cent. were positive.

This shows that the number of positives is at its greatest during the first week of the illness, rapidly diminishes during the second week, and then slowly continues falling during the third week.

Of the controls, as above mentioned, quite a strong positive was obtained in one man a month after an attack of influenza, and a feeble positive in another case one year after an attack. There appears to be no relationship between the severity of the attack and the amount of complement fixed.

(4) THE MIOTAGMIN REACTION.

This test is mainly used in the diagnosis of cancer, but has also been used with success in the diagnosis of some bacterial infections—e.g., typhoid, tuberculosis, &c. It was decided to try it in the diagnosis of influenza. As this test is not well known in this

country it will perhaps be an advantage to give a more detailed account of the technique than has been given in the case of the agglutination and complement-fixation work.

The reaction is a surface tension phenomenon, the exact mechanism of which is not understood. It depends on the fact, as first noticed by Ascoli, that when an antigen is brought into contact with its corresponding antibody there is a reduction of the surface tension of the fluid containing these. This change is ascertained by means of a dropping pipette of great accuracy. Such an instrument was marketed under the name of a Traube's stalagmometer. I could not obtain the latter instrument, but am indebted to Messrs. Hawksley, London, for the production of a very satisfactory substitute.

A fixed amount, usually 1 c.cm. of the fluid to be tested, is drawn up into the pipette and its drop number ascertained. The antigen is prepared and used in such a dilution that it does not increase the drop number of normal serum beyond one drop for 1 c.cm. The drop number of the stalagmometer I used was just a trifle low (45 per 1 c.cm. of distilled water), but it gave most accurate readings. The stalagmometer was rigidly fixed up in a vertical position (ascertained by use of a plumb line) by means of two burette stands fixed up at right angles to each other and screwed down to a solid bench. The arms of the burette stands grasped the stalagmometer firmly at two points about 2 inches apart, and thus prevented any movement of that instrument in any direction.

A mark was made on the bench where the drop from the stalagmometer should fall, and the apparatus was always tested by this means before use. The maximum error allowed after numerous tests was 0.25 of a drop in 1 c.cm. of distilled water.

All glassware used was scrupulously clean. The tubes were never plugged with cotton-wool as the fibres of the latter interfered with the accuracy of the test. The stalagmometer after use was cleaned out with distilled water, alcohol, and ether. The latter was got rid of by means of a current of hot air.

The most important part of the test was the preparation of a suitable antigen. Three in all were prepared and used.

1. Twelve 48 hours' boiled blood agar plates of *B. influenza* were washed off with a total of 25 c.cm. of sterile normal salt solution. This emulsion was covered with toluol, and the whole well shaken for four hours. It was left in the incubator at 37° C. for 48 hours, and then filtered through a Chamberland "F" filter (sterile). This filtrate was used as Antigen 1.

2. This antigen was prepared as above, but the filtrate was extracted with 50 c.cm. of absolute alcohol for half an hour and then centrifuged. The deposit was again extracted with 20 c.cm. of absolute alcohol in a similar manner. The supernatant fluids from both extractions were combined and concentrated to 20 c.cm. by means of a water bath. This was used as Antigen 2.

3. The growth from 48 hours' old cultures of *B. influenza* grown at 37° C. on boiled blood agar was scraped off, and dried at 37° C. on glass plates. On scraping off the growth care was taken not to include any of the medium; 0.5 g. of the resulting dried bacilli was ground up in a mortar and extracted with 20 c.cm. of methyl alcohol. This was filtered through a sterile Chamberland filter, and the filtrate was used as Antigen 3.

The three antigens were titrated in varying dilutions—viz., pure, 1 in 5, 1 in 10, 1 in 20, and so on to 1 in 200. The fluid used for dilution was distilled water. A fresh normal serum was used in a dilution of 1 in 20 in normal salt solution to standardise the antigens.

In a series of perfectly clean tubes 9 c.cm. of the diluted serum were mixed with 1 c.cm. of the varying dilutions of the antigen to be tested. A control of 9 c.cm. of the diluted serum and 1 c.cm. of distilled water was put up. The tubes, after having been shaken, were put in the 37° C. incubator for two hours; these were then removed and the drop number of their contents ascertained when under similar temperature and pressure conditions. The antigen used was the strongest dilution which did not increase the drop number for normal serum beyond one drop for 1 c.cm. All the sera were tested in a similar manner. In no case was a positive result obtained—i.e., increase in the drop number.

Conclusions.

The apparatus was thoroughly satisfactory and accurate. The results point to one of two things—

1. That no miostagmin for *B. influenza* (Pfeiffer) was present in the sera tested; or—
2. That the antigens were not satisfactory. I have not been able to settle this point, as I have not as yet succeeded in getting an antigen to give a positive result with the serum from an influenza case.

(5) CARRIER QUESTION.

At the request of the Assistant Director of Pathology, Eastern Command, I did sample swabbing of the troops in this area to find out the carrier-rate for *B. influenza*. The results were as given in Table VII.

TABLE VII.

Date of swabbing.	Station.	Unit.	Number swabbed	Percentage.
11/2/20	Shorncliffe.	Hospital patients.	50	8%
13/2/20	Dibgate Camp.	M.G.C.	50	8%
15/2/20	Moore Barracks.	M.G.C.	50	14%
17/2/20	Ross Barracks.	R.F.A.	50	8%
21/2/20	Dover.	R.I.F.	50	14%
25/2/20	Dover.	R.W. Kents.	50	14%
4/3/20	Canterbury.	10th Hussars.	50	18%
4/3/20	Canterbury.	Bufis.	50	18%
13/3/20	Shorncliffe.	Hospital patients.	50	16%
19/3/20	Canterbury.	10th Hussars.	50	6%

This table is interesting when taken along with the occurrence of the epidemics. At the beginning of the Canterbury epidemic amongst the 10th Hussars the carrier rate was 18 per cent. At the end of the epidemic the carrier rate had fallen to 6 per cent.

It appears as far as one can judge from the small number of troops examined that a carrier rate approaching 20 per cent. indicates a danger of an epidemic. The powder, as it were, is there, but what puts the match to it is difficult to find out. One point noticed was that the epidemics at both Dover and Canterbury coincided with a spell of cold wet weather.

Inoculation as a Prophylactic Measure.

Between 700 and 800 were done personally. The reaction in healthy persons was in all cases remarkably mild. If, however, as was done in six cases, the inoculation is made when the person is suffering from an attack of coryza or bronchitis, no matter how slight, the symptoms were always markedly aggravated. In my own case I was suffering from a slight coryza when I gave myself the second dose. This became much worse, and developed into a mild attack of influenza. It was not recognised as such, until after about a week the nasal discharge became of a bright canary-yellow colour.

The colour excited my curiosity, and on culturing on boiled blood agar I got an absolutely pure growth of *B. influenza*. Whether I was a carrier or suffering from a slight coryza due to *B. influenza* before the inoculation, or whether I caught the infection after the injection (I was working amongst influenza cases at the time), I am unable to say.

Regarding the efficacy of the vaccine I have still an open mind. Influenza returns I disregard on account of the fallacies involved. It may be of interest to note that at Canterbury the 10th Hussars were practically entirely non-inoculated at the time of the epidemic, whilst at Dover the Royal Irish Fusiliers had been practically entirely inoculated quite recently—i.e., within two months. The severity of the attack was to all appearances the same in both units.

If the vaccine be given to a healthy person it certainly does no harm, and as there is a difference of opinion as to whether it does good or not I always recommend it.

(6) FINAL CONCLUSIONS.

From the work done it would appear that one would be quite justified in claiming that the *B. influenza* (Pfeiffer) was an infecting agent in all the Dover, Canterbury, and Shorncliffe cases. To go further, one can say that it was likely to have been the primary infecting agent, seeing that specific agglutinins and complement-fixing bodies were demonstrated in the blood of some cases as early as the third day of the

illness. The cultural results, as well as a consideration of the fluctuations of the carrier rate, also favour the statement that *B. influenza* (Pfeiffer) was the causal organism.

In the Hythe cases *B. influenza* (Pfeiffer) does not seem to have been the causal agent, as has been shown both culturally and serologically. I should be chary in accepting the Gram-negative diplococcus, isolated in all the cases, as the causal agent until the cultural results were supported by some immunity test.

The whole work tends to point to the fact that clinical influenza may be due to more than one variety of infecting organism.

TREATMENT OF CHRONIC OTORRHOEA BY ZINC IONISATION.

By A. R. FRIEL, M.D. DUB., F.R.C.S. IREL.,

CLINICAL ASSISTANT, THROAT AND EAR DEPARTMENT, ROYAL FREE HOSPITAL; LATE HONORARY PHYSICIAN FOR THE THROAT, NOSE, AND EAR, GENERAL HOSPITAL, JOHANNESBURG.

OTORRHOEA as a result of middle-ear disease may persist after the acute stage has passed owing to:—

(a) Irritation from accumulation of septic fluid in the tympanum proper—tympanic sepsis.

(b) Tympanic sepsis complicated by: (1) polypi and granulations, or carious bone in the middle ear; (2) overflow of septic fluid into the tympanum from adjacent parts—e.g., mastoid cells—or from the attic; (3) reinfection from the Eustachian tube or the external auditory canal—here there are temporary cures with frequent relapses.

(c) The nature of the infection—e.g., T.B.

When a microscopic examination is made of the discharge from a case of acute suppurative otitis media one variety of micro-organism is seen to be present alone or to greatly preponderate. In the chronic case, on the other hand, there is a mixture of many different organisms. It may be said that in the acute case the ear is "suffering from an infection," whereas in the chronic case the ear is "irritated by a confection." This constitutes what is called above "tympanic sepsis."

If a series of cases be examined and a diagnosis attempted as to the probable cause of chronicity in each it will be found that many may be ascribed to tympanic sepsis alone. This can be confirmed by treatment confined to the tympanum alone. Zinc ionisation is a method by which the tympanum can be disinfected without being irritated. In many cases no other treatment, or no repetition of the treatment, is necessary, and when the patient is seen again—next day, or in a week, or in a fortnight, as circumstances permit—the suppuration has entirely ceased and there is no sign of inflammation, the mucous membrane being pale and clean, and the remains of the drum not swollen or hyperæmic.

If it is observed at the time that the patient is treated that the mucous membrane is much swollen, or that some small granulations are present, it is advisable after ionising to insufflate a little boric acid to absorb any fluid exuded and to endeavour to keep it sterile.

Ninety-nine ears were recently treated. These cases were not selected, except in so far as only those were ionised which might be provisionally considered as owing their chronicity to tympanic sepsis alone. Most of the cases had already received treatment for a longer or shorter time by recognised applications.

The patients were instructed not to use any treatment at home and to be careful not to allow any water to enter the ear. The results may be classified thus:—

(a) Ears in which discharge ceased, 54.

Of these 5 relapsed: 2 due to causes undetermined, 1 to adenoids, 1 to cholesteatoma, 1 to Eustachian trouble.

(b) Ears of patients who did not return or are still under treatment, 25.

(c) Ears in which the discharge did not cease and in which it was discovered after ionisation that—

(1) Small polypi or granulations were present, 9;

(2) Attic disease, complete Eustachian obstruction, or some other complication existed, 8.

(d) Additional cases in which recovery may not have been due mainly to ionisation—e.g., to inflation, 3.

Zinc ionisation is useful for diagnostic purposes. If the discharge has not ceased after one treatment it is

usually easy to diagnose what is the reason, as swelling and inflammation have disappeared except at one place, or discharge is localised to one area. Where polypi have been dealt with subsequent ionisation will cure the discharge.

Three of the 54 cases used drops at home, two by mistake for a time, and the third had an incision into the drum where there was a tiny perforation and carbolic acid was applied to the margins; another had, besides ionisation, pure carbolic applied to a granulation. In the remainder treatment was only applied at the time of the patient's visit, and consisted in ionisation, with or without the insufflation of boric acid (or in a few cases of formidine) immediately after ionisation or subsequently if a little discharge was still present. 45 had one ionisation; 7 had two ionisations; 1 had three ionisations; 1 had four ionisations. The zinc ion was used in all. In two the salicyl ion was also used, and in two others the silver.

A few illustrative cases are submitted.

(A) Patient states duration of discharge.
(B) Diagnosed cause of chronicity.

T.s., tympanic sepsis. * Pockets due to adherent drum. † With polypoid condition of mucous membrane on inner wall. ‡ ? aditus. ? attic, meatus inflamed.

All the visits and treatment from the time ionisation was given till the discharge ceased are mentioned.

It is not yet possible to estimate exactly what is the proportion of patients suffering from chronic otorrhoea attending the special department of a general hospital in which it may be expected that cure will rapidly follow ionisation. I know it is large.

In conclusion, I wish to express my best thanks to Mr. Gay French, of the Royal Free Hospital, and to Sir James Dundas Grant of the Aural Clinic, Ministry of Pensions, for the facilities which they have freely granted me to treat patients. I am greatly indebted to them.

SOME OBSERVATIONS ON THE TREATMENT OF GONORRHOEA WITH DETOXICATED VACCINE.

BY W. V. CORBETT, M.R.C.S. ENG.,
CAPTAIN, R.A.M.C., I/C GONORRHOEA BLOCK, ROCHESTER ROW, S.W.1;
AND

T. E. OSMOND, M.B. CANTAB.,
CAPTAIN, R.A.M.C., I/C LABORATORY, ROCHESTER ROW, S.W.

IN the following series of cases the clinical work and treatment has been carried out by W. V. C. and the preparation of the vaccine and the performance of the complement-deviation tests by T. E. O. The vaccine was prepared according to the method described by Captain D. Thomson, R.A.M.C., in THE LANCET of June 28th, 1919, and the complement-deviation tests performed on the lines laid down in the Medical Research Committee's Special Report Series, No. 19.

At the outset we decided that it would be of interest to take a series of cases and treat them with detoxicated vaccine in order to judge its effect upon them both "clinically" and serologically. At the same time a series of "controls" was commenced, these cases receiving no vaccine. The cases will be referred to as "test" and "control" cases respectively, and the abbreviation C.D.T. will be employed for "complement-deviation test."

Method.

With this end in view all cases which were admitted to the hospital suffering with acute gonorrhoea, and in whose urethral smears gonococci were present, were placed in one or the other series. All cases were submitted to treatment on the same general lines—i.e., irrigation of the anterior and posterior urethra with pot. permang. 1/12,000, increasing gradually to 1/4000 as the acute symptoms subsided. General treatment comprised a milk diet for the first four days, a minimum amount of exercise throughout, while medicinally alkaline mixtures, mist. alb., and belladonna suppositories were employed. Smears were taken on an average once a week, and urines were examined twice weekly.

Tests of Cure.

1. "Dry" after a "hospital pass" granted for three days a week from 2 to 7.30 P.M.
2. Passage of straight sounds.
3. Examination of first and second urines, and urine after prostatic massage, both macro- and microscopically.
4. Observation of the patient for an average of 28 days after he showed no further urethral discharge, during which period he was doing fatigues and physical training (half an hour twice daily).

Special Treatment.

The 123 "test" cases received detoxicated vaccine commencing on the day of admission. The first 18 of these "test" cases received a total of 40,000 millions spread over a period of 30 days, but for reasons to be stated later this was given up and the remaining 105 received a total of 60,000 millions given as follows:—

Dosage.			Dosage.		
1st day ...	5,000 millions		20th day ...	10,000 millions	
5th " ...	5,000 "		25th " ...	10,000 "	
10th " ...	7,500 "		30th " ...	15,000 "	
15th " ...	7,500 "				

The vaccine was given subcutaneously alternately into either arm. The 64 "control" cases received no vaccine.

Results.

Table I. shows the results obtained, and Table II. is an analysis of the "test" cases.

TABLE I.

(A) Average duration of disease in days before commencement of treatment.
(B) Average number of days to disappearance of discharge (includes relapses and duration of relapses, if any).
(C) Number of cases developing complications.

Class of case.	Total No. of cases.	(A)	(B)	(C)	Per cent. Relapses.	Per cent.
Test ...	123	4.2	38.5	6	4.9	11
Control... ..	64	3.5	48.4	10	15.6	3

TABLE II.
(A), (B), (C) as in Table I.

Test cases.	Total No. of cases.	(A)	(B)	(C)	Per cent.	Relapses.	Per cent.
Uncomplicated	93	2'9	41'3	6	6'5	10	10'8
Admitted with complications.	17	10'9	35'6	—	—	—	—
Admitted as "relapses."	13	5'5	22'0	—	—	1	7'7

It will be seen that the average duration of the disease including relapses of cases treated with "detoxicated" vaccine (test cases) is 38'5 days, as compared with 48'4 days for cases receiving no vaccine (control cases), but otherwise under identical conditions.

As regards complications, of 93 "test" cases 6 developed complications (5 epididymitis and 1 arthritis) = 6'5 per cent., whereas of the 64 control cases 10 developed complications = 15'6 per cent. On the other hand, of the 123 test cases 11 relapsed = 8'9 per cent. against 3 relapses = 4'7 per cent. of the 64 controls.

We should like to point out, however, that of the 123 test cases the first 18 were treated with only a total of 40,000 millions detoxicated vaccine (initial dose 2500 millions), and these 18 cases were responsible for 4 relapses. (It was for this reason that the remainder received the larger doses of detoxicated vaccine.) Another point worthy of note is that in calculating the days of duration of the disease the period of relapses is included; this therefore increases the significance of the shortened period of the disease.

It was noted by one of us (W. V. C.) that "test" cases admitted with or developing complications during treatment ran a milder course than those not treated with detoxicated vaccine. Only 1 case of the 123 cases showed any marked local reaction, and no uncomplicated case showed any local or general reaction. Complicated cases varied in the intensity of the reaction, two cases of arthritis complained of slight transient increase of pain in the joints, one epididymitis case complained of great pain in the testicle and his temperature went up to 103° F.; other epididymitis cases complained of a varying amount of increase in pain in the testicle; in none of these cases was the vaccine treatment stopped, and in all cases good progress was made; in every case where any reaction occurred it did so within 24 hours. A large majority of these cases showed a very marked improvement in the urethral discharge between the fourth and fifth dose of vaccine, and some cases became "dry" at this period in an almost dramatic fashion.

Complement-deviation tests were performed (by T. E. O.) within seven days of the completion of the vaccine course on 121 of the 123 test cases, with the following results:—

Total cases 121 } C.D.T. 64 showed a negative result.
 " 57 " positive "

In 20 of these cases C.D.T.'s were done before the first, after the fourth, and after the seventh dose of vaccine. This showed:—

At } 20 neg. After 4th } 11 neg. After 7th } 8 neg.
start } Nil pos. vaccine } 12 pos. vaccine } 12 pos.

The reason for doing a C.D.T. after the fourth vaccine was to ascertain whether there was any relationship between the clinical improvement at this period and the fixation of the complement. Of 25 control cases in which the test was done 17 showed a negative and 8 a positive result at the time of presumptive cure.

A further analysis of 121 "test" cases showed that in the 64 cases in which the result was negative at the end of treatment the average duration of the disease was 38'9 days, and in the 57 cases in which the result was positive at the end of treatment the average duration of the disease was 38'7 days.

Conclusion.

In conclusion, we would like to state that we realise that the number of cases taken is too small for any really reliable deduction as to the value of detoxicated vaccine to be drawn, still in view of the fact that cases

have been taken serially and not picked, and that test cases and controls were treated on exactly parallel lines, and that all were submitted to a long period of observation, it is noteworthy that the average duration of the disease in test cases was 38'5 days as compared with 48'4 days of controls—a decrease of nearly 10 days per case.

All through the period of the tests, which has extended over a year, we have tried to keep a perfectly open mind, and no calculations contained herein were made until the series was closed. Our thanks are due to Major C. F. White, O.B.E., R.A.M.C. O/C, Military Hospital, Rochester-row, S.W., for permitting us to make this investigation and allowing us to publish the results.

HERPES AND CHICKEN-POX.

By CLAUDE B. KER, M.D., F.R.C.P. EDIN.,

MEDICAL SUPERINTENDENT, EDINBURGH CITY HOSPITAL; LECTURER ON INFECTIOUS DISEASES, EDINBURGH UNIVERSITY.

A CONSIDERABLE amount of interest has been taken recently in the question of the alleged relationship of herpes and chicken-pox. Although at first sight it may appear extremely improbable that there is in reality any connexion between two conditions which we have been accustomed to regard as entirely separate entities, and which in the vast majority of instances present only very superficial resemblances, a study of recent literature will, I think, compel an unprejudiced reader to regard the question as one which deserves serious discussion. A few years ago I was quite content to assume that the interesting occurrences from time to time reported in the journals could be readily explained by coincidence. The coincidences, however, are getting sufficiently numerous to be somewhat puzzling; and a brief review of the whole subject may be not without interest.

Bokay,¹ in 1892, reported that he had seen nine cases in which chicken-pox appeared from eight to 20 days after an attack of herpes zoster had affected another person in the same family or hospital ward, and when the possibility of the chicken-pox having arisen from any other source apparently could be excluded. More recently numerous similar occurrences have been described by other observers, and Le Feuvre² in particular has stoutly maintained the theory of the identity of the two conditions, and has made an interesting collection of cases gathered from the literature.

Before discussing, however, the cases which have been reported up to date it may be well to consider whether by any possibility errors of diagnosis may account in some degree for the now acknowledged frequency with which one of these diseases follows the other. Are there, in the first place, abnormalities in the distribution of the eruption of chicken-pox which might tend to a diagnosis of herpes being arrived at; and secondly, can the herpetic eruption assume such a character that chicken-pox might reasonably be suspected? Both these questions can, I am inclined to think, be answered in the affirmative.

Abnormal Distributions of the Chicken-pox Eruption.

It is, of course, well known that in small-pox a concentration of the eruption may be determined by local pressure or irritation on any part of the body, and sometimes in areas where, under ordinary conditions, the pocks may confidently be expected to be sparsely scattered. Good examples of such concentrations are not infrequently observed after the application of a mustard leaf during the initial fever, and at the site of the collar stud, the bootlace, or the garter. It is, perhaps, not so well appreciated that the eruption of chicken-pox may be influenced in its distribution by similar causes, although the normal distribution in this disease is such that we would not naturally expect such abnormalities to occur nearly so frequently as in such a fever as small-pox, in which the distribution appears to be determined almost entirely by the comparative amount of exposure, friction, and irritation of the

different areas of the skin. Hamburger⁸ has suggested that some of the alleged cases of herpes zoster, which have been followed by chicken-pox, may have been in reality cases of chicken-pox itself with the eruption determined in its distribution by such a cause as the pressure and friction of badly fitting corsets. We see occasionally infants whose eruption is particularly profuse in the region covered by the napkin as the result of irritation by the excretions. I have had under my care a boy whose clavicle was fractured during the incubation period of chicken-pox, and who presented on the shoulder, arm, and chest on the affected side a spotting at least three or four times more profuse than on the other parts of the body, this distribution being due to the bandages. Another recent case, a young lady, who had very typical discrete chicken-pox lesions on the trunk, showed on the face such a copious and closely set eruption that she gave quite the impression of small-pox, especially as the brow and prominences of the face were much more affected than the less salient parts. This was easily explained by the fact that she had just returned from a week-end in the country, where she had spent her time sitting in the sun, and the irritation of the sunburn had determined the localisation of her eruptions. Similar cases have been reported by Gautier⁴ as occurring in children who were being treated by heliotherapy. Another patient of my own who developed his chicken-pox only four days after an intense scarlet fever rash had an unusually profuse eruption on the trunk and extremities, and yet had only two or three vesicles on the face. This suggested that, had not the fever occurred during the incubation period, he would probably have had a very scanty eruption, whereas the skin hyperæmia caused it to be very copious on the trunk and limbs, while the face, spared by the scarlet fever rash, presented, as it were, more resistance. It is noteworthy that in this patient the forearms were affected quite as much as the trunk, not a very usual occurrence in varicella.

I cannot say, however, that in any of these cases was the eruption grouped in a herpetic manner. It is nevertheless conceivable that cases might occur in which a concentration, determined by some unrecognised form of irritation, might suggest herpes to a not very careful observer. I do not lay stress on the probability of this, but its possibility is, none the less, worth noting. I have, on the other hand, seen two cases of undoubted chicken-pox in which the eruption, at first indistinguishable from herpes, became afterwards generally distributed over the body. As will be seen below, it might be possible to consider these cases as the concurrence of chicken-pox and herpes in the same individual, and Dr. Le Feuvre has, in a letter to myself, already claimed them as such. I am far from saying that he is not right, but in the meantime I prefer to put them on record merely as illustrating a possible anomaly in a chicken-pox eruption.

CASE 1.—A small girl developed what appeared to be an absolutely typical herpetic patch over the left shoulder-blade. Next day, however, a few outlying vesicles, one apparently typical of varicella, appeared in the neighbourhood of the patch, and one or two more on the right side of the back. There was nothing at any time below the waist-line and nothing on the face, scalp, or limbs. I sent her to a chicken-pox ward where she did not contract the disease, and, 17 days after her removal, one of the children who had been exposed to her developed chicken-pox.

CASE 2.—Another little girl, a few days after admission with diphtheria, developed an unusually copious herpetic eruption. The distribution on the first day was entirely limited to the area supplied by the posterior divisions of the dorsal spinal nerves, but was equally well marked on both sides along the spine. Next day there was one spot on the face, and herpetic groups above both elbows, limited apparently to the supply of the upper division of the external cutaneous branch of the musculo-spiral nerve. On the succeeding days, however, other vesicles much more typical of chicken-pox appeared on the flanks, chest, and abdomen, and two other children in her own home were reported as having developed ordinary chicken-pox on the day of her attack.

Generalisation of the Eruption of Herpes Zoster.

We must here assume that it is possible for herpes zoster to become "generalised"—that is to say, to develop outlying vesicles which may be distributed over the whole body. There is much to be said against such an assumption, particularly on anatomical grounds, but it is in any case necessary to refer to the

cases which have been described under this name, whether we ultimately decide to regard them as instances of herpes, of concurrent chicken-pox and herpes, or of chicken-pox alone. Parkes Weber⁵ has reported two interesting examples of this condition (one of which, it may be mentioned, was followed by chicken-pox in another individual), and has gathered from the literature some 20 references to it. He quotes, in particular, Minet and Leclercq,⁶ who collected 25 cases of generalised herpes and who state that the aberrant vesicles may appear simultaneously with the outbreak of the typical zoster or may develop from a few hours to a few days after it. The latter was the case with Parkes Weber's patients, in whom the generalised eruption did not manifest itself for five days after the zoster in one instance and at the end of the first week in the other. In these cases of so-called generalised herpes we find the aberrant vesicles described as resembling closely those of varicella. They seem to be less deeply seated than those of ordinary herpes, and than those of the original patches with which they seem to be connected, and heal more quickly and with less cicatrisation. In one of Le Feuvre's papers⁷ an account of nine cases collected from the literature is given, and there seems to be no doubt in his mind that the condition is one of herpes and chicken-pox combined, and depends upon an identical virus. If he is right, the two cases which I have reported above appear to be of the same nature. In both the chicken-pox was undoubted, and in both it followed within two days a condition originally diagnosed as herpes. I have seen, however, another case in which a definite diagnosis of chicken-pox could not be made, and which appears to conform more closely to what has been described as generalised herpes.

CASE 3.—A male of 55 years was sent into hospital as suspected small-pox. He reported that five days previously he had suffered from shivering and pain in the lower part of the back. He had also had some fever up to the time of admission. On examination I found a few dry vesicular lesions on the scalp and one or two on the face. There were several on the trunk, of which one or two were well filled and somewhat varicella-like in appearance, while others were dry and crusted. In particular, there was one very suggestive oval crust on the right shoulder-blade. Only one vesicle was observed below the elbows, and the legs were free of any spotting. Round the anus on the left side was a profuse eruption of typical herpes with some outlying vesicles, which were identical in appearance with one or two noticed in the sacral region. On the following day fresh herpetic groups were apparently struggling to come out on the inside of the upper part of the left thigh, and a small herpetic patch was observed on the left side of the scrotum.

If we are to regard this case as one of generalised herpes it may be noted that the eruptions, whether herpetic or varicella-like, appeared probably simultaneously. The pain in the back which caused the suspicion of small-pox was undoubtedly due to the fact that the sacral nerves were those chiefly affected by the herpes. I am far from convinced that the scattered vesicles and crusts were actually those of chicken-pox. There was no history that the patient had previously suffered from that infection, but he could not state with any certainty that he had not had it.

Association of Chicken-pox with Herpes.

Le Feuvre, who has done much to stimulate interest in this question, was able in 1917 to collect 50 examples of herpes preceding, following, or coexisting with chicken-pox. Since that date several other instances of this curious association have been from time to time reported.

A. *Cases of herpes zoster followed by chicken-pox.*—It is into this group that most of the cases reported in the literature fall. A case of shingles occurs, and after an interval, approximating to the ordinary limits of the incubation period of chicken-pox, a contact, usually a member of the same family, develops varicella. Out of Le Feuvre's 50 cases no less than 41 are of this type, and seven of these were observed by himself. In a paper of a later date he has added two more. In every instance the interval elapsing before the appearance of the chicken-pox fell between the limits of 12 to 21 days. To the papers of Le Feuvre and to that of Parkes Weber full lists of references to the literature are appended, and I will content myself here with the mention of more recent observations.

Cranston Low⁸ has reported two cases, Taylor⁹ four, and Charpentier,¹⁰ Dingwall Fordyce,¹¹ and C. Wilson¹² one each.

I take this opportunity of putting on record four cases of my own.

CASE 4.—On Dec. 23rd, 1918, a child suffering from whooping-cough developed a typical herpes zoster with no outlying vesicles. On Jan. 7th a child in the same ward was discharged from hospital and developed chicken-pox within a week of her return home. The date on which the first vesicle appeared was not ascertained, but it was quite clear that the onset of the eruption was within 21 days of the appearance of the herpes in the other patient. A few presumably unprotected children, however, who remained in the same ward escaped infection.

CASE 5.—A girl of 8, suffering from scarlet fever, developed a typical herpes zoster on Sept. 23rd, 1919. On Oct. 11th, 18 days later, two children, aged 5 and 6 years, whose beds adjoined that of the herpes patient, presented a characteristic chicken-pox eruption, and on the following day a third child, aged 9, who occupied the bed exactly opposite, also developed chicken-pox.

CASE 6.—In the same year, 1919, a scarlet fever patient in another ward had a typical attack of herpes zoster. This was followed 25 days later by an outbreak of chicken-pox affecting several children. As the herpes case was not removed from the ward, this long interval does not exclude a possible incubation period, as, if the infection was really derived from the herpes, it need not necessarily have been contracted during the first three or four days of that condition.

CASE 7.—In 1918 a child was admitted with chicken-pox from Dr. J. S. Fowler's wards in the Royal Hospital for Sick Children. There had been no obvious source of infection, but a case of herpes zoster had occurred in the ward 19 days previously.

It must be understood that in all these cases any more natural source of infection was, so far as possible, excluded. As regards two of my own, in particular, it may be noted that they occurred in convalescent scarlet fever wards. Now, with a view of keeping these wards quite free from secondary infections, no patient is transferred to them before he has been at least three weeks in hospital and has therefore terminated the period during which any infection contracted before admission is likely to develop. As a result, with the exception of post scarlatinal diphtheria which is due to undetected carriers, it is most unusual for secondary infections to occur in convalescent wards, and it is remarkable that, on two of the rare occasions on which chicken-pox has made its appearance there, herpes should have preceded it. Nevertheless we cannot entirely exclude the possibility of "missed" cases of chicken-pox having been responsible for infection in these cases, or, indeed, in the other cases, reported in the literature.

The cases in this group, including those of Le Feuvre, those quoted above, and my own additions, amount to 56 in all. No doubt there are others in the literature which I have missed.

B. *Cases of chicken-pox followed by herpes.*—It appears to be much more unusual for herpes to follow chicken-pox within the limits of a possible incubation period, but none the less such cases have been reported. Le Feuvre collected five in his original series, and in a later communication added one more. I am unable to make any addition to this number, neither having had such an experience myself nor having been able to find in the literature since 1917 accounts of similar occurrences. The number of them, indeed, appears to be so small that the theory of coincidence does not, so far as this particular group of cases is concerned, seem to present any difficulty.

C. *Cases of herpes and chicken-pox in the same individual at the same time.*—It has been mentioned above that the two cases (Cases 1 and 2), which I have preferred to describe as examples of chicken-pox starting with a herpetic distribution, might be regarded as instances of this combination, and it will be admitted that generalised herpes may account for some of the cases reported, especially if they are not followed, as was one of Parkes Weber's, by an outbreak of chicken-pox after a suitable interval. Thus the rash, "indistinguishable from varicella," which appeared a week after the onset of characteristic dorsal and lumbar herpes, recently described by Downes,¹³ might well have been generalised herpes, and, as the children of the family had never had chicken-pox and did not contract it, this presumption is to some extent strengthened. Le Feuvre includes 4 cases in his series of 50 which he is satisfied were in reality instances of herpes followed in the same individual by chicken-pox

within a few days—that is, two days to a week. I have not noticed any others in the recent literature. Dr. D. W. Scotland, of Colinton, has told me that one of his patients, a lady of 50 years, developed a severe attack of chicken-pox a fortnight after the onset of lumbar herpes. The interval here is much longer than has been usually noticed, and we can hardly explain such a case either on the theory of a generalised herpes or of a chicken-pox with an originally herpetic distribution. Although no source of infection was detected and the coincidence is a very curious one, it seems not improbable that there was no real connexion between the two attacks.

D. *Cases of chicken-pox and herpes appearing simultaneously in different individuals.*—Cranston Low⁸ reports that a patient in a ward of the Edinburgh Royal Infirmary developed a typical right-sided thoracic herpes zoster. Two days later a child in the same ward developed chicken-pox. Both these patients had been in hospital several weeks, and it is suggested that the infection had been introduced by visitors. Oakes¹⁴ in 1913 reported that he saw two children in one household on the same day, one with typical shingles, the other with typical chicken-pox. Gray¹⁵ has put on record a similar occurrence. Three brothers were admitted to hospital with scarlet fever. The eldest, who had no previous history of chicken-pox, had well-marked right-sided herpes zoster, and had one or two spots on the left side of the chest which, on healing, left scars suggestive of chicken-pox. Four days later one of the brothers developed chicken-pox, which the younger child took from him after the usual incubation. Unfortunately it is not stated whether the herpes had been long present before admission or had only just appeared, but if the latter, the case appears to fall into this group.

Epidemic herpes.—It is interesting to note that, in addition to the curious association of the two conditions as exemplified above, there is some evidence that herpes occasionally appears in what might be described as an epidemic form; that it is unusually prevalent, for instance, in a particular place at a particular time. This, of course, might mean nothing more than that it is influenced by climatic conditions, of which as yet we know nothing. Further, it has been reported as being epidemic along with an epidemic of chicken-pox. Heim¹⁶ has recorded such an occurrence in 1912 at Budapest.

Theory of the Identity of the Virus.

It is on such facts as have been collected above that some observers have come to the conclusion that the virus of herpes and chicken-pox is one and the same. This view is strongly held, both by Le Feuvre and Cranston Low. The latter has advanced the ingenious theory that in herpes the infection is local, through the nose and along the lymphatics round the olfactory nerves, as has been shown to be the case in anterior poliomyelitis, whereas in chicken-pox there is a blood infection with the virus. In the combined cases it is presumed that the infective agent reaches the spinal ganglia first, and a few days later invades the general circulation.

Difficulties in accepting the identity theory.—Admitting that it is not easy, in the light of the above facts, to exclude absolutely the possibility of a real relationship between the two conditions, much yet remains to be explained. The question of immunity, for instance, requires careful consideration. Many patients who suffer from herpes have undoubtedly had chicken-pox previously, and there is no reason to believe that herpes confers any protection against chicken-pox. For example, Savill¹⁷ mentions an instance of a boy developing herpes five months after an attack of chicken-pox, and Dr. Scotland's case, mentioned above, shows that chicken-pox can follow closely upon herpes. Are we to assume that the general blood infection is not sufficient to make the individual immune to the local nerve infection and vice versa? Moreover, herpes does not protect against itself, second attacks being known to occur. J. Taylor⁹ has recently reported instances of such second attacks. Cranston Low doubts if such recurrences are genuine herpes, and attributes them

to the irritation of recurrent attacks of peripheral neuritis, but, after all, as second attacks appear to be rare, the mere fact of their existence is no real argument against the infectivity of herpes, as they occur occasionally in all the infectious diseases. But, from another point of view, herpes does not behave as if it depended on a living virus. The frequency with which it has been reported to appear during a course of treatment with arsenic is very difficult to explain on any theory of infection. Le Feuvre seems inclined to brush this difficulty aside and seriously to consider the possibility of an infectious disease arising *de novo* under suitable conditions, a line of argument in which I am not prepared to follow him. Otherwise it must be assumed that arsenic renders the individual especially susceptible to infection, and that the possibilities of such infection are much more frequent than can easily be imagined.

Discussion.

Looking at the subject as a whole it seems not unfair to conclude that the small number of cases in the second group—that is to say, chicken-pox followed by herpes—may readily be explained by coincidence. Further instances of this sequence certainly should be reported before we can lay much stress on it. Secondly, the cases in the third group, that of the two conditions co-existing, may be accounted for either by chicken-pox starting for some unknown reason with a herpetic distribution, or by the phenomenon known as “generalised herpes.” Some, it is true, may question the possibility of herpes becoming generalised, though, if we grant that herpes depends upon a virus, there is no particular reason why that virus should not occasionally be diffused through the nervous system much as that of anterior poliomyelitis appears to be in certain instances. On the other hand, the two conditions may coexist in this group of cases quite fortuitously, though the regularity with which, in the cases reported, the general eruption has followed the local one within a week, suggests that there is a definite connexion between the two. The fourth group, again, simultaneous attacks of herpes and chicken-pox in different individuals, might well, from the small number of cases recorded up to date, depend upon coincidence. So far, then, as these three groups are concerned, the case in favour of an identical virus does not appear to be a strong one, though they assume an undoubted significance as long as the occurrences in the first group remain unexplained.

It is, in fact, the first group for which it is difficult to supply an adequate explanation. A large number of instances have been reported in which chicken-pox has followed herpes in another individual, and always within the limits of the incubation period of the former disease. If chicken-pox appeared as commonly two months after herpes as it does within three or four weeks, I cannot doubt that that fact would have been put on record, and it is this occurrence of an apparent incubation period which compels most attention and which cannot be put lightly aside. We probably all have a prejudice in favour of keeping what we consider different diseases in watertight compartments, as it were, but, after all, we know singularly little about them, and it is quite possible that the same virus may behave quite differently under different conditions. As it is, the fundamental identity of diseases as different in their symptomatology as influenza, anterior poliomyelitis, encephalitis lethargica, and cerebro-spinal fever has been seriously suggested and discussed, and although I am far from accepting such a view, particularly as regards cerebro-spinal fever, it is obvious that the same poison acting on different structures might be expected to cause different symptoms.

The key to the mystery lies, I am convinced, in the hands of the general practitioner. All cases in which any association of the two diseases is noticed should be carefully noted and put on record. What I think is equally important is to keep a note of all cases of herpes which, occurring in a family where there are susceptible children, are *not* followed by chicken-pox. For instance, in the last four years seven cases of herpes

zoster have occurred in the Edinburgh City Hospital in wards in which there were one or more children who had not previously suffered from chicken-pox. Three of these cases have been followed by outbreaks of chicken-pox otherwise unexplained. It must again be repeated that the possibility of a missed case of chicken-pox being the real cause can never be entirely excluded, especially when one remembers that the whole eruption of that disease may be represented by one spot and in consequence very easily overlooked. A series of similar observations, however, would give us some idea what percentage of cases of herpes are followed by chicken-pox, and should such a percentage be found to be considerable the relationship between the two conditions might be more reasonably accepted. The proportions, moreover, of herpes patients who have or have not previously suffered from chicken-pox would be an interesting addition to our knowledge. Attention might also be given to the question of second attacks of herpes and to the dates on which herpes occurred in the practices of the observer and his neighbours with a view to investigating epidemicity. All that is required is a certain number of practitioners—say one hundred—willing to note such facts for a period of three or four years. Still more light would be thrown on the subject if a few medical officers of health would persuade their local authorities to follow the example of Bulawayo, which, no doubt at the instance of Dr. Le Feuvre, has made both “shingles” and “chicken-pox” notifiable diseases. But until a considerable mass of information can be obtained we must, I fear, leave the question an open one, recognising at the same time that such information is necessary before we can, with any justice, absolutely repudiate the theory of identity.

THE ANALYSIS OF A FUGUE.

By R. L. GAMLEN, M.A., M.D. CANTAB.,

CAPTAIN, I.M.S. (RETIRED); SENIOR MEDICAL OFFICER, BRINNINGTON NEUROLOGICAL HOSPITAL, STOCKPORT.

THE following case may be of sufficient interest to warrant publication, inasmuch as the events which led to the final dissociation reveal themselves in well-ordered sequence.

X.Y.Z., aged 43, single, joiner, a native of East Anglia, who had lived in Manchester for some eight years, was admitted to this hospital on June 9th, 1920, with a history of having unaccountably left his home in Manchester on the previous Whit Sunday morning, May 23rd. His friends heard nothing of him till Thursday, May 27th, when the police reported that he was in a certain workhouse infirmary some miles from his home. He had been picked up in an exhausted condition the previous (Wednesday) midnight unable to give an account of himself and was taken to the infirmary. There he could not give his name, address, or occupation, and his mind was an absolute blank for all events in his past life prior to the previous Tuesday morning (May 25th), when he woke up to find himself in a strange park, except that he spontaneously recalled air raids in France. Other events of his army life were as completely forgotten as his civilian career.

A tram ticket from Liverpool to St. Helens which was found on him aroused no associations, and he was eventually identified as the result of a telegram sent from St. Helens on Whit Monday to his fiancée, telling her not to worry, that his head was bad, and that he would soon be home. This enabled the police to trace him.

Apart from the memory of air raids, the only link with his past which was revived in the infirmary was due to the policeman who took him there. This officer, himself from the Eastern Counties, recognised the patient’s accent, and this aroused some nebulous associations in the latter’s

mind, but not sufficient to enable him to say where his old home had been. On Saturday, May 29th, his fiancée, accompanied by a friend well known to him, arrived at the infirmary to take him back to Manchester. He did not recognise either of them, and Manchester, including the house and friends with whom he had lived for years, was entirely new to him. He astonished his landlord by asking where he could wash, receiving a reply more curt than courteous. Similarly a friend from his old home, who arrived a few days later in response to a telegram, was unrecognised, though a photo of the latter's young daughter aroused some unsystematised associations. The same photo portrayed the patient's nephew, whom he had seen as recently as last year, but he did not recognise the boy at all.

Condition on Admission to Hospital.

Z. continued in this condition until his admission here on June 9th. He was taken to a medical board on June 3rd, passing streets formerly familiar but now entirely strange to him: at the board the note was made, "Remembers bombing at Etaples and very little else." He accepted the statements of his friends as to former occurrences, his engagement, &c. (his fiancée obviously resembling a photo which he had in his possession), so that he was able to give an incomplete account of much of his past life. This knowledge, however, was not a recall of past impressions, but was, to him, new matter which he had learnt since his return to Manchester on May 29th.

The events narrated lacked the tang of reality for him, and he was still quite ignorant of the occurrences which had transpired unknown to his friends; for example, the happenings of Whit Sunday and Monday. His fiancée told him that on the Saturday preceding Whit Sunday he had been to B—l with her in the afternoon; he could not recall this, even after being told about it. Similarly, his joiner's shop was examined by his friends, and a bag of valuable tools, which he was accustomed to take out with him when working, was missing; he did not know of the existence of his shop and still less where the tools were. Again his friends told him that on the Whit Sunday morning he was going to fetch a new suit of clothes from his tailor's private residence. He had no idea of the tailor's name or address, or that he was getting a new suit at all. (It subsequently transpired that it was a newly opened shop where Z. had never dealt before, and his friends did not know of it.) A more serious matter was that he had securities deposited somewhere representing a large sum of money; he had no recollection of owning the securities or of where they were. His fiancée knew of them, but he had never told her where they were deposited.

As opposed to the amnesia for his past life, including the first two days of the fugue, his memory for events since he woke up in the park on Whit Tuesday morning, May 25th, was perfect, but it was a new existence sharply and absolutely demarcated from the former one. To recapitulate, therefore, apart from memories of bombing, he had amnesia for practically everything up to the morning of May 25th, except what he had re-learned about himself during his stay in Manchester between his return on May 29th and his admission here on June 9th, while he remembered everything that had transpired since May 25th, but could not link up these later events with anything that had happened previously.

It was at once evident that this was a perfectly genuine case and not the aftermath of a Whitsun spree. Z. was a most respectable and well-conducted man, a lifelong abstainer, whose previous career could be vouched for by responsible witnesses. It may also be stated that subsequent hypnosis confirmed that he had drunk nothing stronger than minerals during his wanderings. The past history was incomplete at this stage and will be considered later, but an arresting fact came to light at the first interview. On Whit Sunday, 1918, a fine and hot day, he had been through a severe air raid at Etaples, subsequently being taken for safety to a wood near a railway some kilos away, and on an equally fine and hot Whit Sunday two years later he had wandered from his home, "waking up" two days later by a railway bridge in a wooded park in Lancashire.

Hypnosis of Patient.

Owing to unavoidable circumstances it was not possible to give Z. much attention for a few days, and as, curiously enough, the sergeant who had drilled him as a recruit in 1917 happened to occupy the next bed—though Z. did not at first recognise him—the two men were sent about together to endeavour to recover the lost memories. This succeeded to a limited extent,

but the revived memories were confined to the period of their training together at Scarborough, and were probably, to some extent at least, "suggested" by the sergeant. As soon as opportunity offered, therefore (June 21st), I decided to hypnotise the patient. The commencement of the amnesia was vague and affected occurrences of years ago, so the first hypnosis was primarily devoted to recalling the events of the Whit Sunday and Monday. Z. readily passed into deep hypnosis, and most of the dissociated memories of the fugue were recovered. In places the story was sketchy, and the suggestion was given¹ that he would afterwards dream of the events he had spoken of during hypnosis, that any gaps would be filled up, and that after the dream he would remember them all as having actually occurred in real life, and would write them out on waking. This he did, and next day brought the following account of his journeyings:—

The Patient's Story.

"I remember on Whit Sunday morning having a nasty headache and a feeling I must get right away. It was a very hot day. I remember getting on a car and going to Stockport; from there to H— G—, calling at a small shop for some sandwiches and biscuits. The people were just coming out of church. I then walked through some fields by this church to some woods near B—l, where I remained nearly all the day. I remember the sun being very hot, and my head still aching, with a desire to still wander on. I remember at the time I bought the biscuits, &c., I changed a ten-shilling note, and left in a wallet eight pounds. While in the wood I also remember coming out and going to a small house on the road and having some tea and bread-and-butter, which would be, I think, about 7 or 8. I then had a feeling I ought to be going home, but could not remember where I wanted to go, so kept on walking and wandering about till midnight, when I had a sleep in a barn, somewhere, I think, near A—m; it was a beautiful moonlight night when I awoke. I still went walking on across country till I came to a place called M— G—, and then into S—n, where I met some colliers going to work, which I think would be about 5 o'clock. I remember telling them I wanted to get to some big town, but I could not remember the name. They told me how to get to Liverpool by car, as I told them it was a long way I wanted to get to. I got on a car to Ath—n, where we had to change again. I remember getting off the car and seeing some children dressed in white. It came to my mind all of a sudden then; I had promised to go with my young lady to watch the procession at Manchester. I was then close to a small house where they sold mineral waters, teas, &c. There were two cycle motorists came up at the time. I can remember tearing a piece of paper out of the wallet I had and asked them if they would take a telegram to the nearest post-office for me as I was not feeling well. I remember giving them this and a shilling; they said they were going to St. Helens. I then went in a field close to and ate some sandwiches I had left and went to sleep, as I felt so tired. When I awoke my head was much worse; I did not remember anything about sending the telegram. I was still anxious to get to Liverpool. I got on a car to A—n, and from there to St. Helens, went into a refreshment-room and had a good breakfast, then got on a car to Knotty Ash, where we had to change again for Liverpool. Before resuming the journey I went in a small wood close to and lay down for a while, and then went on a car again which had on the front "Pier Head," which took me right into Liverpool. I then remember going to a station, and having a good wash, as I was very dirty and dusty. I wandered about Liverpool for some time, but could not recognise any place I wanted, so thought I would go back the same way I came. I got on the car back to St. Helens; it was getting very late. I tried to get some sleeping apartment for the night, but it was so late I could not get in anywhere, so I thought I would still go farther on nearing A—n. I saw a kind of park (Haydock) with a railway bridge which looked a nice place for a shelter. I remember going to sleep, but before doing so I remember seeing two or three men in the park.

I can remember nothing else till I woke up [on Whit Tuesday, May 25th] and thought I would get some breakfast and go back to S—n. I had about 9d. in my pocket, knew I should want more, put my hand in my pocket for my wallet to get out another note, but could not find it. I looked where I had slept but could see nothing of it. I then stayed in the park for some time till I saw a party of ladies and children; they came up to me and asked what was the matter. I remember telling them I was not well; they asked me to have some milk, which I had, also something to

¹ I am indebted for this useful hint to Dr. Hadfield's article in *Functional Nerve Disease*.

eat. Towards night, knowing I had no money, I started to walk again; it looked so much like rain, and being tired I saw a chapel on the road. At the back there was a little washhouse. I went and sat in there for a time and had a sleep, then started walking towards Ath—n.

Before coming to Ath—n I went in a park close to and sat there for some time thinking and wondering where I should go. I found some food that had been left by someone and ate it, then went on to the library at Ath—n and stayed there for some time, then wandered about feeling very bad till I was found in Market-street about 12 o'clock [midnight, 26th-27th] and taken to the police station. They gave me some milk and questioned me, but could remember nothing. They then took me the next morning to—Union. I remained there till my young lady and gentleman friend of mine came to fetch me [on May 29th], but could not recognise them, and went back with them by train to Manchester, but could remember nothing about the town, still having pains in my head."

The above statement accounts for the whole fugue, though, as before narrated, the events which transpired after he woke up in the park on the Tuesday morning to find his money gone had never left his memory. Z.'s story answers the question which naturally puzzled one at first, "If he on Monday sent the telegram to his fiancée, remembering her address, why had he not been able to return?" He definitely says that after sending it he went to sleep in the field and did not remember anything about the telegram when he awoke. Again, why did he on the Tuesday and Wednesday go back through the same towns he had passed through on Monday, since he had quite forgotten where he had been on the Monday? He told me that he "felt an impulse" to take that route, though he did not remember having traversed it previously. Thirdly, why did he "wake up" on the Tuesday morning so that subsequent events were remembered? His own theory, when questioned about it after his memory had returned, was that it was due to the shock of finding his money gone. It is more probable that on the corresponding morning in France in 1918 the danger of that particular series of air raids terminated, and this was subsequently confirmed by his recollection of that time and also by independent evidence. There seems little doubt that the men seen in the park late on Monday night took his money. He remembered noticing that they were a rough lot, but in his state of absolute exhaustion he went to sleep and remembered nothing till morning. It is possible that he fainted from exhaustion, for he had walked at least 25 miles on very little food since the Sunday morning, not including his wanderings all day about Liverpool. The comparatively large sum of money which he had with him represented the amount owing for the suit of clothes which he had arranged to fetch and pay for on the Sunday morning. It will be noticed that his objective was always among trees, and he finally came to a halt on the Monday night in a park near a railway bridge. He said that the combination of trees and railway gave him a sense of security. [Cf. his experience in France two years previously.]

By similar methods the memory of his past life was recovered and assimilated to consciousness, so that a complete history could be constructed. The missing tools were traced to a corporation parcels office where he had deposited them some weeks before Whitsun, and were recovered. Of the securities more anon.

History of Patient.

Z.'s family and personal history was good; no epilepsy or automatisms. Many years ago he had a bicycle accident, which rendered him unconscious but left no legacy of headaches or defective memory, and he was "as good a man as ever after it." Called up early in 1917, at the age of 40, he went to Etaples in August of that year and worked as a carpenter in an artisan company on hospital construction and similar work. All went well until he came in for an air raid at Easter, 1918, but the hostile planes did not come very near on that occasion. [At this point in the hypnotic recital patient shook and evinced other signs of emotion.] At Whitsuntide, 1918, there were very severe raids and the company's dining-hall was blown up, though, fortunately, it was empty at the time. In the early hours of Whit Sunday morning there was a very big raid, and patient was hit on the foot by a piece of shrapnel. He remembers going out of camp soon after to a small wood to find a safe place to sleep in, as he felt he dared not stay another night in

camp. He was brought back and told that no one could leave the camp "on their own," but that a party would be organised every night, for those who wished it, to walk out to a wood some kilos away. Here were two railway lines, and he was told that a railway bridge was a safe place or, better still, against an embankment. A few days later proper dug-outs were constructed, and there was no need to retire to the wood. Z. experienced several other raids, which were chiefly during the week-ends. (The dates were verified from a calendar which he was able to obtain from a friend who had been with him at Etaples; this proved his memory of the events of that period to be very accurate.) The significance of these dates in connexion with subsequent events will be presently apparent.

Z. was always very apprehensive of raids and used to go to a dug-out or cave even when others did not consider it necessary to do so, thus gaining the soubriquet of "The Dug-Out King." One night he was leaving the hut and had to be stopped from doing so by the other men, whom he had awakened. He was aware of the occurrence and was not somnambulating, but felt compelled to go. Even till Christmas, 1918, weeks after the armistice, he felt this nervousness and restlessness at night.

Condition After Demobilisation.

Finally, in March, 1919, he was demobilised. He paid a visit to his brother in East Anglia, returning to Manchester just before Easter, 1919, after which he started business as a joiner. He resided with his former friends and rented a shop for his work.

During the ensuing year he was far from well. Although anxious to work, he felt unable to do so efficiently. His friends noticed that he was always worse at week-ends, when he frequently had to put off excursions which he had arranged with his fiancée. He was depressed and anxious and suffered constantly with "terrible" (sic) headaches. His memory was very defective. He also had a sense of impending disaster and a feeling that he must get "right away," though he did not know from what, and he had an ill-defined apprehension, which he knew was unfounded, that he would have to return to France. He felt he was not doing his work satisfactorily and was worried because he did not think he would be justified in marrying. He used to sit brooding in his shop and would often go out into the country for a day, thinking it would do him good and also because on these occasions he had a claustrophobia for his shop. This conduct appeared unreasonable to him, as he was ignorant of the reason impelling him to make these excursions; consequently he was ashamed to speak of them to his friends. This in turn led to his fiancée thinking he was not quite straightforward with her, which added to his unhappiness. He was only too conscious that his friends were watching him, to them, inexplicable conduct, and he became thoroughly miserable. He told me that during this period he feared for his reason, and, though suicide was not actually contemplated, he often wished he had been killed in France and was out of it all.

In addition to his general malaise there were several occasions when he was definitely incapacitated and went to his doctor. The most noticeable attacks were at Easter, Whitsun, July, August, and October, 1919, Easter and the three weeks preceding Whitsun, 1920. During the last period he was unable to work and consequently did not need the cloak-roomed tools. He felt too poorly to fetch them.

The relationship between these illnesses and events in France are shown in the following table, in which the dates of raids are verified by his friend's calendar and his illnesses from his own and his friend's statements:—

	1918.	1919.	1920.
Easter:	Air raid.	Unwell, went to his doctor.	In bed on the Saturday.
Whitsun:	Air raid.	Not fit.	Fugue.
July:	Raids 1st, 3rd, 13th, 24th, 31st.	Felt ill and went to his doctor.	
August:	Raids 1st, 10th, 13th.	Ill at Bank holiday.	
October:	Raid on return from leave at Boulogne.	Went to his doctor.	

On one or two occasions he suddenly collapsed face downwards, and on being picked up after one such attack asked "if he were in France." The events of Easter, 1919, may be briefly referred to because of their connexion with the missing securities. It was very difficult to recover the memories of these; he thought he had hidden them somewhere, but the only places at his legitimate disposal were his one-roomed shop and the house where he lived, so the choice seemed limited. Hypnosis, however, revealed that he had a vague recollection of taking them into the country and leaving them somewhere, but it was only after repeated hypnotism that the story could be pieced together. On Easter Monday, 1919, after an early visit to his doctor, as he felt ill, he felt impelled to take the papers with him into the country and took train for this purpose. At the end of the train journey he felt he must get still further away, so he took a vacant

seat in a charabanc which was bound for an historical part of Derbyshire. He left the charabanc and after walking some way through a wood, deposited the box in an ivy covered niche, subsequently returning to Manchester by train. A few days previously his brother had advised him to be very careful of the papers; it is therefore not surprising that when he went into the country feeling, perhaps subconsciously, that his own safety required it, he should have taken the securities with him. After hiding the papers he intended to fetch them, but forgot where they were; he felt that they were safe, however, and was accordingly easy in his mind.

Repression of War Memories.

Z.'s attitude towards his war memories was one of determined repression. All unpleasant memories were deliberately kept out of mind during the day and he gave the anticipated account of constantly repeated dreams of bombs and raids, together with a certain wood. This wood constantly recurred in his dreams, and was evidently the one near Etaples. Corroboration of the nightmares was obtained from the son of the house, with whom Z. shared a bedroom. Z. also made the interesting statement that at the times when he felt most ill he, in accordance with his friends' advice, made particular efforts to "forget" all about France, with the result that he noticed that his sleep was even more than usually broken by dreams and his headaches were much intensified. He used to wake with a start when dozing off, in a cold sweat and with his heart beating tumultuously. All this is quite in accord with the observations frequently made of the effects of repression, but the spontaneity with which he volunteered the information was striking. The battle dreams were particularly in evidence during the three weeks preceding the fugue and whilst he was in the infirmary.

Prior to the fugue he does not appear to have had amnesia for his army experiences, though his friends told him that his accounts did not always tally. It never once occurred to him that his wish to get away into the country, where he always sought a wood, was in any way connected with his conduct in France, where, it will be recalled, he was marched out at night to the woods of (?) La Foll and then felt safe.

Progress of Case.

After the first hypnosis on June 21st progress was rapid. Up to this, four weeks after the fugue, his memory had shown but little signs of returning, and it would be interesting to speculate as to what the outcome would have been had he had no friends to discover him and bring him for treatment.

Hypnosis was employed solely to recover the lost memory; to have used it to suggest that he would have no more fugues, without explaining to him how his illness had come about, would have been quite unjustifiable. The journeys into the country were his only means of escape, however inadequate, from his intolerable situation, and to block this safety-valve without showing him a better way out of his troubles might have had disastrous results, possibly even suicide. It was gratifying to hear him spontaneously relate how the weight of impending and unknown disaster which had been with him for so long was now quite lifted from his mind, and that he was sleeping well with no disturbing dreams. He volunteered the statement that an aeroplane which was one day near the hospital did not frighten him at all. He commented on this to his companions, because on previous occasions since leaving the army the sight of an aeroplane had always made him tremulous and nervous, even though his reason told him his fears were unfounded.

Stages in the Case.

The stages which culminated in the fugue were, therefore, first, the air raids, which affected Z. more than his colleagues. It will be remembered that he made for a wood on his own responsibility before the order was given for the men to sleep out, and he associated a wood, especially near a railway bridge, with safety. Then there was the episode of his feeling impelled to leave the sleeping quarters when he was stopped by his friends. Though not an unconscious act, it marks a stage towards automatism, as did his various excursions from Manchester. The Easter Monday occurrence was important in this connexion, since he afterwards entirely forgot where he had put the papers, though he remembered and spoke of the day's excursion, and, in fact, planned to make it again with his

fiancée. The connexion between his malaise at weekends and the air raids is obvious, while "the fits" of falling suddenly on his face were repetitions of similar acts in France. The baleful influence of repression was throughout responsible for maintaining and intensifying his condition. At first he could remember all the events of his army life, later his friends told him the accounts did not tally, and finally the memories became completely dissociated. Possibly even half an hour of psychotherapy 15 months ago would have spared him most, if not all, the misery of the past year.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

A CASE OF THE

MYOCLONIC FORM OF ACUTE EPIDEMIC ENCEPHALITIS,

WITH RECOVERY.

By DOUGLAS McALPINE, M.B., CH.B. GLASG.

IN THE LANCET of July 17th three fatal cases of the myoclonic form of acute epidemic encephalitis were reported by Dr. Arthur W. M. Ellis. The following case may prove of interest on account of the mildness of the attack and recovery of the patient.

A. T., female, aged 25, dressmaker, was seen in the out-patient department of Maida Vale Hospital for Nervous Diseases on June 10th, 1920, with a complaint of general nervousness and depression, insomnia, difficulty in walking, and twitching in her muscles. About May 17th she had pain in the back of her right forearm; this continued until May 23rd, on which date she went for a bicycle ride into the country. The same evening she felt a "drawing pain" on the right side of her chest, not aggravated by respiration. On the 24th the chest pain was associated with tenderness. The pain continued until the 27th, when she then felt it right round her body just above the waist; this only remained for about 24 hours. From May 24th onwards she had felt depressed and tired and had not slept at all; she thought she was delirious at nights—the latter two statements her mother confirmed. Her bowels were not open between May 24th and June 3rd. About May 30th she first felt sudden muscular spasms in both legs, chiefly in the thigh and calf muscles; each spasm only lasted a second or so. A few days later she noticed them in her abdomen. With the onset of these spasms the pain in her right side became much better. On June 4th, whilst walking, her knees frequently gave way; this has continued since that date; she thinks it is due to the spasms. Her mother stated that she had been slightly drowsy during the daytime, but patient denied having felt drowsy. No history of vomiting, headache, diplopia, or difficulty in voiding urine.

Examination in out-patient department.—Patient looks pale with an anxious expression. She talks quickly and excitedly, but there is no speech defect. Eyes are bright and staring. She answers questions intelligently. As she stands her knees give way suddenly from time to time owing to sudden momentary contraction of the hamstrings, usually bilateral. On examining the abdomen in the recumbent position sudden shock-like contractions are seen involving the lower segments, chiefly the left, causing the umbilicus to be pulled downwards. The tone of the abdominal muscles is slightly increased. Reflexes are present in lower segments, but absent in upper. A fine irregular tremor is present in both legs on voluntary movement. The same shock-like contractions are present in certain muscle groups in the legs—especially frequent are those in the peroneal group of the right leg and in the posterior group of the left leg. The contractions are much shorter in duration though just as powerful as those in the abdomen.

Earlier in the same week, owing to the kindness of Dr. George Riddoch, I had an opportunity of seeing one of the three cases reported by Dr. Ellis, and the similarity between the movements in that case and the one I was examining was so striking that I felt sure that this was a case of a similar nature. She was admitted into Maida Vale Hospital on June 12th, under the care of Dr. Anthony Feiling.

Condition on admission and subsequent course.—June 13th: M.T. 98° F., P. 88, R. 20. Patient states that she is very depressed and has considerable difficulty in moving in bed. Seems less excitable than on June 10th; no drowsiness; no disorientation. Constipation marked, bowels not acting since June 10th. Insomnia still present. Pupils moderately dilated; slight inequality, left being larger than right. Unsustained lateral nystagmoid movements. No strabismus or diplopia. Pupils react to light and accommodation. No facial asymmetry or other cranial nerve palsies. Fine tremor in outstretched hands; no ataxia. No sensory disturbance.

All movements in arms weak and carried out with apparent difficulty. No myoclonic movements. In the abdomen these movements are less frequent than on June 10th, occurring 2-3 per minute; left lower segment mainly affected. No reflex response can be obtained in upper abdominal segments; those in the lower segments are markedly slow, closely resembling the myoclonic movements. A general stimulus to abdomen is sometimes followed after a short latent period by a myoclonic movement of lower abdominal segments. The legs show a slight general weakness, especially distally. Hypotonia is present. No myoclonic movements observed. Fibrillary twitchings are present intermittently on plantar and inner aspects of left foot. Reflexes present in both legs, but are less brisk than normal. Bilateral flexor plantar response. No sensory disturbance. Urine: No abnormality; no difficulty in micturition. Heart and lungs negative.

18th: T. 99°6', P. 120, R. 22. Still complains of general weakness and loss of appetite. Insomnia continues despite hypnotics. Semidelirious during nights of 14th and 15th, but not since. She has not felt any more twitchings in her legs. No sweating. Frontal headache since 14th. Morning temperature 15th, 99°8'. Evening temperature remains normal. Pulse ranges between 100 and 120. Myoclonic movements less frequent in abdomen and vary in amplitude. Cerebro-spinal fluid clear. Cell count 15 per c.cm.; protein content not estimated. Wassermann reaction negative.

22nd: M.T. 98°8', P. 100, R. 20. Feels slightly better; sleep has improved but little. Constipation still marked. This morning felt twitchings in her legs similar to previous ones. Since 18th there has been a morning rise of temperature to 99°4' or 99°6'. Normal temperature every evening. Pulse 92-112. Pupils still unequal. General hypotonia still marked. Myoclonic movements in abdomen, but none observed in legs. W.B.C. 7000. Differential count normal.

28th: M.T. 98°6', P. 92, R. 20. Patient looks and feels better, but is still weak. On 28th she began to have shooting pains intermittently down back of both legs, especially left; her legs constantly ache and she says she does not feel as if they belonged to her. No more twitchings in legs. Bowels more regular; sleeping better. Temperature has been normal since 22nd, except for a slight morning rise on 25th and 26th to 99°2'. Pulse-rate still increased. Pupils more nearly equal. No nystagmoid movements. Abdominal reflexes are now present in upper and lower segments, but less brisk on right side than on left; still abnormally prolonged. Shock-like contractions occasionally seen chiefly in upper segments. Reflexes in legs remain the same except that left knee-jerk is more brisk; no plantar response can be obtained in right foot; no sensory disturbance in arm or legs.

July 2nd: M.T. 98°6', P. 96, R. 20. Feels better. Reads and knits. No pains in legs for last two days, but still has aching sensation in

the cases published in this country and in France. The initial pain, the insomnia and delirium, the marked subjective sensation of prostration, the constipation, the shock-like contractions most marked in the abdomen, a low-grade fever, and tachycardia are symptoms in this case in close accord with those described as part of the myoclonic form of acute epidemic encephalitis.

The following points are of interest in contrasting this case with those reported by Dr. Ellis:—

1. The inequality of the pupils and the absence of marked dilatation.
2. The absence of vomiting, difficulty in urination, disturbance in speech, leucocytosis, and sweating.
3. The presence of general hypotonia; this was a well-marked feature in the cases reported by Lereboullet and Foucart.¹
4. The character of the abdominal reflexes.
5. The trophic changes in the feet and hands.

I am indebted to Dr. Feiling for permission to publish the case.

South Kensington, S.W.

A NEW METHOD IN RHINOPLASTY.

By GILBERT CHUBB, D.Sc., M.B.LOND., F.R.C.S.ENG.

ASSISTANT SURGEON, THROAT HOSPITAL, GOLDEN SQUARE;
AND PLASTIC SURGEON, QUEEN'S HOSPITAL FOR
FACIAL INJURIES, SIDCUP.

THE case described was a gunshot injury. The tip of the nose, the anterior part of the septum, and the whole of the columella had disappeared. The nasal bones were, however, intact, and the greater part of both alæ were present, lying flat upon the face. (Fig. 1.)

Photographs of Mr. Gilbert Chubb's case showing Re-formation of Nose by a Tubed Pedicle taken from the Chest Wall.

legs. No headache. Myoclonic movements less marked in abdomen. No rise in temperature since June 28th. Pulse still rapid.

9th: M.T. 98°4', P. 92, R. 22. Improving, less depressed. No pains. No muscular twitchings. Sleep is improving, but still restless at night. Pupils equal; no myoclonic movements observed in abdomen. Muscular power in arms and legs improving.

16th: M.T. 98°, P. 88, R. 20. Patient was up for half an hour in a chair on 12th and 13th, but felt shaky; also had pains down back of leg. Pulse quicker on 14th and 15th—i.e., 112 and 108—but pulse-rate was not observed to be more frequent than usual on returning to bed each day. For last 10 days skin of sole of feet has hardened and patchy desquamation is now taking place on her toes and on adjacent sides of distal phalanges in her hands. No myoclonic movements in abdomen observed—abdominal reflexes are present and equal in all segments but are still abnormal. In the legs reflexes are now normally brisk and both plantar response flexor in type.

19th: T. 98°4', P. 104, R. 20. Feels stronger, appetite improving, sleeping better. Still has occasional shooting pains in both thighs. Also aching sensation intermittently. She has not been up since 16th owing to increased pulse-rate, which ranges between 88 and 100, but which remains regular. The patient is still under treatment.

Remarks.

The mildness of the attack in this case is of especial interest as contrasted with the very high mortality of

At the first operation a transverse tubed pedicle was made on the left side of the chest, immediately below the breast. The parallel incisions for this had a concavity directed upwards in order to prevent undue tension upon the pedicle in tubing. At a subsequent operation a piece of cartilage taken from the junction of the sixth and seventh ribs was carefully shaped to correspond to a plasticine reconstruction of the patient's nose and inserted beneath the skin at one end of the pedicle. Deep mattress sutures were employed to prevent its subsequent displacement pending the formation of fibrous adhesions to the surrounding tissues. The other end of the pedicle was then attached to the left forearm (Fig. 2, in which also the cartilage can be clearly seen at the upper end of the pedicle). Several weeks were now allowed to elapse in order to secure an efficient collateral circulation in the pedicle from this new attachment. At the next operation the pedicle, together with the cartilage implant, was released from the chest and attached to the nose. (Fig. 3.) Figs. 5, 6, and 7 illustrate the preparation of the

¹ Lereboullet and Foucart: *Bullet. Mém. de la Soc. Méd. des Hôp. de Paris*, 1920, xxxvi., 391.

nose for this attachment. A mesial incision (Fig. 5) separated the remains of the alæ from one another, and allowed of their being raised from the face. In the view of the nasal cavity so obtained can be seen the anterior limit of the remains of the septum. (Fig. 6.) A flap of skin outlined by the circular incision, seen in Fig. 5, was then dissected up and turned down upon its lower border as a hinge. (Figs. 6 and 7A.) The cut edge of the skin and mucous membrane lining the alæ and nasal cavity was defined, and the lower edge and sides of the flap carefully sutured to it with horsehair. Fig. 7A shows this inversion

of the flap nearly completed. The result is to complete the lining of the newly reconstructed nasal cavity, and completely shut it off from the wound. The free cartilage-bearing end of the pedicle was then trimmed as seen in Fig. 7B, so as to present two tongues, one long, bearing the cartilage and trimmed to fit the raw area left by the inversion of the flap, into which it was stitched. The shorter tongue was stitched to the lower border of the inverted flap and the intranasal lining of the cut tips of the alæ. In this way no raw area was left in the nose, the latter remaining dry from the operation onwards, and all healing being by first intention.

A columella was then formed from the outer portion of the upper part of the pedicle. The incisions for this purpose were carried up in a concentric manner over the tips of the alæ, so as to allow of the turning in of the columella and at the same time to bring the alæ forward into a normal position. All stitches were left long and untied, and the parts unapproximated until the last stitch had been inserted, thus ensuring as careful an approximation of the cut edges in what would finally be inaccessible regions as elsewhere. All stitches after tying were left long and tied together in a tassel issuing from the nares in order to ensure their ultimate removal.

Fig. 4 shows the patient several months after the completion of the final operation. During this interval the nose had undergone no change, and was as firm and "springy" as the normal organ. The rotation of the skin flap, in order to line the nasal cavity, and thus ensure against subsequent scar contraction, and the tubing of the larger flap are surgical methods extensively employed at the Queen's Hospital for Facial Injuries. The implantation of the cartilage on the chest and its elevation to the face by means of a pedicle borne on the arm has several advantages over methods previously employed. There is a complete absence of scarring about the face, neck, or breast, absolute symmetry can be maintained throughout the surgical treatment, and finally, the skin and cartilage implant can be got into a satisfactory condition away from the face before there is any interference with the latter.

Reviews and Notices of Books.

L'ANESTHÉSIE LOCALE EN OPHTALMOLOGIE.

By Dr. DUVERGER, Professor of Ophthalmology at Strasbourg. Paris: Masson et Cie. 1920. Pp. 96. Fr.6.50

THIS little book will be found full of interest to the ophthalmic surgeon, and though all the views of the author may not receive general endorsement, there is no page which cannot be read with profit. With regard to the ordinary methods of cocaine anaesthesia there is little new to be said, but we note that for ordinary cataract operations the author prefers to rely on so strong a solution as 10 per cent., three instillations of which produce an insensibility that is complete. In the experience of most ophthalmic surgeons half this strength is sufficient for the purpose. The main interest and purpose of the book, however, is the description of the methods of deep injection for operations on inflamed eyes and for enucleation of the globe, as well as for operations on the lids and lacrymal sac. The solution employed for all these is novocaine, generally in a strength of 4 per cent. with a few drops of 1:1000 adrenalin added, of which 2 c.cm. are required to render the globe anaesthetic, or three if the eye is inflamed. The solution is injected deeply by means of a needle $3\frac{1}{2}$ cm. long—sufficient to ensure its reaching the region of the posterior pole of the eye and ophthalmic ganglion without any danger of pricking the optic nerve. As in inflamed eyes the conjunctiva is acutely sensitive it is recommended that this deep injection should be made through the skin of the lower lid and continued between the inferior and external rectus. The outer zone of conjunctiva, which has its nerve-supply not from the ciliary nerves but from the nerves of the lids, can then be rendered anaesthetic by a subconjunctival injection of the novocaine solution. Similar detailed directions are given for rendering the skin anaesthetic for plastic operations on the lids and for extirpation of the lacrymal sac. The section on anaesthesia for advancement operations is worthy of note. The author finds the usual method of cocaine instillation unsatisfactory, and arguing that the sensitive nerve-supply of the muscles is from the ocular branch of the nasal, recommends the same technique of deep anaesthesia as for enucleation of the globe, or alternatively injections in the neighbourhood of the muscle, which, however, are not so effective.

For rendering the whole orbit anaesthetic more difficult procedures are called for. For Krönlein's operation a method is recommended for anaesthetising the superior maxillary nerve by piercing the sphenomaxillary membrane and injecting the solution into the pterygo-maxillary fossa. The author believes that the contra-indications to his methods are almost negligible and that they are destined practically to banish general anaesthesia from ophthalmic surgery.

THE AFTER-TREATMENT OF SURGICAL PATIENTS.

First edition. By WILLARD BARTLETT, A.M., M.D., F.A.C.S., and Collaborators. London: Henry Kimpton. 1920. In two volumes. Illustrated. Pp. 1066. £3.

THOUGH, as the author remarks, the need of after-treatment is, in many instances, in inverse proportion to the quality of work done on the operating-table, there certainly remains a great deal that can usefully be written on this subject. The surgeon will have his own methods which his experience has proved satisfactory; the house surgeon is working under supervision and will never be out of reach of advice when he needs it; and neither the one nor the other will often refer to any book on after-treatment except in cases of special difficulty which have not responded to ordinary methods, or when treating cases of uncommon diseases or after unusual operations. Therefore if such a book as this is to be of any real assistance it must give precise descriptions of all measures which may be useful in the treatment of both common and uncommon complications that may arise after any operation, and

actual details of the case of patients after special operations.

The two volumes satisfy these requirements to a very large extent. The various measures of post-operative treatment recommended are the results of the practical experience of the various authors, and others from whom they quote; they are described in considerable detail, and for the most part very clearly. The first volume deals with general subjects, such as sleeplessness, bed-sores, post-operative feeding, exercise, and massage. The second volume treats of methods of after-treatment that may be necessary following operations upon the various organs. The illustrations are well chosen and fairly numerous. There is a useful index, and reference is easy.

COMMON DISEASES OF THE SKIN.

By DR. G. GORDON CAMPBELL. Lecturer on Dermatology and Pediatrics. New York: The Macmillan Company. 1920. Pp. 229. 21s.

Dr. Gordon Campbell has adopted a somewhat unusual method of dealing with skin diseases. He has written a volume of 229 pages on the common diseases of the skin, amongst which he includes 43 distinct conditions. They are dealt with in alphabetical order, and are very fully illustrated, whilst pathology is barely mentioned, and treatment dealt with in the briefest outline. The common disease, impetigo contagiosa, has no fewer than seven illustrations, four of which occupy a whole page each. Syphilis has 24 illustrations, 16 of which are whole-page plates.

From these examples the reader will realise that the object of the author is to show graphically the varieties of common skin maladies. In the majority of the illustrations this object is obtained, but in certain cases the student would be led astray. Pityriasis rosea has no fewer than four whole-page pictures, from none of which could a diagnosis be made apart from the letter-press. Sudamina and milium and several of the lichen planus and urticaria plates are equally unhelpful. In a book of this type fewer plates, all of an equally high standard, would better have served the student. The paragraphs on treatment, while brief and to the point, are of varying value. Psoriasis is summarily, acne and ringworm are fully, dealt with.

There is certainly need of a text-book conceived on Dr. Campbell's lines, but some modifications on the lines above indicated would appear to be advisable for a second edition.

MALARIA AT HOME AND ABROAD.

By S. P. JAMES, M.D., D.P.H. (Lieutenant-Colonel, I.M.S., retired). London: John Bale, Sons, and Danielsson, Ltd. 1920. Pp. 234. 25s.

In this work the aim of the author "to provide an elementary guide to medical men and administrators who may have to deal with malaria at home or abroad during peace or war" is amply fulfilled. In it will be found a comprehensive and lucid account, not only of malaria from the clinical point of view, but of the life-history of the malaria parasite, the differentiation and distribution of the more important varieties of mosquitoes, and the various methods by which the breeding of mosquitoes may be combated and the incidence of the disease lessened in the malarial regions. The introduction of malaria into England by carriers from war areas where the disease is prevalent, and its spread among the local population, are fully described, and it is of special interest that, in the course of a malaria survey in Kent, cases were found that could not reasonably be ascribed to an origin from military foci, and which were regarded by the author as probable examples of indigenous malaria. Attention is drawn to the frequency of latent infections, in some of which the earliest clinical manifestations had been delayed for a period of several months subsequent to demobilisation. Exception may perhaps be taken to the statement that the greater number of the Macedonian infections were with both benign and malignant tertian parasites; cases of double infection were doubtless common in Macedonia, but that they constituted anything approaching a

majority of the total number of cases is contrary to the impressions formed by those who were working on the spot. On the vexed question of quinine administration in blackwater fever the opinion of the author that, with parasites present in the blood at the beginning of an attack, quinine should be withheld, will not receive unanimous endorsement. The publication of this work at the present time is especially opportune. The subject-matter is well arranged and the text is supplemented by a large number of excellent illustrations and diagrams. The terse and graphic style of the author greatly adds to the interest of the book, which should be read by everyone concerned with malaria and its problems.

LECTURES ON INDUSTRIAL ADMINISTRATION.

Edited by B. MUSCIO. London: Sir I. Pitman and Sons, Ltd. 1920. Pp. 276. 6s.

THE science of medicine passed during the nineteenth century through a period of precision; life was looked upon as precise chemistry, none the less precise because complicated; pharmacy presented drugs to cure and remedy most variations from health; even the microbic origin of certain diseases only concentrated attention the more on the laboratory as the place to study diseases; materialism ruled, and the teaching of our great forefathers was almost neglected, that for health of body health of mind was necessary. From this stage we are now emerging, and no sign of the change is more pronounced than the increasing attention devoted to-day to psychology. We meet it at every turn. It has found a profitable field for expansion in the rapidly developing science of industrial health, where the social life and mental outlook of the worker is inseparably bound up with his health and sickness.

There has just been published a selection of lectures delivered at the Cambridge Psychological Laboratory dealing with industrial administration. Here we find meeting on common ground persons whose interests otherwise are as poles asunder—Professors Myers, Cullis, Sorley, Pear, Collis, Messrs. Wrong, Stelling, Burt, Wyatt, Fleming; philosophy, engineering, social economy, psychology, physiology, medicine, all are represented, each benefiting by contact with the other. Professor Sorley deals with ethical aspects of industry; he claims a man should give an equivalent for what he gets, and the employer "a fair day's wage for a fair day's work." And further aptly says: "It is good to feel tired sometimes, though it is not good to feel tired all the time. Nothing great has been accomplished without toil." Mr. E. M. Wrong discusses some tendencies in industry, and claims that industry must discover some more satisfactory method of responsible government than at present exists. Management must become a learned profession; and managers must recognise their duty is to deal with the psychology of men, rather than the physics of materials. Expert advisers, engineers, and chemists should deal with technical problems. Managers to-day are over-busy with many things and do not study labour enough or carry out scientific observations upon the human material they have to control. Mr. A. R. Stelling explains the principles introduced by Dr. Frederick Taylor, and points out how failure has followed part adoption of these principles, with omission usually of those which concern the psychology of the workers. The impersonal factors are adopted, the personal neglected. The right way to follow out motion study is explained, and the necessity for humanity in works management is pointed out. Mr. Stelling holds that Taylor's theories are practicable in this country, providing a complete solution of the problem of the increase of production. Mr. Cyril Burt treats of vocational selection of workers, an entrancing and comparatively new subject in which mental and physical attributes come together for study. Here individual psychology, "the youngest branch of the youngest of the sciences," is invaluable. Vocational selection not only pays, but is a measure of social justice. This lecture is one of the best in the volume. Mr. Wyatt deals with an interesting side line, the psychology of advertising.

The reader after perusing it will ever after pay more attention to the advertisement-covered hoardings. Professor T. H. Pear carries us into the realm of abstract psychology, and we frankly confess the expedition does not grant much knowledge for practical daily use.

A discussion of industrial overstrain and unrest by C. S. Myers, on the other hand, though at times abstruse, will appeal more to our profession. He deals particularly with fatigue, and claims that "the pathological expression of fatigue—i.e., overstrain—is far less prevalent in muscular than in mental exertion." He puts in a plea for an organised whole-time industrial medical service of physicians specially trained after graduation, comparable to that in existence for the maintenance of public health; and for the establishment of industrial clinics and sanatoriums. Professor Winifred Cullis writes on women in industry, a subject peculiarly her own; hard work should not if under good conditions exert a harmful effect upon a woman, nor will it interfere with the function of child-bearing. If fundamental physiological facts are borne in mind "women who wish to remain in industrial employment should be able to do so with benefit both to themselves and to their employers."

The way in which needed health reforms in industrial management can be instituted is dealt with by Professor Collis, who holds that "modern industry wrought by progress on the anvil of utility is a tool intended for welfare." Welfare departments in factories with supervisors, doctors, nurses, and dentists are strongly advocated to remedy the complaint put forward by workers that "their hours should be so long and their wages so small, their lives so dull and colourless, and their opportunities of reasonable rest and recreation so few." Interesting details as to personnel and duties to be undertaken are given from the experience of the Ministry of Munitions. The book concludes with lectures by Mr. Fleming and Mr. S. Florence on the need for and the methods of carrying out industrial research. It is readable throughout, and contains information with which every industrial medical officer should be familiar, and be glad to have it at his disposal.

A ST. HELENA WHO'S WHO.

A Directory of the Island during the Captivity of Napoleon. By ARNOLD CHAPLIN, M.D. Cantab. London: Arthur L. Humphreys. 1919. Pp. 257.

EVEN the smallest or most trivial occurrence connected with Napoleon is of interest, and although Dr. Chaplin's book is mainly a chronicle of trivialities, it is well worth reading as a record of the people among whom a great man and a fallen Emperor passed the last years of his life. Dr. Chaplin has managed to collect details of apparently everyone who was resident in the island during the captivity, from Sir Hudson Lowe down to the odd job man at Longwood. And society in general seems to have much resembled that described by Mrs. Sherwood in the "Fairchild Family" and "Little Henry and His Bearer." There was a worldly and, to put it mildly, none too moral a section, while another section was severely Evangelical, and used to offer up nightly prayers for the salvation of Napoleon's soul. Slavery existed, but was finally put down by the H.E.I.C., with the voluntary agreement of the island and at the instigation of Sir Hudson Lowe, in 1818. One of the most interesting personalities on the island was the Rev. Richard Boys, senior chaplain. He was a divine of extremely rigid and uncompromising views, one, in fact, who would have been the delight of the Dowager Countess of Southdown, and whether from desire of Heaven or from fear of Hell, the morals of the island underwent a vast improvement from his efforts. Thus, in 1813 the illegitimate baptisms were 198; in 1815, when Mr. Boys was appointed, they fell to 58; in 1820 they were 17. During the years 1822-1825 the island underwent a religious revival owing to the exhortations of Mr. Boys, and the numbers for these four years were respectively 6, 3, 4, and 7. He was obviously tactless and narrow-minded, but absolutely fearless in doing what he believed to be right. In July, 1821, a few days

before the departure of Lowe and his staff, Boys preached a sermon which gave rise to much surprise among its hearers. No copy of the discourse is extant, but Lowe was so much struck by it that he made a careful analysis of it, which he submitted to the Council on the day following. Lowe's précis will be found in Dr. Chaplin's book. The text was, "Verily I say unto you, that publicans and harlots go into the Kingdom of God before you," and the sermon was evidently of the kind which made Lord Melbourne say, after hearing a similar discourse, "Things have come to a pretty pass when religion is allowed to invade the sphere of private life." However, the indomitable Mr. Boys, after coming to grips with the Council, retained his position until 1830, when he retired on a pension, and we think that the Council deserves credit for its attitude towards him, having regard to contemporary modes of thought.

Dr. Chaplin's last chapter brings to mind those romances of our boyhood which always left off at a critical juncture—e.g., "At this moment the arras parted and the figure of a monk appeared who bore a knotted whip." For Dr. Chaplin mentions the fact unknown to most people that besides the Lowe papers in the British Museum there exists in the custody of the Court of Chancery a large collection of documents left by Major Gorrequer, military secretary and A.D.C. to Lowe, nearly all of which deal with the captivity, including Gorrequer's private diary. In 1855 these were considered by Gorrequer's executor to be too secret and confidential to publish, and in 1881 Mr. Vice-Chancellor Bacon made an order for these documents to be kept by the Court. At this date, however, we should imagine that no one's feelings would be hurt by their publication at least in part, and as they are probably of extreme interest it may be hoped that the information contained in them will see the light. In the boyhood's romances the promise of "to be continued" was always kept.

A PRACTICAL TREATISE ON OPHTHALMOLOGY.

By L. WEBSTER FOX, M.D., LL.D. London and New York: Appleton and Co. 1920. With 6 coloured plates and 300 illustrations. Pp. 831. 35s.

IN the main this work follows the lines of previous text-books. The author's claim that in this new edition he presents all the modern thought and practice of ophthalmology can hardly be allowed. No ordinary text-book could possibly do this, nor is it desirable that it should. Take glaucoma, for example. Its pathogenesis opens up wide problems whose solution is yet to seek, and the same is true of most forms of choroiditis and retinitis. A text-book should give some idea as to what these problems are, but can hardly be expected to give all the various attempts at solution which different authorities have proposed. Similarly with regard to the operative treatment of conditions, where many alternative operations are possible selection is indispensable.

So far as it goes, this book is a reliable guide for the student. The ophthalmic surgeon will be chiefly interested in the description of an original operation for conical cornea, and perhaps in an original illustration showing colloid growths of the retina. The Elliot operation for glaucoma which is now well established is described by Colonel Elliot himself in an appendix, but it is a pity that the description is not accompanied by illustrations. The general get-up of the work, the print and style of illustrations, are all that can be desired.

THE PILGRIM'S BOOKS.

No. 2: Toasts, Rakes, and Cits. London: Philip Allan and Co. 1920. Pp. 256. 5s.

THIS little collection consists of papers from the *Tatler*, for the most part written by Addison and Steele, although some few are by other hands. They have been selected so as to show modes and manners, mainly urban, in the eighteenth century. Talleyrand said that no one could form any idea of how pleasant life could be who had not lived before the French Revolution, and certainly the life depicted in eighteenth-century light

literature paints a most graceful and happy existence for the upper and even for the middle classes. As for "the swinish multitude," they certainly had more of the hardships of life than anything else, but they enjoyed themselves hugely in a coarse and somewhat brutal manner, and apparently there was nothing like the unrest which is so obvious to-day. The curious thing about the eighteenth century was the admixture of coarseness with extreme refinement. Think of Swift's picture of society as drawn in his "Polite Conversation" in his poem describing a lady's bedroom, and of the incidents described by Lord Robert Seymour in his diary, and compare these with the grace of the dress, the outward show of courtesy and dignity in manners, the art of Gainsborough, Reynolds, Romney, and Cosway.

To read the *Tatler* and *Spectator* is always a delight, and this little book will be a pleasure to many who have not the time or the energy to read the somewhat voluminous originals. One paper, that on p. 217, entitled "Dr. Young," is of special interest to our profession as giving an amusing picture of a quack.

JOURNALS.

Journal of Pathology and Bacteriology. Vol. XXIII, No. 3. Pp. 241-370.—The Cultivation and Isolation of *Bacillus tetani*, by R. S. Adamson. To isolate the tetanus bacillus from septic wounds the author recommends culture in alkaline (—10 or —20) broth, either anaerobically or aerobically with *Bacillus proteus*. These mixed cultures give good yields of toxin, and any suspected culture should be grown for 4 to 8 days and then inoculated into a guinea-pig.—The Biochemistry of *Bacillus edematiens*, by C. G. L. Wolf. Exact analysis of cultures shows that this anaerobe is both proteolytic (like *B. sporogenes*) and saccharolytic (like *B. welchii*).—The Influence of Glycerine on Certain Streptothrixes Isolated from Malignant Growths, by A. S. and H. G. Leyton. Three strains growing white on plain agar produced abundant yellow pigment on the addition of glucose and glycerine.—On the Antitoxic Content of Some Gas Gangrene Sera Used in the Later Stages of the War, by H. Henry.—The Precipitation of *B. welchii* Toxin, by H. Henry and M. Lacey. The toxin of *B. welchii* reaches its highest value in meat-broth cultures in 12-24 hours and thereafter rapidly depreciates; it is also inconveniently unstable in the filtrates from such cultures. The highest potency is also relatively small, a good preparation containing no more than 10 mouse minimal lethal doses per c.c.m. A stable concentrated toxin may be obtained by precipitation by ammonium sulphate or alcohol, and best by dissolving the precipitate obtained by two-thirds saturation with ammonium sulphate in water and reprecipitating by the addition of four volumes of alcohol. This is very useful both for immunising horses and for titrating their sera and keeps without deterioration.—The Anaerobes Responsible for Gas Gangrene in Man, by H. Henry and M. Lacey. The isolation and identification of the anaerobic bacilli from cases of gas gangrene is very difficult. The authors have used guinea-pigs protected against one or more species by a preliminary injection of specific antitoxic sera; the animals then act as differential filters, allowing those organisms only to grow and invade the blood against which they have not been immunised. In 50 consecutive cases examined in this way *B. edematiens* was found five times and *B. fallax* twice, the rest being *B. welchii* or *Vibrio septique*.—A Comparative Study of Experimental Bilharziasis in Monkeys contrasted with the Hitherto Described Lesions in Man, by N. H. Fairley. The original must be consulted for this valuable description of the symptoms and anatomy of monkeys infected in Egypt with *B. mansoni* and *B. hematobia*, which throws much light on the human disease and on the differences between the two parasites.—The Fate of "Washed Spores" on Inoculation into Animals, with special reference to the Nature of Bacterial Toxæmia, by F. H. Teale and E. Bach.—The Relation Between the Quantity of Serum Administered and the Active Immunity Produced in the Simultaneous Vaccination against Hog Cholera with Virus and Serum, by T. B. Haslam. Large quantities of serum do not interfere with active immunisation.—Spirochaetal Jaundice: the Morbid Anatomy and Mechanism of Production of the Icterus, by J. W. McNee. From a study of five fatal human cases and experimental guinea-pigs, the author concludes that the jaundice is due to destruction of liver cells and not to excessive hæmolysis or biliary obstruction as has been supposed.—A Saccharomyces in Mesenteric Glands of the Human Body, by T. Tanaka.—Comparison of Structures of Red and White Cells, by E. Emrys-Roberts. Reflections on the fact that leucocytes shrink on drying in a different way from red cells.—A New Pathogenic form of Streptothrix, by A. G. Gibson. Isolated from a

spleen excised from a case of acholuric jaundice.—Variation in Bacteria in Relation to Agglutination by Salts and Specific Sera, by J. A. Arkwright. Cultures of Shiga's dysentery bacillus and other organisms yield two forms differing widely in their agglutination reactions and mode of growth.—A New and Simple Criterion of a Positive Wassermann Reaction based on the Analysis of over 2000 Quantitative Tests, by C. H. Browning and E. L. Kennaway. If the amount of complement giving just complete lysis with the negative control serum is reckoned as 100, any serum giving complete lysis with 200 complement or more is positive, those taking 150 or less negative and the rest suspicious.—The Specific Relationship of Heterogenetic Antibodies to Certain Tissue Lipoids, by T. Taniguchi. The injection of guinea-pig organs into rabbits gives rise to immune body for sheep red corpuscles in the latter's serum; alcoholic extracts of the antigen can inhibit the immune body.—A Source of Fallacy in the Wassermann Reaction depending on Heterogenetic Antibody in Human Serum, by T. Taniguchi. Human serum not infrequently contains heterogenetic sheep hæmolysin; it is therefore not safe to use alcoholic extracts of heterogenetic antigens (guinea-pig or horse heart) in the Wassermann test.

In the *Journal of the Royal Army Medical Corps* for July Captain S. H. Daukes tells how many were the schools, how valuable the courses in military hygiene that were required during the war to provide R.A.M.C. officers and men to fill the sanitary sections which kept the armies on the various fronts free of preventable disease. At Chelsea, Leeds, and Blackpool the schools each did a great work for the war, and we hope their influence is still active in the country now the troops have come back. The story is one that all should read to learn how much a skilful civil practitioner must acquire before he is fully efficient as an army officer.—Captain F. E. Reynolds reports from Baku that agglutination of proteus vulgaris emulsion in 1/100 dilution (Weil Felix reaction) is evidence that the case concerned is one of typhus fever, also that negative results during the second week of a pyrexia exclude acute typhus fever as a diagnosis.—Lieutenant A. W. J. Pomeroy describes how he materially reduced mosquitoes and malaria at Dar-es-Salaam in German East Africa. The Germans had decided to fight malaria here by quinine only, the destruction of mosquitoes being, it was thought in 1912, too large an enterprise. Lieutenant Pomeroy, who was entomologist in South Nigeria, thinks it is better to abolish mosquitoes by doing away with their breeding grounds. He had 50 natives permanently at work, sometimes 200. They drained the swamps, cleaned up the house-yards, oiled the waters he could not drain, put fish in the drains to eat the larvæ, and kept cattle off the swampy grounds, as their footprints made troublesome breeding places. As stegomyia and culex were diminished as well as anopheles, the town became more comfortable as well as healthier. Ointments are little good to keep mosquitoes away; that most recommended is made of equal parts of soft soap, paraffin, and eucalyptus oil.—A very suggestive lecture on Gas Poisoning, given by Dr. C. G. Douglas at the Royal Army Medical College, is reported. The Germans used four kinds of poison gases: (1) acute lung irritants, "green cross," chlorine, phosgene, &c., causing acute pulmonary oedema; (2) lachrymatories, as xylol bromide; (3) vesicants, "yellow cross," mustard gas, scorching and blistering skin and mucous membrane—the necrosed mucosa might become secondarily infected, when broncho-pneumonia might follow and cause death; (4) sensory irritants, "blue cross," chlorarsines, acting on the mucosa of the respiratory tract causing burning and aching pains, nausea, and mental depression. At first gases came drifting over in clouds, later in shells, or from projectors which discharged gas in great volume over a restricted area, securing a high concentration. Against the earliest attacks we had no protection; later, with an effective respirator and good discipline, casualties and fatalities decreased. In the last 15 months of the war the army had 160,526 gas casualties (14 per cent. of the total casualties experienced), and of these only 2.5 per cent. died. Four-fifths of these 160,526 were due to mustard gas. Those badly gassed with chlorine were apt to develop acute pulmonary oedema and to die within two days. Such cases could not be allowed to walk; they must be carried on stretchers, and their great number at one time made tremendous difficulties for the bearers. Mustard gas caused casualties rather than fatalities, and if men wore their gas masks few died. Gas attacks were terrifying—the numerous casualties occurred so suddenly. As time went on the period under treatment was always being shortened, particularly in France. There were few sequelæ; the most common was the "irritable heart syndrome," shown by Haldane to be largely neurasthenic. It follows that gas poisoning should be treated near the front, for cases took months to recover in England against weeks in France—a serious thing. Not only were the men wanted in France, but their unnecessary care in England absorbed equipment and workers.

THE LANCET.

LONDON: SATURDAY, AUGUST 14, 1920.

The L.C.C. and the M.A.B.

THE embarrassing position of London in matters of health administration has always been recognised by those who study local organisation, and the problem of developing, and where necessary re-modelling, that administration, when the health of so vast and heterogeneous population is concerned, is admittedly one of unending difficulty. The existing position of the Metropolitan Asylums Board, and the proposals that were recently made by the London County Council for its modification, form a very good example of the complexities that have to be unravelled before arriving at a working plan, and of the unlikelihood that any plan should escape criticism.

A report was submitted recently to the London County Council by its Special Committee on Health Administration, dealing with the organisation of health services in London. A general survey of health administration in London had previously been prepared by the Clerk and the Controller of the Council,¹ and armed with this information the Special Committee defined the general lines upon which the organisation of London health measures should be developed, if those lines were to be elastic in character, so as to allow for adjustments and alterations when brought about by the requirements of new legislation. The report of the Special Committee followed the general objective of the Ministry of Health Act, 1919, in that its scheme aimed to bring all the health services concerned under a unified control. The development of these services, as set out in the report, which should be studied, showed the responsibilities of the London County Council for local sanitary work, for the treatment of infectious disease, and for the provision of school medical service, while the relations of the Council towards the treatment of the insured were described, as also the measure of coöperation extended to various voluntary health organisations. The difficulties and anomalies in this congeries of health services were categorised and the existence of overlapping and deficiencies honestly stated; and a series of recommendations were arrived at. These recommendations, which together with the report received the endorsement of the Council, proposed that the health functions of Poor-law authorities should be divided between the Council, the City Corporation, and the Metropolitan Borough Councils in accordance with the MACLEAN Report,² and that the administration in London of future health services should be similarly entrusted, the Council being the central organising

authority. It was further recommended that the Council should have power to appoint a Health Committee composed of its own members and of experts, to whom the various duties accruing under the scheme could be referred. The cost was allotted in particular ways, it being advised that the cost of the prevention of infectious diseases should be borne equally by national and local funds. The scheme of the Special Committee of the London County Council made particular reference to the Metropolitan Asylums Board, as possessing an "anomalous constitution" under which it had "certainly performed its duties very efficiently." Further, it assumed that "the institutions of the Metropolitan Asylums Board and its highly competent staff would be transferred *en bloc* to the Council," it being at the same time "desirable that the Council should have the benefit of the experience in hospital management of the members of the Board." The Council and the Metropolitan Asylums Board have always worked in friendly coöperation, but the latter body is not appointed by direct election, and while the Council determines the amount of accommodation which it asks the Board to provide for the infectious sick and other purposes, the Board makes the provision without control by the Council of the expenditure, and the cost falls on the poor-rate. The expenditure is thus jointly determined by two bodies, neither of which is in the position to control it.

There certainly seems room here for change, and the design of the London County Council was referred by the Metropolitan Asylums Board to its General Purposes Committee, which was asked to report on the new proposals of the Council for the administration of the health services of London in so far as the constitution and duties of the Board were affected. This report³ constitutes a reasoned decision on the part of the Metropolitan Asylums Board not to seek inclusion in the scheme of the London County Council. The report recognises the cordiality of the references made to the work of the Board, while pointing out that the Board might have been consulted before the scheme was drawn up. The essential criticism of the report of the Board upon the scheme of the London County Council is that it goes at the same time too far and not far enough. The General Purposes Committee of the Board affirms that such an authoritative inquiry as that proposed by the London County Council should be undertaken by the Government, and that London health administration should therein be considered as a whole. Extension of boundaries, the constitution of a Central Council with local legislative powers, and the relations between this legislative council and administrative departments should, it considers, be settled before important changes in individual branches of medical services are made. Pending such a Government inquiry it recommends that, as far as the Metropolitan Asylums Board is concerned, the present needs can be met by the London County Council and each borough council being afforded representation on the Board, whose name, it states, should be altered to some style conveying its duties. Certainly no one would guess from its name that the Board provides hospital accommodation for infectious sick as well as for certain classes of sick children, defectives, and tuberculosis subjects, while con-

³ Metropolitan Asylums Board: Report of the General Purposes Committee re Prospective Legislation, July 31st, 1920.

trolling an ambulance service and training ships. The report of the General Purposes Committee of the Metropolitan Asylums Board is an interesting criticism of the virtues and vices that may underlie centralisation. There are 50 residential institutions under the care of the Board, in which there may generally be found some 16,000 patients and a staff of 9000. The business of the Board—its works, finances, and supply arrangements—occupy the time and energy of 73 members, and it is by the personal interest of a large body of representatives giving a large proportion of their time to the special work that the welfare of the persons is secured. Absorption into the London County Council would probably result in a diminution of the personal services given by representatives for whom there would be no place on the County Council, and who might not desire or would have no opportunity to take part in the general work of the Council. This might be only a temporary occurrence, but we have here none the less a strong argument for devolution to be set against the known merits of centralisation, while we must remember that one of the merits of centralisation is not necessarily economy.

A Census of Cripples.

EVERY social worker in the large cities of this country is struck by the high proportion of physical defects among the children in the poorer areas. Some idea of the number of cripple children in London may be gained from a study of Dr. W. H. HAMER's recent annual report as school medical officer for the metropolis. During the year 1919 the number of new cases deemed suitable to attend schools for the subjects of physical defects—termed in the report "P.D." schools—was 1184, namely 638 boys and 546 girls. And further analysis showed that 203 of these children were the victims of infantile paralysis, 52 of cerebral and 17 of other paralyzes; 317 others were crippled as a result of non-pulmonary tuberculosis, 61 from congenital and 68 from post-natal deformities. No one supposes that these figures in any way cover the sum of deformed childish bodies in the metropolis. Rickety manifestations were actually found in over 3 per cent. of boys on entering the public elementary schools, and among older school-girls 2·7 presented deformities of some kind, chiefly spinal curvature. A few years ago Sir GEORGE NEWMAN estimated the total number of cripple children in England and Wales as between 30,000 and 35,000. The number is sure to be below the mark, for the lusty child is not a gentle critic of physical defect in his brothers and sisters, and the cripple child is liable to court obscurity.

It is therefore not a small service on the part of the recently formed Central Committee for the Care of Cripples that it is carrying out a house-to-house inquiry in certain typical rural and industrial areas, in order to obtain an accurate census of physical defect. A similar census taken in Cleveland, Ohio, in 1915-16, and another by BIESALSKI for the whole of Germany in 1906-08, revealed a hitherto unsuspected prevalence of disability. For the Cleveland inquiry, cripples were defined as persons handicapped from lack of the normal use of the skeleton or the skeletal muscles. The inquiry was carried out by a voluntary association employing unskilled visitors to make a house-to-house visitation, and experienced visitors to fill up the forms. An endeavour was made to ascertain

in advance the number of cripples by asking for returns from associations engaged in health or social work, hospitals, ministers, and others; but the actual visiting led to the discovery of 65 per cent. more crippling than was known to all these agencies. In the German inquiry the definition of cripple was much more exhaustive—namely, "an invalid (in consequence of hereditary or acquired disorder of nerve, bone, or joint) deficient in the use of his body or limbs to an extent which makes it impossible for him in the social environment in which he finds himself to direct his remaining bodily and mental capacities towards the achievement of complete economic independence without the help of an institute which offers him combined facilities for medical treatment and education." The work was carried out by postal inquiry and covered the whole of Germany. Extremely full and detailed forms were issued, containing a large number of questions as to any possible crippling physical defect, the householder being legally compelled to furnish replies. A thorough analysis of the returns—excluding Bavaria, Baden, and Hesse, which did not reply in time—appeared in 1909 in book form.¹ The census now in progress at home is not only giving a similar basis on which to apply preventive and curative measures, but is awakening in the localities chosen an interest in their own quota of defect and the provision made for dealing with it. The honorary secretaries of this Committee are Miss BEASLEY, Mrs. TOWNSEND, and Mr. G. R. GIRDLESTONE, F.R.C.S., and any inquiries or information will be welcome at 20, Berkeley-street, London, W.1. Naturally, action is not to be limited to ascertaining the extent of the problem, but the Committee has wisely decided not to interfere with the work of any existing agencies concerned with the care of cripples, but rather to assist and coördinate their efforts and to help any local authority or voluntary organisation desirous itself of making better provision for these children.

And there is a special reason for an effort on behalf of cripple children at this particular juncture. Experience gained during the war has brought out the value of expert orthopaedic treatment for many injuries and physical disabilities that would formerly have been left unrelieved. Orthopaedic departments of general hospitals and special orthopaedic hospitals in Poor-law and other buildings have been dealing daily with scores of cripples and potential cripples, the result of the injuries of warfare. Some of these hospitals, with their teams of experts and admirable equipment, have been dismantled, and others will follow suit as the supply of war cripples in need of surgical help and training gradually diminishes. It would be lamentable if the opportunity were not utilised to tackle the problem of the child cripple. For it must be remembered that every cripple left without proper treatment and education means one more useless member of society, unable to earn an adequate livelihood, and yet for the most part with undiminished prospect of length of days. Before it is too late we urge on those who are at the focus of administration not to let slip an opportunity of turning the experience of war into the kindly fruits of peace, one which may never recur in our generation.

Annotations.

"Ne quid nimis."

WORKING OUTPUT.

THE reports of the Industrial Fatigue Research Board as they increase in number are forming a special literature which is throwing light on the working of the human machine, and which cannot fail in time to display how health may be maintained and how early manifestations of disorder may be detected. The publications fall naturally into various groups as they deal with general topics or with this or that industry or group of industries. The most recent report,¹ one by Dr. H. M. Vernon, belongs to the former category and deals with the rate at which the effect, as measured by output, of shortening or lengthening hours of employment is manifested. The subject is one of considerable interest to-day, when hours of work are being curtailed in nearly every branch of industrial activity, and employers are eager to know whether to expect as large an output as before, and if so, how soon.

Dr. Vernon brings together data, some of which have been scattered through other publications referring to various trades, issued during several years. Information is thus drawn from the manufacture of steel, the tinplate industry, and the production of shells. Certain conclusions are arrived at as the result of comparing the statistical data quoted, conclusions which are of interest not only to the industrial economist, but also to the student of the metabolic activity of health. Dr. Vernon finds that when hours are shortened work at first proceeds for several weeks at the old rate—that is to say that there is a marked latent period, unless some incentive to more rapid work is placed before the workers. Then the workers, apparently quite unconsciously, begin to work faster as they find the energy at their disposal is greater than what they are expending. "They unconsciously speed up a little from time to time, and in that they suffer no over-fatigue in consequence, they get into the habit of working steadily at a higher level of speed. From this level they make further unconscious attempts to speed up, till they finally arrive at an approximate equilibrium of speed in relation to their hours of work." The increase continues to operate in heavy and complex processes, such as open-hearth steel melting, through as long a period as 12 months before a new and higher level is settled down to; in simpler operations, such as those of fuse-making, the new level may be attained in four months. Intermediate periods may be expected to elapse in the case of less heavy or less simple processes. In other words, the speed of human activity is a function of the weight of work and the period of employment, and there is a tendency for the expenditure of energy to be the same whether the hours be long or short. Dr. Vernon further points out that with long hours a certain proportion of the energy available is expended in "passive work" rather than in productive work, where passive work is held to include standing about doing nothing which in itself will finally cause fatigue; but when there are shorter hours this energy is saved and can be diverted into productive work. The result upon speed produced by lengthening hours is of even more practical importance to employers than that of shortening hours, owing to the use of overtime. Here Dr. Vernon finds little or no latent period before the rate of output accommodates itself to the longer hours. Any attempt to continue work at the pace suited to shorter hours would use up the available energy and leave none for the overtime hours unless reserves were called upon and the realms of over-fatigue invaded. We find here a scientific explanation of the saying, "overtime does not pay." The suggestion is put forward that when overtime becomes a necessity the additional hours should be spread evenly through the week, for example, it would be better to work nine

hours each day instead of ten hours on alternate days. The resulting rate of work would then be that suited to a nine hour day; while by working ten hours on alternate days, the rate of work for every day of the week would become that suited to a ten hour day. Further, when overtime is no longer needed, a shorter period would elapse in recovering to an eight hour pace from a nine hour pace than from a ten hour pace. Evidence is also adduced to show that more time is lost on heavier work than on lighter work, and during longer hours than shorter hours. Thus women employed on rather heavy work lost 6·7 per cent. of time, as contrasted with women on rather light work, who lost 4·2 per cent.; while men employed for 63½ hours per week lost 11·8 per cent. of time as contrasted with 6 per cent. when working 54 hours per week.

These facts suggest that there is a certain amount of energy at the daily disposal of the human machine; that there is a definite urge forward to expend this energy, an urge due to the anabolic activity of rest stimulating the katabolic activity of work; and that when the two balance one another a level of productive activity is maintained. Practice may increase productivity still further, but practice only consists in using energy economically, so that more things are made with the same exertion previously required for making fewer. Interest also centres on the fact that quicker work during shorter hours is associated with less lost time (represented by sickness), from which health appears to be a function of activity; and, from the viewpoint of health, there appears to be an optimum rate of activity for the human organism which seems to coincide with the optimum rate of production. We have here direct evidence of the way in which the work of the Industrial Fatigue Board bears upon two most important national needs—industrial productivity and health. The Board will indeed justify its existence if it is able to convince those who control the destinies of the industrial world that material wealth and individual health depend, so far as labour is concerned, on the same factors.

HERPES ZOSTER AND CHICKEN-POX.

CONSIDERABLE interest has always attached to the comparatively trivial ailment, herpes zoster or shingles, owing to the apparent connexion between its points of outbreak and the distribution of nerve branches, making it an obvious example of so-called trophic influence—the direct influence of nervous stimuli on cell nutrition. How this stimulus is brought into play in the case of herpes has remained obscure. It has been suggested that it represents a condition of the sensory side of the central nervous system closely resembling or identical with that which on the motor side constitutes acute anterior poliomyelitis, while the frequency of the outbreak of labial herpes as a concomitant of several different infective fevers—pneumonia, cerebro-spinal fever, coryza, and so forth—would tend to indicate that a variety of different poisons are equally capable of exciting the underlying nervous disturbance. Apart from the fact that the essential lesion of herpes is a simple vesicle, and so resembles the exanthem of chicken-pox, there is nothing at first sight to suggest any further connexion between the two conditions. Some curious instances have, however, been recorded in which infection with varicella has followed contact with a sufferer from herpes zoster, and the suggestion has seriously been made that the latter is in reality a localised varicellar eruption. The question is discussed in an interesting paper by Dr. Claude B. Ker, which appears in our present issue, with the practical conclusion that much stronger evidence than any at present brought forward will be needed to establish so novel an identification. With two such relatively common diseases coincidence is hard to eliminate. The cutaneous manifestation of chicken-pox may be reduced to a very few spots, even to one single vesicle, while the clinical phenomena are so slight as easily to escape notice—facts which render it difficult in any case to eliminate the possibility of some overlooked source of infection. Indeed, if the rash may be reduced to one

¹ The Speed of Adaptation of Output to Altered Hours of Work. By Dr. H. M. Vernon. Report No. 6. Industrial Fatigue Research Board. 1920. Pp. 35. 1s.

vesicle, it seems probable that cases exhibiting no eruption at all may from time to time occur, and without the typical rash they would be quite impossible to identify. On the other hand, it has been stated that there may exist a generalised form of herpes with scattered lesions closely resembling varicella. The distribution of the vesicles is typically along a particular nerve; but it is not unlikely that more than one nerve may be affected at the same time, giving rise to the simultaneous appearance of characteristic groups of vesicles in different parts of the body. Seeing that the eruption of chicken-pox may in some instances be localised in areas of special irritation, such cases might give rise to difficulties in diagnosis. Dr. Ker suggests that the question of the relationship between herpes and varicella is one in which the general practitioner is in the most favourable position for making observations, and hopes that some among our readers may contribute data towards a solution of the problem.

SECRET REMEDIES IN AMERICA.

THE Proprietary Medicines Bill has passed the Committee stage in the House of Lords, and this should turn English legislators to examine the success which has crowned the efforts of American reformers in a similar direction during the last 15 years. By the Federal Food and Drugs Act the sale of "misbranded" drugs became illegal. For five years it was held that a drug was misbranded if the description published on the package or label claimed a cure for diseases which in effect the drug did not cure. Later a decision of the Supreme Court confined this term to descriptions of composition and sources of origin. But during those five years many significant changes appeared on the labels of proprietary medicines. California syrup of figs, which has preserved its old description in Great Britain even to the present day, was known in America, from the passing of the Federal Act, as syrup of figs and elixir of senna. The American also is told that the mixture contains 6 per cent. of alcohol—a fact of which many Englishmen are doubtless in ignorance. In other cases the change was more radical. The labels on Dr. Kilmer's swamp root as sold in England continued to assert—

"It cures enlargement of prostate gland, seminal weakness, spermatorrhœa, generative debility, and general languor. Drives malarial poison out of the system purifies the blood."

In America the following modest claim had to be substituted:—

"It will be found very beneficial in cases of debility."

Such illustrations are instructive as evidence of the possibilities of legislation in combating this dangerous trade. The Food and Drugs Act has been in force for nearly 15 years and there are still many fraudulent and thriving concerns in America, but with English co-operation their days are now numbered. The American federal authorities are also able to prosecute any firm which can be shown to be "conducting a scheme for obtaining money through the mails by means of false and fraudulent pretences, representations, and promises." Against such firms a fraud order is issued and the business is closed down. In a leading article which appeared in THE LANCET of June 12th (p. 1274), before the present Bill was introduced, we set out the amazing story of the "Medical Mail Order Frauds" in America, coupling the toast with the name of sargol.

More than any other single organisation the American Medical Association have been responsible for the advances which have been made. Their propaganda began when in the year 1905 they reprinted in booklet form a series of articles which had been appearing in *Collier's*. That was the beginning of their public campaign, although for some years previously they had directed their efforts to eliminating certain proprietary articles from the armamentarium of American practitioners. Since 1905 the journal of the Association has published many articles exposing various nostrums and many of these articles have been reprinted. The earlier ones have also been collected into

book form.¹ The Association maintains a Council of Pharmacy and Chemistry, which decides not only the therapeutic merits of the advertised prescriptions, but even the more delicate question of whether a harmless concoction is being sold at too high a price. Naturally, a chemical laboratory is kept busy analysing and researching into the value of various orthodox and unorthodox remedies. In the matter of propaganda—for which a special department has been created—they are careful to insist that their work is educational and not punitive. Their office is richly furnished with references and cross references, stored by the card-index system, and has become a clearing house of information on medical frauds of all kinds. The poster has of late been used with success for popular education. A catalogue of these posters is sent gratis on application, as well as a list of the publications of the department.

A GREAT GIFT.

THE example set some time ago by the Shell Company, which gave £250,000 to Cambridge University for the general improvement of scientific teaching and training, with no conditions attached to the gift, has been followed by the British Dyestuff Corporation, which has given a large sum to the Universities of Manchester and Oxford for chemical research. At an extraordinary meeting of the shareholders of Messrs. Brunner, Mond, and Co. on August 4th the following resolution was carried in the face of a small but energetic number of shareholders:—

"That the directors be and they are hereby authorised to distribute to such universities or other scientific institutions in the United Kingdom as they may select, for the furtherance of scientific education and research, the sum of £100,000 out of investment surplus reserve account."

This was the second attempt to persuade the shareholders to accede to the unanimous recommendation of the directors. The chairman gave an interesting analysis of what such an apparently—and actually—large gift for the promotion of scientific education, training, and research really meant when set forth in cold economic business monetary calculation. "This is how it works out," said the persuasive chairman, "on such a huge capital as that of Brunner, Mond, and Co. If the £100,000 was divided in cash it would amount to 2½d. a share gross, subject to income-tax. If it were left in the business and earned 10 per cent. it would earn ¼d. a share in interest, less tax." The example of these great business firms ought to be taken to heart by others who have lost nothing through the war. In 1911-12 the State aid received by the German universities was £1,220,000. All British universities are suffering from want of funds, and donations to them evoke a feeling of gratitude to the donors. Further, these gifts are national investments. But they should not relieve Government of its duty towards the maintenance and advancement of scientific education in this country, which ought not to be left to haphazard windfalls, subject to the vicissitudes of trade and the goodwill of shareholders in successful chemical and engineering combines. Even now, with all the trumpeting, advertising, and propaganda work, wealthy Lancashire has only subscribed £212,000 out of the total of £500,000 asked for to enable the University of Manchester to keep financially abreast of the times.

THE FUTURE OF METROPOLITAN WATER-SUPPLY.

THE report recently issued of the Departmental Committee appointed to inquire into the provisions and effect of the Metropolis Water Act, 1902, should the recommendations be adopted, affects the consumer's interests in many ways. Apart from his pocket, questions of health may arise with the suggestion of a limited supply. Briefly, the Committee considers in regard to administrative personnel that a reduction in the number of members of the Water Board

¹ Nostrums and Quackery. Chicago: American Medical Association Press. Second edition. 1912. \$1.

would add to its efficiency, and further recommends that the Board should appoint a general manager, so as to secure a co-ordination of general policy. Amongst other things, it concludes that the charges fixed under the Act of 1907 should be increased. It is suggested that the maximum rate for domestic supplies should be raised from 5 to 10 per cent., but no higher rate than $7\frac{1}{2}$ per cent. is to be imposed without the authority of the Ministry of Health. The Committee, further, does not consider that there should be a public water rate as such; but though a deficiency rate should not normally be necessary, the power to levy such a rate should be retained. It is considered that the provision for the storage of water which the Water Board is making is, in present circumstances, not extravagant, while at the same time the Committee is impressed with the large amount of the demand, and expresses the hope that the need for economy in consumption will receive public attention. Incidentally a well-deserved tribute is paid to the services of the Water Examination Department of the Board, under the guidance of Sir Alexander Houston, whose work in keeping a close watch on the quality of the supply and its maintenance and economic working is well recognised. Finally, the Committee does not think that it is necessary to continue, when the office becomes vacant, the appointment of a water examiner by the Ministry of Health. This appointment was subject to the authority of the Board of Trade, and afterwards the Local Government Board, and the stipend was paid by the various companies concerned before an amalgamation was effected. It is debatable whether the policy of charging for water service on rateable value is sound, but, of course, it is based on a pre-charge, which is not the case with gas or electricity. The meter, after all, is a measure of the consumer's usage.

ANTITUBERCULOUS VACCINATION.

AN interesting communication¹ was made to the Royal Academy of Science at Bologna by Professor G. Martinotti last May, in which he described the beneficial effects obtained by a vaccine prepared by him on somewhat new lines. This vaccine is neither a tuberculin nor a serum, but contains, among other substances, a protein derived from cultures of tubercle bacilli, which acts as an antigen and is capable of producing under favourable conditions an active immunisation with respect to tuberculosis. Ordinary tuberculin is a substance eminently toxic; in fact, it contains the toxins elaborated by the tubercle bacillus on an artificial substratum totally different from that in which the bacillus develops in the animal organism. Moreover, the chemical processes by which it is prepared are sufficiently powerful to change in a marked degree organic compounds, even if as resistant as the toxins of tuberculin seem to be. According to Professor Martinotti, the scope of immuno-therapy should not be to kill the tubercle bacilli or to neutralise their toxins, but to render the body elements resistant to their attacks and frustrate their action. It is known that the tubercle bacilli act by stimulating the body cells to proliferate. This proliferation, caused by an abnormal stimulus, does not, however, lead to the formation of other normal cells as under ordinary conditions, but of special elements, the epithelioid cells, fatally destined to perish. Once the cell has come under the influence of this special stimulus it is lost; the epithelioid cells born from it will fall into necrosis either by the action of the tuberculous toxins accumulated by bacilli which have multiplied in situ, or from insufficient nutrition due to the fact that the tuberculous process involves the blood-vessels and renders them impervious. In this necrotic detritus the tubercle bacilli will multiply, act on the contiguous cells, and form a tuberculous focus capable, by a repetition of the process, of extending throughout an entire organ, ultimately spreading throughout the whole body, if it be not in a state to oppose the necessary defences. If, on the other hand, the normal cells do not respond to this abnormal stimulus and do

not proliferate, the tubercle bacilli can remain in the body, live in the organic juices, multiply and pour into the organism the products of their limited vital activity, and hence do some harm to the organism which harbours them; but they will not be able to exert their special pathogenic activity and will not lead to the development of a true tuberculous process with all its consequences and complications. In other words, they will no longer be parasites, but will become saprophytes. This is what happens in latent tuberculous infection: many individuals, especially in populous centres, carry in their organs living and virulent tubercle bacilli which remain for a long time inactive up to a certain point. But they exert a sinister influence on organic evolution by preparing that "hypoplastic constitution" which forms the soil propitious to the development of the tuberculous process. In immunising against tuberculosis it is sought not to kill the bacilli but to render them inoffensive and saprophytic by reinforcing the resistance of the body elements, so transforming an active tuberculosis into a latent. But it must be remembered that the bacilli remain alive and virulent for a long period, and it is only after years under the most favourable conditions that a complete cure can be spoken of. In fact, in the generality of cases, the cure may be said to be provisional, and the immunising vaccination must be repeated from time to time. Over a hundred surgical cases treated by this method have been published by Professor Remedi, director of the Surgical Clinic at Siena, and a similar publication from the Medical Clinic at Modena is stated by Professor Martinotti to be already in the press. We look forward with interest to further information.

"WHAT EVERY MAN SHOULD KNOW."

WE have already noted on several occasions the decision of the Portsmouth Council to popularise by official action the methods of venereal prevention among the male population of the borough. The following is the text of the notice now issued widely by order of the Portsmouth Health Committee, and signed by Dr. A. Mearns Fraser as medical officer of health:—

1. Venereal Diseases (i.e., Syphilis or "Pox" and Gonorrhoea or "Clap") are the common result of promiscuous sexual intercourse.
2. Venereal diseases not only result in immediate suffering but are often the cause of early death. Worst of all they are the cause of blind, diseased and deformed children being born into the world, and of life-long suffering to innocent wives.
3. To avoid venereal disease the only ABSOLUTELY safe course, the right and manly course, is to avoid fornication. Male chastity, although it demands the exercise of self-discipline, is quite consistent with perfect health.
4. If any man indulges in promiscuous sexual intercourse it is his bounden duty, in order to avoid disease which he may pass on to innocent people, to adopt the following simple measures, which are the best known to medical science for preventing disease after exposure to infection.
5. After exposure to infection he should at once retire to some convenient place, wet a piece of cotton-wool with a SOLUTION OF PERMANGANATE OF POTASH OR CONDY'S FLUID and thoroughly swab the male organ—see that every part is wetted with the solution. It is of the utmost importance that this should be done *as soon as possible* after exposure to infection. (The strength of the solution of permanganate of potash is 1-1000; it can be made by dissolving in a glass of water as much of permanganate of potash crystals as will cover a sixpence.)
6. The above method of prevention of disease is based upon the fact that venereal diseases are caused by living germs which after exposure to infection lie on the surface of the skin, and the prompt application of the above solution (or, indeed, of any other effective disinfectant) destroys them before they can gain access to the system and set up disease.
7. All men are earnestly advised to abstain from the sin of promiscuous sexual intercourse. If they neglect this advice they are besought carefully to observe the above instructions. To fail in this will involve suffering in the future upon innocent women and children.

[Sentences numbered 2, 3, and 7 are printed in red ink, so that they attract the eye at the first glance; 2 and 7 are, in addition, printed in bolder type.]

Men are advised on the notice to read a leaflet, extending the teaching contained in the notice, and obtainable on application to the Health Department at the Town Hall.

¹ La Riforma Medica, July 3rd, 1920.

THE CARRIER IN FOOD POISONING.

THE possibility of food infection by contact with a carrier seems to have been well established in a remarkable case of food poisoning reported from Lambeth last week. So far it has been assumed without rigid proof that the Gaertner group infections, the cause of food-poisoning outbreaks, are of human origin, the food being infected with pathogenic Gaertner bacilli from a human source, either an actual case of paratyphoid fever or a carrier case. The subject is ably summarised by Dr. William G. Savage in his recently published book on "Food Poisoning and Food Infections," reviewed in our issue of July 10th last. The circumstances in this case at Lambeth, according to the evidence of Dr. Joseph Priestley, the medical officer of health, are as follows. The outbreak was confined to one house in which ten persons were living, all of whom were affected. One (Mr. K—e) died, and Dr. B. H. Spilsbury said at the inquest that death was due to syncope from acute enteritis. We understand that the other sufferers are now convalescent. Dr. Priestley ascertained that on Saturday a stew of steak and liver had been prepared and consumed, the gravy being saved until the following day and warmed up with a Yorkshire pudding. On the previous Thursday the wife of the landlord (Mrs. H—y) who undertook the preparation of the food, was taken ill, and the climax of her illness was reached on Saturday night, although she continued to attend to her household duties. Dr. Priestley expressed no doubt that the source of infection of all persons was the gravy from the liver, which was itself sound. The outstanding feature of the case, in fact, is that the person who prepared the food suffered from the same disease as the others two days before they were taken ill, and instead of going to bed she did the cooking for the whole of the household for two days, the result being that the liver gravy was infected. Dr. Priestley was inclined strongly to the conclusion that this person was a carrier of the bacillus, who having previously suffered from food poisoning had during culinary operations sown that bacillus in the gravy of the repast. This evidence, we learn, is amply supported by subsequent bacteriological investigation, the causative bacillus having been found present in the organs of the deceased and in the blood of those who have survived.

According to the results obtained at the Lister Institute the bacillus proved to be the "mutton" type of the large paratyphoid B group which has been comparatively recently described and named, including a large number of the strains formerly referred to as the *Bacillus aertrycke* or *suipestifer*. The coroner, Mr. S. Ingleby Oddie, brought in a verdict of "Death from gastro-enteritis by food-poisoning misadventure" in accordance with the evidence given by Dr. Priestley. The accompanying diagram furnished by him gives graphically the particulars of the outbreak. The case is a remarkable one, and, if rare, somewhat disturbing in regard to the risks involved in kitchen régime.

SIMPLE ULCERATION OF THE GENITALIA.

Dr. Noah E. Aronstam,¹ of Detroit, classifies the varieties of simple or non-specific ulcers of the genitals as follows: (1) The herpetic ulcer; (2) the gonococcal erosion; (3) erosion of the sebaceous follicles; (4) the traumatic abrasion or erosion; (5) the diabetic ulcer; (6) the tuberculous ulcer. Herpetic vesicles, either spontaneously or as the result of irritating applications, may become abraded, and the coalescence of individual erosions may give rise to a large and extensive ulcer. The diagnosis is established by the co-existence of unruptured vesicles side by side with the ulcers. Treatment consists in the application of dry dressings or the use of simple dusting powders. Gonococcal erosions of the glans and prepuce are apt to arise in the course of gonorrhoea with an elongated and narrow prepuce and may form the starting point of venereal warts. Gonococci are usually demonstrable on microscopic examination. Treatment consists in the use of mild antiseptic solutions, but occasionally circumcision is necessary. Erosion of the sebaceous follicles with which the skin of the genitals is profusely supplied is mainly due to staphylococci and is frequently met with in those who work in oil or paraffin. Small local abscesses occur within the sebaceous follicles and rupture spontaneously, leaving a crateriform opening. Caustic applications will produce a marginal or peripheral induration which may be mistaken for that accompanying a primary syphilitic lesion. Treatment consists in the application of moist dressings or solutions of lysol or bichloride. Traumatic abrasions or erosions may sometimes arise from the use of rough underwear or from excessive moisture of the parts caused by perspiration in hot weather. The lesions are very superficial, and rapidly heal up on the application of ordinary dusting powder. The diabetic ulcer is usually very extensive and may assume a serpiginous and phagedænic appearance. It differs from chancroid by never presenting a worm-eaten, undermined character and being as a rule unilocular, but resembles it in healing with great difficulty. As in all doubtful ulcers of the genitals, a urinary examination and a serological test should be performed. As a rule, in such extensive lesions sugar will be found in varying proportions. Local treatment seems to be of little avail, so that an attempt should be made to improve the general condition by a strict regimen. Tuberculous ulceration of the genitals is very rare and is usually met with in early youth. Its usual sites are the glans and dorsal surface of the penis. Phagedæna is characteristic: the ulceration is deep and the margins are indurated. In spite of repeated examination the pus may appear sterile until suddenly tubercle bacilli are discovered. Treatment in such cases is not promising, radiotherapy and hypodermic injections of tuberculin having been used with indifferent results. Dr. Aronstam concludes by drawing attention to the possibility of malignant changes supervening in these chronic ulcers, especially in advanced middle age.

¹ The Urologic and Cutaneous Review, July, 1920.

THE HISTORY OF THE CARRIER CASES.

Mrs. H—Y (Infectious 22/7/20 to 26/7/20).

THE THERAPEUTIC USE OF OXYGEN.

Dr. R. D. Rudolf, of Toronto, has published a useful paper¹ expounding the present position of oxygen therapy. For a healthy person the 20 per cent. of oxygen in ordinary air is more than sufficient to saturate the hæmoglobin and supply the necessary partial pressure in the plasma (about one-fortieth of that in the hæmoglobin), while the percentage of oxygen in the air may be reduced to 14 per cent. without causing any distress. Thus the air contains a higher percentage than is needed by a healthy person when resting. But on exertion he will soon become breathless and then, as shown by Dr. Leonard Hill, he can do more work without distress when breathing an atmosphere artificially enriched with oxygen. As Meltzer puts it, the difference between the 14 per cent. which is all the oxygen required when at rest and the 20 per cent. is a "factor of safety." While this is sufficient for the demands of ordinary exertion, it is not for emergencies. A man suffering from disease interfering with respiration may be likened to a healthy one undergoing severe exertion. Moreover, at high altitudes the partial pressure of oxygen may be less than that of an atmosphere containing 14 per cent. of oxygen, and there is no margin of safety. The least exertion may bring on dyspnoea. At a still higher altitude, as in the case of airmen, dyspnoea may come on without exertion. Again, it has been found that at altitudes of 6000 feet and over cases of pneumonia do badly, the factor of safety being now absent. Hence, at Cripple Creek (altitude 10,000 feet) in the Rocky Mountains cases of pneumonia are put on the train and sent down to the prairie level. Dr. J. S. Haldane has applied the term anoxæmia to "the condition when the rate of supply of oxygen is insufficient for the normal carrying on of life." Its causes are four: (1) defective saturation of the arterial blood with oxygen; (2) slowing of the circulation; (3) defective proportion of available hæmoglobin in the blood; (4) alteration of the dissociation curve of the oxyhæmoglobin, so that this gives off its oxygen less easily than usual. Examples of the first cause are decrease of oxygen pressure in the inspired air or interference with the passage of air to the blood. Slowing of the circulation will tend to anoxæmia by allowing the blood to dwell too long in contact with the tissues. Anæmia means want of hæmoglobin in the blood, and poisoning with carbon monoxide, nitrites, or arseniuretted hydrogen will prevent the hæmoglobin from carrying oxygen. Bohr, of Copenhagen, has shown that, if the carbonic acid in the blood be lowered, the hæmoglobin will not part with its oxygen. As to the relation of anoxæmia to cyanosis, it may be said that cyanosis always means anoxæmia, but there may be anoxæmia without cyanosis, as in carbon-monoxide poisoning when the blood is cherry red, and yet the patient may die from anoxæmia. Again, when carbonic acid is deficient, the tissues may suffer from anoxæmia, and yet the blood be red with oxyhæmoglobin, with which it will not part with its oxygen (according to Bohr's law). It should be remembered that it is the amount of oxygen in the blood plasma which counts. Normally it is about 0.35 c.cm. in 100 c.cm. It is used up by the tissues and replenished from the hæmoglobin. But by increasing the oxygen in the inspired air the amount in the plasma may be raised to 3 c.cm. in 100 c.cm. Anoxæmia, which is shown clinically by cyanosis, is damaging to the tissues, and therefore should be relieved if possible. As Dr. Haldane says, "Cyanosis may always be taken as an indication that oxygen inhalation should be considered." There are two kinds of cyanosis: (1) the leaden colour of the skin, often seen in acute respiratory conditions, when the hæmoglobin is reduced and yet the veins are not over full, and (2) the blue colour of the mucous membranes when the veins are distended. In the latter venesection, followed, if necessary, by oxygen inhalation, may be called for. The common way of administering oxygen with a funnel held near the face connected with the cylinder Dr. Rudolf con-

siders useless. Meltzer has shown that it is not possible thus to raise the percentage of oxygen in the inspired air by more than 2 per cent. Moreover, the funnel gives the dyspnoic patient a sense of suffocation. Dr. Rudolf makes the same objection to Haldane's apparatus, which involves placing a mask over the patient's face, and also to Leonard Hill's. He recommends as a much better method, one which has been used extensively in the war—administering the oxygen through a soft rubber tube inserted into one nostril and held in position by a strip of strapping. It is a wasteful method, but very efficient. Its efficacy can be increased if an attendant closes the opposite nostril during each inspiration. Under this treatment patients cyanosed from influenzal pneumonia, though treated in the open air, improved visibly in a few minutes. Not only did the cyanosis lessen or disappear, but the breathing became slower and deeper.

THE UNIVERSITY CHAIR OF RADIOLOGY.

THE Senate of London University invites applications before Sept. 23rd for the post of Professor of Radiology, tenable at the Middlesex Hospital Medical School, with a salary of £1000 a year. London schools have been honourably associated with pioneer work in the application of electric waves to the needs of suffering humanity. It was John Birch, surgeon to St. Thomas's Hospital, who founded an electrical department there towards the end of the eighteenth century and carried it on nearly single-handed for a period of 21 years. His essay on the Medical Applications of Electricity, published in 1802, had a wide circulation in this and other countries, being translated into Italian and Russian. A century later the realisation by Wilhelm Conrad Röntgen of Hamlet's promise to his mother—

You go not, till I set you up a glass

Where you may see the inmost part of you—

was taken up with alacrity by the authorities of the Middlesex Hospital, who appointed a physicist on their staff, and coördinated his work with that of the Cancer Research Laboratories, and later with the Bland-Sutton Institute of Pathology. Hence the names of Sidney Russ, W. S. Lazarus-Barlow, the late C. R. C. Lyster, H. A. Colwell, and others stand for an application of electrical method to medicine which cannot fail of its fruit in due time. The effect in animals of X ray irradiation of the thymus, which becomes thereby reduced to a mere fibro-adipose residuum; the selective destruction by the rays of spermatocytes and spermatogonia; the action of radium in diminishing the power of transmission in cancer cells: these have been among the objects of investigation at the Middlesex Hospital. With this tradition we may feel assured that the University Professorship, the first of its kind, will attract some highly capable expert whose inclinations tend towards research rather than to private practice. Provided adequate assistance is afforded to help in the routine X ray work, the opportunities offered for research at this hospital should prove more than adequate. The holder of such a post might well achieve work of great practical value, not only to the science of radiology, but also to various departments of medicine and surgery. It is not too much perhaps to hope that a specialist with original ideas might stimulate useful team-work in conjunction with the clinical staff on one side and with the chair of physics on the other.

UNIVERSITY OF PARIS: FACULTY OF MEDICINE.—

A revision course on the Application of Laboratory Methods to Diagnosis is to be held from Sept. 24th to Oct. 12th in the medical clinic of the Hôtel-Dieu (Professor A. Gilbert and Professor Maurice Villaret). The instruction will include 31 lessons of an essentially practical nature, time being left free each day for visits to hospital practice. The course includes a study-journey from Sept. 25th-29th to Evian and the principal watering places of Savoy—St. Gervais, Aix-les-Bains, &c.; it is open to French and English qualified men, as well as to matriculated students, and a certificate will be issued to each of those who take part in it. The laboratory fee is 150 francs. Details of the journey may be obtained from Dr. Paul Descomps, Clinique médicale, Hôtel-Dieu, Paris.

¹ American Journal of the Medical Sciences, July 1920.

PROVISION OF EXPERT MEDICAL AND SURGICAL TREATMENT.¹

BY A. H. BYGOTT, M.D. LOND., D.P.H.,

BARRISTER-AT-LAW; COUNTY MEDICAL OFFICER OF HEALTH FOR WEST SUFFOLK.

THERE is no line of demarcation between preventive and curative medicine. There is one science of medicine whose duty is to attack disease whenever it appears, and although the medical officer of health pays special attention to the environment of the individual, yet the large amount of treatment provided by health authorities during the last few years gives most medical officers of health a title to speak on this subject from personal experience. Moreover, because he is not engaged in a competitive monetary struggle, an M.O.H. may possess a clearer vision of what the public needs than does the practising physician. It is of vital necessity for this country that we should reconsider many phases of our social machinery, as the health and working capacity of its citizens are its greatest assets. Unfortunately, whilst realising that housing, industrial, and economic conditions of the workpeople may fairly claim our first attention, with a view to preventing the necessity for treatment at all, in the present economic condition of the country large reforms in these matters must take a considerable amount of time to evolve. Twelve years' medical inspection of school children, the attention that has been paid within the last few years to maternal and infant welfare, and especially the results of the examination of most of the adult manhood during the war, show that there are in this country a large number of people needing adequate medical treatment who are not getting it. This leads to the loss of a considerable amount of working capacity which the State badly needs, and tends to dwarf the minds of thousands of people, rendering them discontented and dangerous to the State; a C3 body is often associated with a C3 mind. Many keen young men returning from the different theatres of war are profoundly dissatisfied with the present state of things, and wish that medical service shall be placed on a dignified and business-like basis. This volume of young vigorous thought, added to the considered opinions of many of the older members of the medical profession who have fought unsuccessfully against these adverse conditions for many years, needs to be organised and directed so as to secure the attention it deserves.

It is now acknowledged that the primary necessity for getting effective improvement is a greater enlightenment of public opinion. It must be remembered that we have only had a national system of elementary education for about 50 years; that knowledge of anaesthetics is only some 70 years old, that of antiseptics 50, and that of the bacterial causes of disease only some 35 years old; we have not really had much time to build the solid edifice of first-rate medical service that we need. We have left behind us the day when Dr. Abernethy made that scathing indictment of his professional colleagues, that they put drugs of which they knew nothing into bodies of which they knew less. The chief work of the practitioner of to-day is to recognise any failure from health as soon as possible, and to place the patient under proper conditions for recovery, with the assistance of skilled technique, and special surroundings such as country environment where these are indicated. The day of the apothecary who seizes upon some prominent symptom of disease, often a valuable danger signal, and covers it up and masks it as quickly as possible with some soothing drug, is drawing to a close. Doctors were never able to do so much for their patients as they can now, but the work must be done in an entirely different way to that adopted 30 years ago. The first need for expert medical and surgical services is that they shall be up to date, capable of progressing, and that all the lessons learnt in the war as to handling

and treating the sick shall be utilised to their fullest extent.

The Need for Help from the Public.

When these questions are brought forward for discussion there is often a tendency on the part of the public to regard them as too difficult and technical to be understood, suggesting that they should be left to the medical profession, and there seems to be a widespread view that there is some medical authority behind the scenes, which is responsible for improvement in medical matters. This vague authority does not exist and any improvements in organisation must come from the public themselves. It is not possible for the man in the street to decide whether ipecacuanha or squills is the better drug to use in some particular case of pulmonary disease, but he may be able to express a better opinion than some medical men, who do not take a broad view of such questions, as to whether hospitals should be situated in densely populated areas in large towns as at present; or whether most of the work there should, with our better means of transport, be done under rural surroundings, the present hospital becoming a casualty station. He should consider such questions as to whether it is sound economics for probably nine-tenths of the surgical work in this country to be done in hospitals without payment to the medical staff, so that the burden of the other tenth is laid upon one section of the community only; this procedure presses very hardly upon those persons just outside the hospital class if an important operation is required for the bread-winner, who may be leaving his dependents to the mercy of the world. These are problems capable of being solved by ordinary intelligent people, and the knowledge that the engineer has of the specialisation of function by craftsmen in the engineering trade, or that of the schoolmaster, working in a school where different subjects are taught by different people having special knowledge of them beyond that of a good general education, may well be applied to such questions as this.

Considering that specialised treatment as we know it has been built up within the last 70 years, and a great deal of the technique comparatively recently, we have first of all to consider what responsibility the patient has in the matter. He would be much more likely to seek assistance early if he were better educated in the knowledge of the incidence of disease so that he might consult a doctor when certain signs, which may lead to serious consequences, first appear. At the same time, he must be taught that no treatment can hope to be successful unless the patient coöperates in his own cure. The practitioner and district nurse form the first line of medical defence and no provision of expert services can be successful unless it gives the fullest scope to the activities of these persons. The practitioner must be provided with proper working conditions, so that he shall see his patient in good surroundings, well lighted with a good light, supplied with proper instruments for necessary examinations, and more especially with attendants who will be able to keep his equipment in order, and assist him where possible in the responsible work which he has to do. Especially in rural districts, the combination of the practitioner and district nurse should be much more intimate than it is now. The present system, by which a practitioner at the end of an exhausting day's work usually sees most of the patients in his surgery, without any regard to his own excessive industrial fatigue, needs modification at once.

Improvement of Hospital Services and Statistics.

As the bulk of expert medical treatment is provided in hospitals, the consideration of the present condition of these institutions and suggestions as to how the hospital services in the country may be improved must form the most important part of this paper. Hospitals were primarily intended for the sick poor, and a perusal of the records of the Hotel Dieu in Paris, where many people were crowded together in very large beds, shows that at one period of our history very little care was given to really efficient treatment. A very interesting life history of Lord Lister by Dr. Wrench,

¹ A paper read before the Society of Medical Officers of Health in London on May 28th, 1920.

showing the fight against enormous odds which he waged 50 years ago to introduce antiseptic surgery in England, shows that the state of the London and provincial hospital then left much to be desired.

Unfortunately, we have not improved as much as we ought. The hospital of to-day is still regarded too much as a charitable institution, and too little as the centre of medical life in the area, in which the largest amount of expert medical work in this country is done. For instance, the ordinary hospital report published to the subscribers each year contains much information as to the financial condition of the institution, and records the generosity of the donors, but the statistics given as to the nature of the work done is very unsatisfactory to the medical officer of health who wishes for exact and reliable information as to the incidence and methods of dealing with disease in his area. This has been specially commented upon by the Royal Commission on Venereal Disease, who suggested that hospitals maintained by voluntary subscriptions should supply more information on these subjects than they do at the present. In the county of West Suffolk, with a population of 116,000, 150 to 200 deaths from cancer occur each year; no details are given in the report of the County Hospital as to the number of such cases dealt with. A house surgeon kindly informed me two years ago that, including the removal of small growths of a suspicious nature, about 30 operations for cancer were performed there every year. As most of the more populous areas are on the edges of this county, and these inhabitants obtain help from general hospitals in other counties, it is quite impossible to ascertain from these sources how many of the cancer cases in the county are dealt with by operation. The house surgeon also stated that about 30 cases were operated on for diseased tonsils and adenoids, and about 80 patients per annum suffered from appendicitis; the population served is probably about 50,000, and the number of beds is nominally 100, of which from 60 to 70 are usually occupied.

Such is the responsible position of the local hospital that it would be reasonable for the Government to require that each hospital should publish a few statistics showing the nature of the work done there, so that the public may know how it fulfils its function as the main sources of supply of the highest forms of medical service in that locality. Some hospitals do not seem to realise this responsibility, and fail to appreciate what may be the plight of the patients whose admission they may be compelled to defer or refuse. In London some acute cases are referred from hospital to hospital in a manner likely to prejudice their recovery and cause them unnecessary suffering, and no responsible person ever knows or seems to concern themselves as to what eventually becomes of them. A practitioner recently told me that two shop-girls in the county for whose admission to a London hospital he had arranged some months ago were still at work and waiting for a bed, one with severe metrorrhagia and uterine fibroids and the other with ovarian disease. We ought to visualise the position of these girls, two only out of an army of sufferers, going to their work day by day, dreading these operations, sometimes hardly able to carry on. It is our duty to improve this system at the earliest possible moment.

General and Special Hospitals.—The Letter System.

The size of the hospitals varies considerably and their distribution in the country is very irregular; 15 counties have one or more with over 200 beds, 20 have some with 100 to 200, eight have hospitals with 50 to 100, seven with 25 to 50, and nine with a smaller number of beds. Specialisation and methods of staffing vary considerably. Considering the two kinds of institution, general and special, and having attended and seen the work done in both, I can affirm that the use of special hospitals shall be discouraged as much as possible, by arranging special departments in the general hospitals. Specialities tend to overlap very considerably, and it is a great advantage for the patient to be transferred to another department in the same institution rather than to be sent somewhere else.

The method of admission to these institutions may be either absolutely free, that is to say, that any person may claim their assistance, or that their services may be given in return for a recommendation from a subscriber known as the subscriber's letter. This usually means that in return for a subscription of £1 ls., a subscriber is entitled to send six persons for out-patient treatment, and for £2 2s., a month or six weeks' residence in the institution is allowed for an in-patient nominated by him. This system varies considerably in different places, and is gradually dying out in the larger London and provincial hospitals. These letters may be handed over to clergymen and other social workers, and they are a source through which patients are admitted to these hospitals, except in certain emergency cases, and even then letters are sometimes asked for whilst the emergency is being dealt with. The letter system is a very bad one; it deprives many people of adequate hospital service, and others who accept it feel there is a certain loss of dignity in doing so. Bishops once had the right to license women to practise midwifery; this function has now been placed in other hands, and it would be very much better for patients to seek the hospital service on their own initiative, or recommended by the doctor, rather than through a recommendation from the clergyman.

Deferred Admissions.

The number of beds in nearly all hospitals is very inadequate, and a selection of the patients has to be made. Most hospitals have a list of deferred admissions. This does not always secure that those cases most in need of treatment are the first to be selected; the protégés of the friends of the hospital may come first, and during the war, when the hospital beds at the disposal of the civil population were seriously cut down, it seemed very dreadful for the maidservant of some wealthy subscriber to be given precedence of admission for some trivial ailment over some unfortunate woman suffering from cancer whose life was at stake. When a serious operation is decided upon it is only humane to get it over as soon as possible, so that patients and their friends may be spared the anxiety of expectation. A long waiting list should be considered a disgrace to us. In some instances visiting medical officers admit patients to the beds, and as they are engaged in some form or other of medical practice their own patients may receive preference. In one case this system has been carried so far that an honorary surgeon in a large hospital has allotted to him about 40 beds, 20 of which are female. Where the patients are supposed to be admitted through a resident officer of the hospital, to be selected especially from the out-patients and other sources, the female beds at any rate are almost entirely filled by women recommended through the surgeon himself either as the result of a private consultation or at the request of some practitioner who has asked him to secure their admission. A country practitioner recently said, "I never send my patients to the local hospital; if they want admission to a hospital, I ask — to deal with the case, and he always takes them into his hospital very soon."

The equipment of hospitals varies very considerably and in many institutions whose names are household words, owing to the lack of money there remains room for considerable improvement. In one important London hospital I recently found that one bathroom had to supply the needs of two large wards for male and female patients, so that it had to be used for each sex on alternative nights. Beds may be placed nearer to each other than is desirable, and there may be a lack of instruments and proper equipment. The staffing varies considerably. Specialisation, first attempted in London hospitals, was not originally carried to the point it is now, but in many large provincial hospitals it is still far from thorough.

The Junior Staff.

It is instructive at this point to note the way in which a man reaches the rank of a full surgeon in a London or provincial medical school hospital. After holding a post as house surgeon he becomes surgical registrar or its equivalent; he has access in this position to all the

records in the hospital, and assists in many of the operations, himself undertaking emergency cases. During this time he is probably fortunate enough to secure a post on the staff of a smaller hospital, where he has the opportunity of improving his surgical work. At the same time, he usually holds an appointment as a demonstrator of anatomy, and the teaching of this subject helps him very much with his other work. After some years of this experience—and usually by this time he is over 30 years of age—he becomes an assistant surgeon to his hospital, a post in which he may have to continue for 10 to 20 years. During this time not nearly enough opportunity is given to such a man to benefit the public by the excellent training which he has had. In some cases he is entirely dependent on his senior for beds, and if he is allotted a few he must consider himself very fortunate indeed. During all these years, before he comes a full surgeon of a hospital, his income is small and his professional expenses, including the heavy rent of consulting-rooms, are very considerable. This system tends to prevent brilliant men without any unearned income from undertaking such work, constituting a very serious loss to the State.

In any reform that takes place in the hospital service, it is absolutely necessary to see that the services of such men are utilised to a much fuller extent than they are now. When a man obtains the post of a full surgeon he is usually well advanced towards middle age, when he hopes to reap the financial reward of his success. And when this comes it limits the amount of time he is able to devote to the hospital, and results in irregular attendance, fixing operations at very inconvenient hours, visits paid late in the day or during meal-times. The other claims on a busy visiting doctor's time interfere with the comfort of patients and other residents in the hospital, and the irregularity is not conducive to first-class work. These disadvantages have been found to be so great that in the London Hospital an experiment is being made by which some of the major surgery is left in the hands of resident officers, who are paid a substantial salary for their work, and I am informed that similar conditions prevail in the hospitals in Paris. In county hospitals and in large towns there may be some attempt at specialisation, but it varies considerably; owing to the limited population and the almost exclusively industrial character of the area covered by these institutions it is often impossible for a man to make a livelihood by working in the neighbourhood as a pure specialist. The staff are thus nearly all more or less, and some entirely, engaged as general practitioners. As most of those engaged in general practice are chosen by seniority their practices are as a rule very large, and as they are accustomed in their ordinary work to see patients hurriedly, this overpressure, added to their want of leisure, prevents them from reading modern literature, or attending other institutions or meetings of learned societies where they may compare their work with that of others. A mental attitude is thus developed which is not conducive to the critical atmosphere necessary for careful diagnosis or the application of skilled technique, so that their work might with advantage be supplemented by help from the staff of a teaching hospital.

Major Surgery in the Cottage Hospital.

At the present moment a hospital is usually a watertight compartment. As a rule, it must either take a case or leave it absolutely unprovided for; so that a surgeon with very limited experience in dealing with difficult cases may feel that it is his duty to perform some important major operation, or, on the other hand, to refrain from doing something which might be a material help to the patient, because he is unable to command better services. It has been suggested that each smaller hospital shall be related to a larger institution, to which it would be possible, automatically, to transfer cases requiring special skill, and the sooner this scheme is developed the better.

I recently had the opportunity of seeing a small cottage hospital in a small town, 10 miles from a large centre with a well-equipped hospital; it had four beds and faced a very narrow street, along which ran an open

channel, into which, I am informed, household slops are sometimes emptied. The operating theatre consisted of a covered-in yard, and the house was supplied with a cesspool drainage. A local practitioner, who showed me round, informed me that such operations as prostatectomy were intended to be done there. At the present moment the only type of work done by medical men which is inspected is vaccination; and from the statements made by many public vaccinators it would appear that dissatisfaction is not infrequently expressed by the central authority at the way in which this simple operation is performed. It sometimes happens that in one of these cottage hospitals a practitioner with limited experience may perform a very serious operation which at present it is no one's duty to criticise.

I had the opportunity of seeing an elbow-joint which had been excised by a practitioner recently qualified, and which he had sent to an old teacher as a proof of his skill. This joint was apparently healthy, and ought not to have been removed. The patient probably had from 30 to 40 years' prospect of life, and to be compelled to spend this time with one arm like a flail must have interfered considerably with his working capacity. The only qualification this surgeon had for holding this hospital appointment was that he had recently purchased a practice or partnership in the neighbourhood. It seems reasonable that serious major operations, except in cases of extreme emergency, should not be done in a cottage hospital, and if it is considered desirable for major operations to be done there at all, the skilled and well-trained surgeons of this country should ask for, and cheerfully submit to a system of inspection which might do something to prevent operations under such conditions as those described above. As all our principal surgeons do most of their operations in public they are already exposed to a very thorough system of inspection, so that they need hardly be conscious that it was taking place.

There is increased and growing discontent on the part of the general practitioner, because he is unable to refer his cases to some practitioner engaged exclusively in consulting practice, as the only sources of consultation available to many of them are the services provided by local hospitals. Some time ago a practitioner complained that he had sent a patient with what he considered to be a cancer of the cervix to a local hospital for operation. The patient who was sent was discharged very soon, and was indignant with him for sending her there, because the hospital doctor had told her there was nothing the matter with her. Some months later she consulted her doctor again with an inoperable growth. He felt that both he and his patient were entitled to have had an opportunity of consulting a specialist, who should have decided the necessity for any operation that might have been necessary in such a case.

We may compare such procedure with that which takes place in enforcing the law, where a prisoner is only condemned to death after being dealt with by a judge who receives a salary of £5000 a year, is chosen as a master of his craft, and is provided with a considerable amount of assistance before arriving at his decision. And it has been suggested that if judges go on circuit to deal with such cases doctors should do the same.

An Interesting Experiment.

A very interesting experiment has recently been made in West Suffolk, due largely to the public spirit of the county director of the Red Cross. A distinguished consulting surgeon comes into the district at frequent intervals to operate on discharged and injured soldiers in the local hospital. This experiment appears to have been an unqualified success, and the medical officer of health suggested that a similar scheme might with advantage be adopted for other cases. During the war, when working on medical boards, I saw a number of disabled men who were brought in from the country for medical examination labelled as cripples, who, in some instances, possessed no working capacity whatever. A great deal might have been done for some of them by proper treatment, so I recently caused a census to be made with a view to ascertaining the

number of cripples in the county (population about 116,000), and these are some of the results. Of 127 cases reported on, 35 were said to have had some treatment at local hospitals, 22 at special hospitals in London. Many of them (70) had had no special treatment at all. Some cases unable to travel to London as often as necessary had to discontinue treatment so that any benefit received was entirely lost. In one case this happened after a mangle and wardrobe had been sold to defray the expenses.

This scheme was brought to the notice of the local branch of the British Medical Association, who expressed themselves enthusiastically in favour of it. At present some discussion arises as to what type of consultant shall be employed in working such a scheme. Members of the hospital staff suggest that he should be a senior consultant attached to a large London hospital. The situation would be met by employing an experienced member of the junior staff from a teaching school hospital, but in any case the principle is admitted that the services of the present staff do not entirely meet the needs of the district, and there is no provision for anything else. It is instructive to note that in one district in England where there is a fairly large local hospital three of the wives of members of the staff within recent years have required major operations, and although their husband's colleagues are expected to do such work in the local hospital, they were all operated upon by London surgeons. Without desiring to restrict the freedom of any patient to be operated upon by whosoever he wishes, provided the surgeon is a qualified practitioner, it cannot be too strongly urged that patients needing skilled examination or operation residing in any part of the country whatever should be given the opportunity of being examined and operated upon by a master of his craft. This can only be done by mobilising to the uttermost the services of the junior consultants, who would be able to render excellent services if they were only given the opportunity. We may again emphasise the point that such men are appointed by responsible hospital committees to give their services during the absence of their chiefs, and that any moment they may be called upon by death or accident to succeed the surgeon whom they are called upon to represent. A junior consultant to-day may literally become a senior to-morrow.

One of the causes of overcrowding in the large medical school hospitals is that many practitioners are recognising the disadvantages of local consultations, and are sending their patients to larger institutions rather than to the local hospital, causing a considerable amount of overcrowding. This could to some extent be avoided by sending well-trained consulting surgeons to consult and operate in the country.

A Survey of All the Hospitals.

It is therefore suggested that there should be a survey of all the hospitals in the country, that the smaller ones should become casualty stations, that some of those of a large size should have their staffs strengthened by a periodical visit from the consulting staff from a teaching school hospital, and that no attempt should be made for any supposed vested interests to exclude this valuable help. There are, especially in the North of England and in the other manufacturing centres, populous districts in which the inhabitants are chiefly working-class people, with a few well-to-do residents. The latter would probably avail themselves of the services of a consultant from London, or a neighbouring teaching school; most of the work-people receive specialised treatment at the hospital. Such a district is incapable of providing an income for a local specialist. Many of the hospitals in such areas are of appreciable size, and they ought without delay to reinforce their staffs from the nearest teaching school hospital, as specialist treatment is absolutely necessary to keep such an amount of working capacity at its maximum of efficiency. General practitioners are more and more anxious to avail themselves of really skilled help and are objecting to being provided with anything else, as they realise that the exacting life they lead and the hurried manner in which they have to deal with their

patients does not afford them proper opportunities of doing this work themselves. It is specially desirable at this moment to emphasise this point, as the Ministry of Health are appointing a number of consultants to work the Insurance Act. These men, to be trusted as they should be, must be engaged in consulting practice, must be associated with the work of teaching school hospitals, and must be able to prove to those who employ them that they are keeping themselves up to date.

A Local Authority Hospital Service.

The outlook of medical service has been altered entirely by improving facilities for transport, and it is quite possible now to remove a patient 20 or 30 miles in a well-constructed ambulance without any inconvenience. In the same way, specialists are able to travel a very considerable distance to visit centres for the purpose of seeing patients, or performing operations in a way which was impossible when most of the hospitals were built. In addition to general hospital services, as supplied by local committees, there are Poor-law infirmaries, where the expert work is usually left to a medical superintendent, who has to administer a large institution and devote his energies to all types of cases. Although there are in this service a few men who do wonders in spite of these difficulties, this method of organisation is not capable of providing what is required. As some of the infirmaries in London south of the Thames have to serve the area largely as general hospitals, the question of re-staffing those institutions is a somewhat urgent one. They would form an excellent nucleus for a local authority hospital service. Local authorities have provided hospitals for infectious diseases. In the larger centres these are, as a rule, well administered, enjoy the confidence of the public, and afford an excellent reason for the hospital services of the State being undertaken by large local authorities; on the other hand, the administration in some of the smaller institutions leaves much to be desired. For instance, a county medical officer some time ago visited a small fever hospital where the nursing of the patients was left to the wife of an employee of the district council, who had to do such work as emptying the earth-closets. Although this woman had had some nursing experience, such a combination of persons and functions was not likely to attract the best type of officer. Some of the patients slept together in double beds, no easy chairs were provided, and patients convalescing from diphtheria were compelled to sit on benches without any backs. The food was stored in the bathroom and in the bath; the same tongue-depressor was used for examining a series of throats; no overalls were provided for the doctor or nurse; and there was no means of washing the visiting doctor's hands. This carries us back to the day when such institutions were regarded as a means of protecting the public, and the patient's recovery was quite a secondary matter. The remedy for such conditions would be a system of proper inspection of these institutions and the closing of many of them. This would be only fair, as it is not infrequent for patients to enter isolation hospitals under pressure, contrary to the wishes of their friends, and they ought to be provided with a proper service. This work could be carried on in central hospitals, the patients being moved there by motor ambulances. A larger institution is desirable for efficient and economical working, and provision should at the same time be made, where necessary, for the conveyance of the friends of those on the danger list, and sometimes for their accommodation in the institution.

In addition, health authorities to some extent fill in the wide gaps left in our hospital system by providing clinics and special treatment for diseases such as tuberculosis, venereal diseases, maternal and infantile disorders, diseased tonsils and adenoids, refraction work, and so forth. In many instances this help is provided through whole-time officers; it is, as a rule, very good, one advantage being that the medical officer of health is able to secure that the services provided are up to date. This limited ad hoc method of meeting the

situation is unsatisfactory. It would be much better to deal with the whole community through one large series of specialised institutions, the voluntary hospital maintaining its place in the system. It is absolutely unjustifiable, except on the grounds of pseudo economy, that women and children who constitute the largest number of patients of the ordinary doctor should be excluded from the benefits of the Insurance Acts. This, and the gross overcrowding and long waitinglists of the gynæcological departments, the absence of skilled treatment for abortions and other female ailments, and the great lack of maternity beds in general hospitals, accentuate the difficulties of local authorities in dealing with the situation. More help is needed for hospital committees, especially in such matters as the provision of new buildings, reconstruction, and developments. These details are sometimes dealt with by a committee without any expert assistance; this may prevent the subscribers' money being spent to the best advantage, and it would be to the benefit of the public if the situation were more widely recognised. It would be of great assistance to all those who have to administer such institutions if the Ministry of Health would provide a record office where a full description of all up-to-date institutions can be found, placed in the charge of some intelligent person who would be able, at short notice, to produce photographs, plans, and specifications of any new institutions that may be erected in any part of the world.

I had the opportunity of visiting a new hospital at Toronto six years ago, where it was the boast of the management that they had put into it everything that was good in any other institution in America or Europe, and they assured me it was exceedingly difficult for them to obtain the necessary information. One innovation appeared to be of great value. Instead of admitting accidents and emergencies at all hours of the day or night into the general ward and disturbing the rest of the hospital in consequence, they had a unit of about 30 beds with a separate theatre provided to deal with such cases, and this was found to be extremely valuable.

The Ancillary Services.

The provision of expert services would be incomplete without noticing the valuable help rendered by nurses and the women workers in nursing, massage, electrical and other departments, services which have made enormous strides during the war. Such services should be at the disposal of any general practitioner and patient that may need them. The utilisation of the service of the general practitioner in general hospitals needs careful consideration. It should be done as much as possible, though there are great practical difficulties. The general practitioner in the interests of the public ought not to undertake major surgical operations without expert medical assistance, but he ought to take part in this and other hospital work. The best solution of this problem would be the establishment of a number of out-patient clinics where this closer co-operation could be commenced. In small towns every medical practitioner ought to be admitted to the hospital staff as a means of preventing the curious anomalies that sometimes exist now. There should be beds where the general practitioner can deal with his patients in institutions, although we must not forget that if this work were provided for on a large scale some uniform and agreed system of dieting would have to be arranged. It may be said that all sections of the public seem to have a weakness for the irregular practitioner. One of the best methods of dealing with this matter is to make the public realise the very unsatisfactory nature of the services they render. Unfortunately, orthodox practitioners either from lack of opportunity or want of appreciation have not explored sufficiently such subjects as remedial exercises, massage, and manipulation, which are capable of rendering patients great assistance in keeping well and in curing their disease. In consequence, this sort of treatment has got chiefly into the hands of quacks who, with the imposing consulting-rooms and much ritual have undoubtedly gained the confidence of some of their patients by treatment which could have been

provided to much better advantage by orthodox practitioners. Although in many instances the quack is a serious menace to public health, he is more difficult to deal with because he has been allowed in this way to stray into legitimate fields of treatment.

I have especially avoided going into too much detail, and have left the financial side of these questions severely alone, but wish to emphasise the necessity of providing a system to supply expert medical service of the best type to everyone needing it, as something that is absolutely necessary to maintain that working capacity, rather than as an act of charity. Although not recorded in any book, or capable of support by an array of figures available at this moment, we may be sure that there is a considerable amount of preventable and unnecessary suffering, premature death, and loss of working capacity and money, due to the want of organisation of our hospital system. We have learnt a great deal in the war which may be applied to these present problems. Such members of the public and the medical profession who study these questions (and they are rapidly increasing in number) are profoundly dissatisfied with the present state of things. The time is therefore ripe for reform, and it is for the medical expert to indicate clearly on what lines it may be most effectively carried out.

MEDICINE AND THE LAW.

The Proprietary Medicines Bill.

THE general policy of this Bill was explained and commented on in a leading article in THE LANCET last week, and it will have been gathered by readers that, except in the case of certain diseases, alleged remedies for which are not to be sold at all, it orders the registration of proprietary medicines and appliances, with full particulars of the articles in question. It does not appear to intend that the registration should in any case be refused for such a reason as that a medicine is not likely to produce the therapeutic effects claimed for it, but seems to contemplate the registration taking place if the prescribed regulations as to application for registration are complied with. The Minister of Health may, however, make regulations under Section 5 (c) "For prescribing the causes for which and the manner in which a registered owner may be removed from the register." In this and other respects the effect of the Bill cannot be properly estimated until it is passed, and then not until the regulations to be made under it have been acquiesced in by Parliament. Attention is here called to some of the principal provisions of the Bill as introduced and printed.

Sections 1, 4, 6, and 7 order the registration of proprietary medicines and appliances, and Section 5 defines in detail the formation and maintenance of the register, which is to be the subject of regulations. Two important sections of the Bill are, however, independent of regulations. The first of these which, it is proposed, should come into force six months after the commencement of the Act, declares that it shall not be lawful "for any person to sell or to offer or advertise for sale any medicine or surgical appliance of any kind whatsoever purporting or stated directly or by implication to be effective for the prevention, cure, or relief of any of the diseases or infirmities mentioned in the schedule to this Act." The schedule, which can be enlarged by regulation of the Minister, at present contains cancer, consumption, lupus, deafness, fits, epilepsy, amenorrhœa, and other diseases peculiar to women, diabetes, paralysis, locomotor ataxy, Bright's disease, and rupture. It is to be noted that the proprietary medicines and appliances here forbidden to be sold include not only those where the owners propose to "cure" a scheduled disease, but also those which are put forward as effective to "prevent" or to "relieve" it. This makes the section extremely comprehensive, and it is one which will, no doubt, be criticised as such. The occasion, however, is not one for half measures, and an easy means for continuing the trade in various ineffective or dangerous compounds or articles would be provided if their owners

were merely prohibited from pretending to "cure" such diseases as those in the schedule.

The limiting words quoted above may be noted in connexion with the question of what medicines and appliances, if "proprietary," must be registered. Section 10, which contains the interpretation of expressions used in the Bill, defines "medicine" as including any drug, preparation, or compound to be used externally or internally for "the prevention, cure, or relief of any malady, ailment, infirmity, or disorder affecting human beings." It defines, on the other hand, a proprietary surgical appliance as "any instrument or contrivance of a medical or surgical nature which is recommended to the public by advertisement, label or otherwise in writing, as of use for curative purposes, and which is sold under a trade-name or a trade-mark to the use of which any person has or claims or purports to have an exclusive right, or for the making or selling of which any person has or claims or purports to have an exclusive right." It will be seen that unless a surgical appliance comes within Section 2, when its sale is forbidden, or is advertised as curing or tending to cure (which is presumably the meaning of "for curative purposes"), when it must be registered, it is not a "proprietary surgical appliance" within the meaning of the Bill. It seems clear that this will leave untrammelled the trade in many useful appliances, the manufacturers of which make no promises incapable of fulfilment, and have built up businesses to which none can reasonably object. The definition or interpretation, however, of the word medicine, quoted above, appears to introduce some possibility of doubt and difficulty, in that it may not always be plain whether that for which cure or relief is advertised is to be classified as a "malady, ailment, infirmity, or disorder." Drugs, for example, advertised as having the effect of making their consumers fatter or thinner can hardly be said to promise the relief of a malady in so far as they are offered to men or women dissatisfied with their physical attractions. Presumably, however, they may bring themselves within the contemplated law if they refer specifically to obesity or emaciation arising from disease, and hold out in their advertisements hopes for its cure or relief.

The other section referred to as not to be affected by regulations forbids absolutely the advertising of proprietary medicines or surgical appliances by the use of those devices which have become familiar in the past, and which, no doubt, have been found profitable by the vendors of useless or pernicious nostrums. The statement that the article advertised is recommended by a medical practitioner without full particulars of his identity is forbidden, *inter alia*, as is a false statement or suggestion that a medical practitioner first discovered, invented, or compounded the article advertised. It may be noted that the protection of the legitimate sale of medicines is provided for by Section 9 in the following terms: "Nothing in this Act shall operate to render unlawful the sale of any medicine or appliance to or for the use of any person in accordance with a prescription given in the case of that person by a duly qualified medical or dental practitioner." This seems to suggest that the sale of a medicine, not given under a prescription in the case of the person who will use it, will in future be unlawful. The practice of using prescriptions given to other persons exists, and is objectionable no doubt, and it is right that it should not be specifically protected. It must not, however, be taken as forbidden by the words quoted. The compound ordered in a prescription may be a medicine as defined in the Bill, but it can hardly become a "proprietary medicine" either according to the definition of "proprietary" or in the ordinary meaning of the word, merely because it is sold to a person for whom the prescription was not intended.

It will be interesting to watch the fate of some of the sections of the Bill when it comes to be discussed in detail in the House of Commons, but the Ministry of Health and the public will alike deserve congratulation if the measure passes without mutilation or destructive amendment.

An Ignorant Maternity Nurse.

At a recent inquest at Hackney on the body of the wife of a shipping clerk it was proved that the cause of death was blood poisoning following upon the confinement of the deceased. The medical man who had attended the deceased stated that he had found that the monthly nurse who had been engaged to attend the case had a finger in a septic condition, and he had accordingly dismissed her. He added that the woman in question had admitted to him that she had never passed any examination, and that she did not even know the meaning of the word "antiseptic." The coroner expressed surprise at such a person being employed and warned her upon her conduct, which, if she continued to attend such cases, might place her in a very serious position. He recorded a verdict of "Accidental death." If, as is to be gathered from the report of the case, the coroner was sitting alone, it would appear to have been one in which a jury might well have been summoned, and that the "nurse" was lucky in not having to face trial for manslaughter. The Nurses Registration Act, 1919, should, at any rate in future, operate to prevent such a person from securing registration under its provisions for an "existing nurse's" registration; to enable such a person to be removed from the register if upon it; or to prevent such a person, not being on the register, from calling herself or pretending to be a registered nurse. It will not prevent anyone from employing as a nurse in childbirth an ignorant, dirty, and unqualified person. It is gathered from the reports of the inquest above referred to that the "nurse" was engaged to act under a medical man and not as a midwife.

Prohibited Milk.

At Taunton County-Court a local dairyman recently brought an action against the town council for £100 damages for loss caused by the order which was enforced from Jan. 6th to Jan. 31st, prohibiting the admission of his milk into Taunton. Last November and December enteric fever broke out in the town, and it was discovered that out of 11 cases of the disease four had obtained their milk from the same retailer. This tradesman had his milk from three different sources, the plaintiff's dairy being one of them. Analysis of the milk showed that although there was no direct proof that the milk was a source of the disease, there was "gross contamination" from a dirt point of view, and consequently there was reasonable ground for enforcing the order. His honour (Judge the Honourable W. B. Lindley) dismissed the plaintiff's claim with costs, stating, in delivering judgment, that the order was made for the protection of the public, and prompt action was necessary by the council. This body acted upon the advice of the medical officer of health, who had formed his opinion with reasonable and sufficient care and evidence.

HOUSING NOTES.

The Conservation of Hygiene.

THE Ministry of Health is already laying plans against the obvious danger of degradation which the new hygienically-constructed houses will have to face. The cynic might be tempted to sneer, "First build your house." He would be wrong in doing so, for, as has been shown in a recent number of *Housing*,¹ there is already much slum property which might be redeemed to afford decent living conditions by proper management. At Fulham, for example, there has been no rebuilding at all. Some women, trained on the lines laid down by Miss Octavia Hill, began to manage a few houses purchased by a private owner in this area about eight years ago, and the number has gradually increased to 60 or 70. The houses were shockingly overcrowded when first purchased by the present owner, with the sanitary fittings destroyed, the walls, ceilings, and floors badly damaged, windows broken and woodwork gone. There is a marked difference between the

¹ *Housing*, July 19th, 1920.

condition of recently acquired houses and that of others in the same neighbourhood which have been carefully supervised for six to eight years. From all this it emerges that the manager of property should be the person who receives the rent, and that he or she—preferably, it seems, she—should be a trained social worker, able to appreciate the needs and difficulties of the tenant without forgetting that the landlord must receive his interest. If the work is well done the manager will be popular, the tenants will become more self-respecting and therefore better tenants, while a good environment will be created for the social education of young householders, whose living habits are unformed. It is clear that a manager of property has a very responsible post. In order that suitable officers may be found a reasonable salary must be offered. The city of Amsterdam has been paying its chief woman manager a salary rising from £350 to £550. Her assistants, when fully trained, receive up to £291. These do not seem tempting salaries in our days, but the scheme is expensive. The municipality of Amsterdam, however, believes that the money so spent brings in a good return. Will English authorities be equally far-seeing?

The Myth of Loftiness.

The substitution of the kata-thermometer for the carbonic-acid index of ventilation has made necessary a complete revision of standards for the architecture of living rooms. This is brought out in an interesting manner in a short article by S. W. W.,² who effectually

² Ibid., June 21st, 1920.

destroys our faith in the lofty ceiling. It is less important in view of modern knowledge to have high walls than to have high windows, and cubic space is best obtained by having a large floor area, so that the infections resident in the respiratory tract are less liable to pass from host to host.

The Output of Houses.

Progress in new construction is not rapid. It may be doubted whether we have yet reached a rate of output commensurate with the normal growth of population. Members of the Government have been in conference with representatives of the building trade, though no agreement appears to have been reached as yet. We believe that both sides are sincerely concerned for the public welfare and that such conferences must eventually bear fruit. The Government must realise, however, that with raw materials at their present price building will not progress rapidly, however many recruits are drafted into the industry. Increasing subsidies will some day become a serious drain upon the public purse. Dr. Addison stated in the House of Commons on July 15th that the high prices would be met by using alternative methods of construction. This is no real remedy. Many items such as lead piping will be common to all kinds of construction, and if a new wall material becomes popular experience shows that it will soon become expensive in proportion to its utility. The time will come when the price of building materials must be controlled as food prices were controlled during the war, and for the same reasons.

* There were no returns from the station at Golden Lane in London during February owing to the gauge being under repair, and there were no returns from Stirling for both February and March.

"Tar" includes all matter insoluble in water but soluble in CS₂. "Carbonaceous" includes all combustible matter insoluble in water and in CS₂. "Insoluble ash" includes all earthy matter, fuel, ash, &c. One metric ton per sq. kilometre is equivalent to: (a) Approx. 9lb. per acre; (b) 2.56 English tons per sq. mile; (c) 1 g. per sq. metre; (d) 1/1000 mm. of rainfall.

The personnel of public health authorities concerned in the supervision of these examinations and of the analytical work involved remains the same as published in previous tables. The analyses of the rain and deposit caught in the gauge at the Meteorological Office are made in THE LANCET Laboratory.

"Audi alteram partem."

THE PHARMACIST AND THE PROPRIETARY MEDICINES BILL.

To the Editor of THE LANCET.

SIR,—In approaching the Proprietary Medicines Bill from the standpoint of the pharmacist, I must first of all express the regret that one of the most brilliant members of the pharmaceutical profession of our time, and the one whose patient work perhaps did more than that of any other man to enlighten the public mind on the follies of quackery, has not lived to see his efforts so near fruition. I refer to the late Lieutenant-Colonel E. F. Harrison, who before working himself to death in order to find means of protection for our troops against the German poison gases, devoted years of his life to unravelling the secrets of secret remedies and so demonstrating how the vast majority of the population of this country was being fooled by a handful of nostrum mongers. *Omne ignotum pro magnifico*. After Harrison had finished his labours there was little left to be known about the secrets of the quacks.

It will be understood that these references to quackery do not embrace every maker and vendor of proprietary medicines; probably scores of proprietary articles could be enumerated which not only do not merit condemnation, but are almost as good as they are claimed to be. The class of compound I have especially in mind in making this reservation is that which depends for its vogue on some special manipulative method which makes the medicine superior in one way or another to others of its kind, and is as different from the offensively advertised "cure-all" as chalk is from cheese.

If proprietary medicines had been confined to the better type, or even to such as are made in almost every pharmacy in the country, it is possible that restrictive legislation would not have been needed. What made the business an offence to public decency was the long and rapidly lengthening list of worthless mixtures, pills, and salves, foisted on a credulous people by men of the get-rich-quick type, who knew nothing and cared nothing about the properties of drugs so long as they brought grist to the mill. As I read the provisions of the Bill, there is nothing in it to prevent any man from turning an honest penny, but if it does not prevent the public from being fooled it will fail in its purpose.

Coming to the details of the measure as they affect the conduct of the maker or vendor of proprietary medicines, the most noteworthy provision is that which prohibits the sale of alleged cures for cancer, consumption, deafness, fits, epilepsy, amenorrhœa and other diseases peculiar to women, diabetes, paralysis, locomotor ataxy, and rupture. I have yet to meet the pharmacist who would deny that it is wrong to sell "cures" for incurable diseases, and if that description of the object of the provision is hardly complete, I hasten to add that I have met no pharmacists who would not admit the justice of putting a stop to the exploitation of persons suffering from any one of these diseases. Next in importance comes the provision that the composition of proprietary medicines must be disclosed in confidence to the Registrar in a Government department. That the notorious quack will find many specious reasons why he should not do this there is not the least doubt, but with him we are not concerned. Will the pharmacist object? I do not think so. Some years ago, following a new interpretation of one of the sections of the Medicine Stamp Act, practically all the pharmacists in practice in Great Britain disclosed some of their most prized formulæ, and had them printed in a book that ran into thousands of copies. Is it likely that a pharmacist who will publish the names of the ingredients of his compounds for all the world to see will object to have them placed in the hidden archives of the Ministry of Health?

There is, however, one provision to which pharmacists may possibly take exception—namely, that which makes

it an offence for anyone selling a proprietary medicine to enclose within the wrapper an advertisement of another proprietary medicine. In whose interest this is made an offence I do not know, but it is certainly not in the interests of the public, since we find nothing in the Bill to prohibit the advertising of proprietary medicines in the public press, with the exception of medicines for the diseases specifically named. As a matter of fact, this clause has already been withdrawn. Another objection which pharmacists may raise is that the Minister should not have the power to add to the schedule of diseases remedies for which may not be sold.

Finally, it should be remembered that proprietary medicines are almost as old as the hills, and that reasons against the interference with the immemorial way of life must be heard with patience. A lesson may be learned from the Australian Royal Commission, on the results of whose inquiry into secret medicines the law affecting their sale in Australia was based. This Commission made a strong point of the fact that while in England makers of feeding-stuffs for animals and manures for the ground must disclose the composition of these articles, the English law allowed human beings, whether babies or adults, to be dosed with secret compounds. Unless it is proved that cattle and turnips are more precious than human lives, an answer will have to be found to the remonstrance.

I am, Sir, yours faithfully,

PHARMACEUTICUS.

August 10th, 1920.

THE TREATMENT OF ACUTE INFECTION OF THE KNEE-JOINT BY ACTIVE MOVEMENT.

To the Editor of THE LANCET.

SIR,—The allusion in your annotation of July 10th (p. 81) to this method of treatment reminds me of a series of cases which I treated when in France. Willems's method, in my hands, gave only a small measure of success, because I was unable to persuade the patients to carry out the movements unaided. I therefore designed a contrivance which, by means of a mobile splint and counter-weights, overcame the force of gravity. By this the movements were made as easy as possible, and the initial pain and weakness did little to hinder them.¹ The immediate effect was striking. After the first day or two pain was definitely eased by active movement, tracking appeared to be prevented, and the vascularity of the limb was maintained. During treatment the joint secretion tended in two or three weeks to become clear, resembling normal synovial fluid, and the wounds rapidly granulated and healed.

I ascribe the beneficial effect not only to the mechanical expression of pus by the movements, but also to the maintenance of a good blood-supply. In a part functionally at rest the blood tends to stagnate, especially in the lower extremity, where venous return is largely dependent upon muscular activity. Given a good blood-supply, a synovial secretion more potent in its bactericidal property is reasonably to be expected. This property appears to be maintained, provided that the fluid is prevented from stagnation by arthrotomy in the more severe cases, or by aspiration in the milder.

Several of my cases bore a marked resemblance to that published by Dr. F. B. Lund. Of a series of 23 septic knee-joints which I treated in this way, 11 obtained good mobile joints; 1 only was amputated, and that for other reasons. Though in civil practice we are not often confronted with the problem of the infected knee, I have had a few instances where the principles evolved, as the outcome of experience gathered during the war, have been further established. For example, a girl of 6 was admitted under my care into King's College Hospital, having run a rusty needle into her knee-joint. In three days the joint had become distended with a fluid which was found on aspiration and examination to be rich in pus cells and staphylococci. Three aspirations, combined with active move-

¹ A New Method of Treatment for Suppurative Arthritis of the Knee-joint, British Journal of Surgery, April, 1919.

ments, brought about complete resolution in three weeks, and she left hospital walking perfectly. Such a case would, I think, undoubtedly have been treated by the majority of surgeons in pre-war days by wide incisions and drainage-tubes placed in the synovial cavity. The results of such treatment are too well known to require description.

The rarer form of gonorrhoeal arthritis—namely, synovitis with effusion—I have recently been treating in a similar fashion by aspiration with active movements. The result has been stimulating to further endeavours.

I am, Sir, yours faithfully,

JOHN EVERIDGE.

Upper Wimpole-street, W., August 3rd, 1920.

EMBOLIC ANEURYSM OF PERIPHERAL ARTERIES.

To the Editor of THE LANCET.

SIR.—In your interesting annotation dealing with the communication by Mr. Douglas K. Adams on Embolic Aneurysm of Peripheral Arteries, which appeared in the *Glasgow Medical Journal*, you refer to the critical review on bacterial endocarditis by Irving Simons, published in the *Quarterly Journal of Medicine* for April, 1914, as giving "a list of the recorded cases of embolic aneurysms." This list is not, of course, confined to "peripheral" aneurysms; it is intended to include those found in other vessels, such as the branches of the coeliac axis and the renal and cerebral arteries. The list is prefaced by the remark: "The distribution of embolic aneurysms is of extreme importance," and in a note following his table the writer says: "These cases are all that I have been able to find in the literature."

I have always regarded the omission from Simons's review of any reference to aneurysm of the coronary arteries of the heart as a serious flaw in his admirable contribution to our knowledge of bacterial affections of the endocardium. In the *British Medical Journal* of Feb. 2nd, 1901, in putting on record two cases of embolic aneurysm of the coronary arteries of the heart, associated with infective endocarditis, I gave a list of all the cases of aneurysm of those vessels which I had been able to collect from the literature. Although it is not likely that this list was a complete one, it dealt with 24 instances, including my own two, the earliest of these being that which was put on record by Bougon in 1812. I was able to read the original account of 18 of these, and I found that in six of them infective endocarditis was seen on autopsy. This is, of course, strong presumptive evidence that the aneurysms were embolic, and in discussing the remaining 12 cases I gave what I considered good reasons for thinking that most of them also were due to this cause.

Subacute infective endocarditis is an affection which appears to be on the increase. Its frequency during the war was very striking and it may be that its continued frequency is an aftermath of war. I would urge that every opportunity be taken by those who are engaged in making autopsies in cases of infective endocarditis to include a careful examination of the coronary arteries for embolism. If the common cause of aneurysm of the coronaries in infective endocarditis is indeed embolism, the proof of this will be found not in the demonstration of an embolus in association with the aneurysm, for an embolus may well have disappeared after the infection of the arterial wall has led to softening and dilatation, but in the frequency of coronary embolism being shown to be greater than is usually supposed. It is a remarkable coincidence that the two cases of coronary aneurysm I put on record were seen in autopsies done by me on the same day, and that the next autopsy I performed was also on a case of infective endocarditis in which the patient had died suddenly, and in which I found both coronary arteries plugged by detached vegetations.

One of the points I desired to emphasise in my paper of 1901 was the probability of aneurysms of the coronary arteries "sharing the peculiarity of aneurysms on small vessels elsewhere in being embolic in origin."

I am, Sir, yours faithfully,

Leeds, August 9th, 1920.

T. WARDROP GRIFFITH.

STANDARD ARTIFICIAL LIMBS.

To the Editor of THE LANCET.

SIR,—I notice in your issue of July 31st that you have published an article on Standard Artificial Limbs, and I am surprised that the information you have received has not any reference to the services rendered to the Ministry of Pensions by the British Artificial Limb Makers' Association.

Throughout the whole of the work of devising standard artificial limbs a large proportion of the research and experience necessary to arrive at satisfactory solutions of difficult problems devolved upon the British Artificial Limb Makers' Association, and Sir Charles Kenderdine has acknowledged at more than one meeting of the Advisory Council to the Ministry to what a large extent the work has been indebted to the Association for assistance and suggestions. The Limb Makers have combined to place their experience at the disposal of the Ministry to arrive at the most satisfactory forms of limb for standardisation, and I shall feel greatly obliged if you will accord the same publicity to this letter as to the article referred to.

I am, Sir, yours faithfully,

W. R. GROSSMITH,

Honorary Secretary, British Artificial Limb Makers' Association.

12, Burleigh-street, London, W.C. 2, August 6th, 1920.

URBAN VITAL STATISTICS.

(Week ended August 7th, 1920.)

English and Welsh Towns.—In the 96 English and Welsh towns, with an aggregate civil population estimated at nearly 18 million persons, the annual rate of mortality, which had been 9.9, 9.8, and 9.9 in the three preceding weeks, fell last week to 9.6 per 1000. In London, with a population of nearly 4½ million persons, the annual death-rate was 9.1, or 0.4 per 1000 below that recorded in the previous week, while among the remaining towns the rates ranged from 2.7 in Enfield, 4.3 in Ealing, and 4.9 in Walthamstow, to 15.4 in Bury, 16.3 in Stockton-on-Tees, and 17.2 in Hastings. The principal epidemic diseases caused 163 deaths, which corresponded to an annual rate of 0.5 per 1000, and comprised 87 from infantile diarrhoea, 28 from diphtheria, 22 from measles, 17 from whooping-cough, 9 from scarlet fever, and 5 from enteric fever. Measles caused a death-rate of 2.0 in Aberdare, but the mortality from the remaining diseases showed no marked excess in any of the towns. There were 2022 cases of scarlet fever and 1469 of diphtheria under treatment in the Metropolitan Asylums Hospitals and the London Fever Hospital, against 1956 and 1481 respectively at the end of the previous week. The causes of 34 of the deaths in the 96 towns were uncertified, of which 8 were registered in Birmingham and 4 in Hull.

Scotch Towns.—In the 16 largest Scotch towns, with an aggregate population estimated at nearly 2½ million persons, the annual rate of mortality, which had been 11.1, 11.6, and 11.2 in the three preceding weeks, fell to 11.1 per 1000. The 256 deaths in Glasgow corresponded to an annual rate of 11.1 per 1000, and included 8 from infantile diarrhoea, and 2 each from small-pox, measles, diphtheria, and whooping-cough. The 56 deaths in Edinburgh were equal to a rate of 8.6 per 1000, and included 1 from infantile diarrhoea.

Irish Towns.—The 107 deaths in Dublin corresponded to an annual rate of 13.4 per 1000, or the same as that recorded in the previous week, and included 4 from whooping-cough, 3 from infantile diarrhoea, and 1 each from enteric fever and diphtheria. The 95 deaths in Belfast were equal to a rate of 12.4 per 1000, and included 10 from infantile diarrhoea, 2 from scarlet fever, and 1 each from enteric fever, measles, and whooping-cough.

ROYAL COLLEGE OF PHYSICIANS, EDINBURGH: DR. JESSIE MACGREGOR PRIZE.—The trustees of the Dr. Jessie Macgregor Prize announce the award, for the present triennial period, to Miss Lucy Davis Cripps, M.B.E., M.B., Ch.B. Edin., for her work on tetra. The prize, which is open to medical women graduates of Edinburgh University or to women who have taken the triple qualification, is given to the applicant who presents the best record of original work in the science of Medicine, done not earlier than three years prior to the date of the award.

The Services.

ROYAL ARMY MEDICAL CORPS APPOINTMENTS.

A RECENT Army Order provides that medical practitioners who are required for service in an emergency shall be commissioned into the Special Reserve or Territorial Force, under the same conditions of service and the same rates of emoluments as apply to officers of those forces; and that, in the event of it being found necessary to grant temporary commissions, officers to whom such commissions are granted shall not receive more advantageous emoluments than those applicable to officers of the Special Reserve and Territorial Force.

Officers of the Special Reserve or Territorial Force who have passed through a Royal Army Medical Corps unit of the Officers Training Corps will be granted, on first appointment to the Special Reserve or the Territorial Force, seniority of six months if they have by examination obtained Certificate B (Medical), and seniority of three months if they have obtained Certificate A (Medical).

On mobilisation officers who have obtained Certificate B or Certificate A will be considered for appointments in preference to those not so qualified.

ROYAL NAVAL MEDICAL SERVICE.

The commissions of the following officers have been terminated from August 1st, 1919, the date of their being granted permanent commissions in the R.A.F.: Surg. Cmdrs. H. V. Wells, C. E. C. Stanford, A. W. Iredell, H. Cooper; Surg. Lieut.-Cmdrs. A. V. J. Richardson, W. A. S. Duck, A. E. Panter.

Surg. Capt. C. S. Woodwright to be Surgeon Rear-Admiral.

Surgeon Lieutenants to be Surgeon Lieutenant-Commanders: R. A. W. Ford, C. H. M. Gimlette, W. H. A. Sinclair-Loutit, W. J. Gerrard, R. Biddle, W. P. Vicary, A. C. Shaw, R. K. Shaw, R. A. Brown, A. C. V. Green.

Surgeon Lieutenants (Dental) to be Surgeon Lieutenant-Commanders (Dental): G. E. Wood, J. R. Palmer, W. C. Murray, E. E. Fletcher, F. Thompson, J. F. Place, D. Paterson, R. R. Adams, T. A. B. Corless, J. S. F. Horton, H. M. Meek, P. G. Richards, A. Lawrey, B. J. Geekie.

ROYAL ARMY MEDICAL CORPS.

Lieut.-Col. E. E. Ellery retires on retired pay.

Majors relinquishing the acting rank of Lieutenant-Colonel: G. H. Stevenson, T. H. Scott (Bt. Lieut.-Col.) J. M. H. Conway.

Majors retiring on retired pay: G. Baillie (on account of ill-health contracted on active service), R. N. Woodley.

Captains to be Majors: (Bt. Majors) C. Ryles, W. E. Marshall, T. J. Mitchell, W. G. Wright, A. J. T. McCreery, S. W. Kyle, D. S. Buist, A. M. Pollard, G. G. Collet, C. Clarke, (Temp. Majors) E. W. Vaughan, G. S. Parkinson, A. N. R. McNeill, A. R. Wright (and to be Brevet Lieutenant-Colonel), T. B. Nicholls, J. B. Jones, J. A. Clarke, S. McK. Saunders, (acting Major) D. H. C. MacArthur, H. Gall, C. H. O'Rourke, J. Startin, G. H. Stack, H. H. Leeson, J. W. Lane.

To be acting Majors: Temp. Capt. E. G. M. Gilchrist, D. Miller. The undermentioned relinquish the acting rank of Major: Capt. H. R. L'Estrange, A. L. Aymer, H. G. Robertson, H. C. Todd, W. McM. Chesney, F. P. Rankin; Temp. Capt. D. Gillespie, A. H. Greg.

Capt. J. F. W. Meenan, from Special Reserve, to be Captain.

Capt. D. J. H. Jones, from Special Reserve, to be Lieutenant and to be temporary Captain.

Officers relinquishing their commissions: Temp. Lieut.-Col. A. Lingard (and retains the rank of Lieutenant-Colonel), Temp. Capt. H. R. L. Joy (and is granted the rank of Major). Temporary Captains retaining the rank of Captain: S. J. W. Donald, C. L. Driscoll, W. A. Hotson, F. H. Whyte, H. Stewart, H. H. Crickitt, W. H. Booth, N. Purcell, G. L. Neil, W. A. Higgins.

SPECIAL RESERVE OF OFFICERS.

Capt. C. J. Rogerson relinquishes the acting rank of Lieutenant-Colonel.

Capt. T. C. Storey relinquishes the acting rank of Major.

The undermentioned Captains relinquish their commissions: J. J. McI. Shaw (and is granted the rank of Major), J. W. Gray, and I. L. Waddell (retain the rank of Captain).

TERRITORIAL FORCE.

Capt. J. E. Lascelles resigns his commission and retains the rank of Captain.

ROYAL AIR FORCE.

Medical Branch.—Capt. P. McDiamid is transferred to unem-ployed list. Capt. J. B. Barnett relinquishes his commission on ceasing to be employed, and is permitted to retain his rank.

Dental Branch.—Flying Officer R. H. Moore to be Flight Lieutenant.

INDIAN MEDICAL SERVICE.

Capt. A. A. C. McNeill to be Major.

Maj.-Gen. Patrick Hehir, C.B., C.M.G., C.I.E., I.M.S., has been promoted to be a Knight Commander of the Most Eminent Order of the Indian Empire for services during the operations against Afghanistan.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

Reform in the Law of Death Certification.

A JOINT deputation representing the British Medical Association and the medical Members of the House of Commons was received on Tuesday, August 3rd, by Mr. SHORTT (Secretary for Home Affairs) and Dr. ADDISON (Minister of Health) on the question of reform in the law relating to death certification and the procedure of coroners' courts. Mr. BISHOP HARMAN, who presented the case on behalf of the deputation, said the present system of death certification was valueless from the scientific point of view. He urged that death certificates should be in duplicate, one half indicating the fact of death and the other—a private document—should give the actual cause of death. Registration was carried out so loosely at the present time that numerous bodies were buried without being certified by a medical man or made the subject of a coroner's inquest. The object of the coroner's court of inquiry was really to determine the cause of death, and therefore the coroner ought to be a medical man. Mr. HARMAN suggested that he would prefer an officer similar to the Procurator Fiscal in Scotland. The Home Secretary interposed to say that that was according to French law, and in England they regarded the French law as bad. As to the suggestion that the coroner should always be a medical man, Mr. SHORTT said that if that were proposed no doubt the Government would have a deputation of lawyers urging that the coroner should always be a lawyer. Mr. HARMAN went on to argue that the fees provided for medical men who conducted post-mortem examinations and for their attendance at inquests were entirely inadequate. This point was sympathetically received by the Home Secretary. Dr. FARQUHARSON, M.P., pointed out that certain coroners, in accordance with the Act of 1914, conducted private inquiries which saved the cost of an inquest. He suggested that in such cases the coroner should be compelled before granting the right of burial to receive a written statement from a medical man giving his opinion as to whether death was due to natural causes or whether there was suspicion of violence. Dr. ADDISON said that he thought the point was a most important one, and the Home Secretary was sympathetic to a change in the law in this direction. Neither of the Ministers, however, held out any hope that legislation would be introduced on the lines suggested by the deputation.

HOUSE OF LORDS.

FRIDAY, AUGUST 6TH.

Proprietary Medicines Bill.

On the motion that the House go into Committee on the Proprietary Medicines Bill,

Lord BLEDISLOE expressed the hope that no attempt would be made to whittle down the important provisions of the measure. Never had such a tissue of fraud and falsehood been disclosed as was disclosed before the Select Committee in regard to some of these proprietary preparations. Through advertisements in the less reputable section of the newspaper press deception was practised on credulous persons of the servant girl and shop assistant class. In no civilised country in the world was less protection afforded than in the United Kingdom against the class of medicine with which this Bill dealt.

Viscount ASTOR (Parliamentary Secretary to the Ministry of Health) said one of the main objects of the Bill was to protect the health of the public. They had not attempted to deal with profiteering.

The House then went into Committee on the Bill, the Earl of DONOUGHMORE in the chair.

On Clause 1, which provides for the control of the manufacture and sale of proprietary medicines and appliances,

Lord EMMOTT moved to leave out the provision that the ingredients and composition of a proprietary medicine should be set forth on the proposed register of medicines and appliances. Such a provision, he said, might lead to the disclosure of the ingredients to a rival manufacturer. He moved to substitute instead a statutory declaration furnished to the register that the patent medicine was compounded of the ingredients mentioned in the declaration. In the opinion of the manufacturers of these medicines some members of the medical profession were "out" to destroy their trade, with the incidental effect of increasing their own earnings. He, however, was not concerned with that quarrel. His desire was to see justice done to the public. The medicines which were mainly intended for export were harmless syrups, which, like the present Coalition Government, exercised a soothing effect upon a considerable proportion of the country.

Viscount ASTOR resisted the amendment on the ground that it would strike out of the Bill one of its most important provisions. He contended that the administration of the measure would not require a large staff of officials. There was no doubt that sick persons in some cases got worse through treating themselves with proprietary medicines and neglecting the consultation of a medical man. There might be ingredients in proprietary medicines which were not poisonous, but which, if taken in excessive doses, did in fact injure the health of those who took them. He did not, however, wish to create a prejudice against patent medicines generally, or to suggest that all these proprietary remedies were injurious.

Lord DAWSON of PENN pointed out that the Bill would protect the public from combinations of drugs that might be harmful.

Lord RIDDELL urged that they were dealing with a very big business in which millions of capital were involved. The taking of patent medicines was a recreation with many people. He did not suppose that patent medicines had a monopoly of poisoning. People had been poisoned by doctors and otherwise. It was most important in the interest of the public that a careful measure should be devised, and he did not regard the present Bill as such a measure, more particularly in its provisions with respect to registration.

Viscount ASTOR said that the Ministry of Health did not wish to do anything that would harass the public, or injure the legitimate interests of the trade. The Ministry would do everything it could to ascertain what the trade had to say with a view to additional safeguards being introduced if they were found to be necessary. It was, however, right that the ingredients of these preparations should be disclosed confidentially to the Ministry.

The amendment was withdrawn.

On Clause 3, which deals with offences in connexion with the advertising of these remedies, an amendment moved by Lord EMMOTT to delete paragraph (a), which provided that a person should be guilty of an offence if he enclosed with or in the parcel or wrapper containing a proprietary medicine or surgical appliance any written matter (not being an ordinary trade catalogue) advertising the use of another proprietary medicine or surgical appliance, was agreed to.

Viscount ASTOR moved an amendment to Clause 4 (registered medicines and appliances), providing that the Registrar should not furnish any copy of extract from any formulae relating to any registered medicine to any person other than the registered owner.

The amendment was agreed to.

Lord BLEDISLOE moved an amendment to Clause 5, which deals with regulations, requiring that in the case of any synthetic drug sold as a proprietary medicine the chemical name should appear on the label and in every advertisement relating to it.

The amendment was agreed to.

On the motion of Lord BLEDISLOE, it was also agreed to increase the maximum amount of the fine for a misdemeanour under the Bill from £100 to £500, and for any other offence under its provisions from £20 to £50.

The remaining clauses of the Bill were passed without amendment, and the measure as amended was then reported to the House.

HOUSE OF COMMONS.

WEDNESDAY, AUGUST 4TH.

Cost of the Housing Shortage.

Mr. BRIANT asked the Minister of Health if he would state what was the total sum of money required to make good the shortage of houses in the United Kingdom; and how was it proposed to provide this sum.—Dr. ADDISON replied: At present prices I estimate that the capital sum required to make good the shortage of houses will amount to approximately £120,000,000 a year. I hope that the sum needed will be provided as it is required by the investment of their savings by the people of this country.

Shortage of 800,000 Houses in England and Wales.

Major ENTWISTLE asked the Minister of Health if he would state what was now the total estimated shortage of houses in the United Kingdom.—Dr. ADDISON replied: Housing in Scotland and Ireland does not come within the purview of my department, but in England and Wales the total estimated need as disclosed by surveys made by local authorities in pursuance of Section 1 of the Housing Act, 1919, amounted in gross to 800,000 houses, taking account of replacements of existing unsatisfactory houses.

Soldier's Death at Edmonton Infirmary.

Sir PHILIP PILDITCH asked the Secretary for War if he proposed to give effect to the verdict of the coroner's jury in the case of the death of Private George William Henry Elsley, at Edmonton Infirmary on July 9th, calling upon the military authorities to hold an inquiry, which verdict had been conveyed to the War Office.—Mr. CHURCHILL

replied: This case is still the subject of investigation by the military authorities, and I will let the honourable Member know the result as soon as possible.

Pensions of Dependents of Indian Officers.

Colonel YATE asked the Secretary of State for India if he could now state what decision had been arrived at on the subject of an increase in the pensions of the widows, children, and dependents of deceased officers of the Indian Army, the Indian Medical Service, and the Royal Indian Marine.—Mr. MONTAGU replied: So far as the widows, children, and other dependents of officers of the Indian Services who lost their lives in the Great War are concerned the benefits admissible have been substantially improved by the Warrant of July 2nd, 1920, the main provisions of which will be applied to the Indian Services. As regards the dependents of officers who died before the war, or whose death was not due to service in the war, I much regret that it has not yet been possible to come to a decision, as it has been necessary to take into consideration the effects of the provisions of the Pensions Increase Bill which is now before the House. I can assure my honourable and gallant friend that I will do all in my power to expedite a decision.—Colonel YATE: Does the decision on this matter rest on the passing of this Bill now before the House, or when will a decision be come to?—Mr. MONTAGU: No, it does not rest on the passage, but it does rest on the consideration of these provisions.—Colonel YATE: Can the right honourable gentlemen say when these provisions will be considered?—Mr. MONTAGU: We are considering the matter now. It is very urgent to come to an immediate decision, and I am trying to get a decision as quickly as possible.

THURSDAY, AUGUST 5TH.

Women and the Welsh Board of Health.

Major BREESE asked the Minister of Health whether, in the selection of members to serve on the Board of Health for Wales, he proposed to appoint one or more women; and, if not, would he state the reason.—Dr. ADDISON replied: I can assure the honourable and gallant Member that the question of appointing a woman member of the Welsh Board of Health has received my serious consideration, but it is probable that the number of members already appointed will be found sufficient for the work I do not consider that it would be justifiable to add to that number at the present time.

Sports Associations and the Open Spaces Bill.

Mr. JOHN DAVISON asked the Lord Privy Seal whether he was aware that sports associations throughout the country were desirous of sending a representative deputation to him to urge the necessity in the interests of the health and recreation of the people of the passage of the Open Spaces Bill; and whether he would receive the deputation at an early date in order to ascertain from them the volume of opinion in favour of the Bill and of its early passage into law.—Mr. BONAR LAW replied: I doubt whether any useful purpose would be served by receiving a deputation on this subject, but I shall discuss it with my right honourable friend, the Minister of Health, whose department is concerned in it, and let the honourable Member know whether it is possible for my right honourable friend or myself to receive the deputation.

MONDAY, AUGUST 9TH.

Conditions of Hospital Probationers.

Viscountess ASTOR asked the Minister of Health whether his attention had been drawn to the conditions under which nursing probationers in many London hospitals at present worked, especially with regard to housing accommodation and hours and conditions of duty; and whether he would consider recommending reforms in these connexions to all hospitals in receipt of State grants for the benefit both of probationers and of the nursing profession generally.—Dr. ADDISON replied: I am fully aware of the unsatisfactory conditions under which many probationer nurses are at present employed, and any steps which the General Nursing Council may propose to remedy this state of affairs will have my sympathetic consideration. State grants, however, are only paid in respect of the treatment of certain specified diseases, and I do not think it would be practicable to attach to them conditions such as the honourable Member suggests.

Facilities for Visiting Service Men in Hospitals.

Mr. W. H. SMITH asked the Minister of Transport whether he was aware that a large number of soldiers still in hospital at a distance from their homes were without the necessary means to enable them on occasion to visit their families, and that the members of their families for the same reason are unable to visit the hospitals; and whether he would consider the possibility of these men or their families being granted travelling facilities at cheap rates.—Sir ERIC GEDDES replied: I have every sympathy with the case of soldiers still in hospital and their desire to see their families. I am not, however, in favour of piecemeal concessions. The treatment of disabled soldiers and sailors must

be regarded as a whole, and I do not think any portion of the cost should in an indirect way be borne by the Railway Agreements Vote. It is a matter for the War Office, Minister of Labour, or Minister of Pensions, not for the Minister of Transport.

TUESDAY, AUGUST 10TH.

London University Site.

Mr. LORDEN asked the Chancellor of the Exchequer whether, as the Senate of London University had not accepted the offer of the Government of a site in Bloomsbury, he would say if, in the event of the Senate of London University approving Kenwood, Highgate, as a suitable site for the University, the Government would provide similar financial aid equal to the cost of the Bloomsbury site.—Mr. CHAMBERLAIN replied: No, Sir. The offer of the Bloomsbury site afforded the Senate an opportunity of establishing the University close to the British Museum with its unrivalled facilities for students and of collecting in one group the central buildings of the University and its principal constituent colleges. The purpose of the offer was to enable the University to rise to the high level of its opportunities and duties as the Metropolitan University of the Empire. This purpose would not be secured by the selection of another site not affording the same facilities, and H.M. Government would not feel justified in calling upon the general taxpayer for such an extraordinary contribution upon any other grounds.

Prison Medical Officers.

Mr. HANCOCK asked the Home Secretary whether he would consider the desirability of the transfer of the prison medical service to the Ministry of Health and of prison education to the Board of Education.—Mr. SHORTT said in reply: The arrangements for maintaining the health of prisoners and providing means of education are intimately bound up with general questions of prison administration, and it is most undesirable that the responsibility for this should be divided between three separate departments of Government.

Assaults upon Children.

Viscountess ASTOR asked the Home Secretary whether he was aware of the increase in the number of cases of criminal or indecent assaults on children; and whether, in view of the seriousness of the offence, he would consider the advisability of taking steps so that the sentences which could be imposed under summary jurisdiction should be increased, or that all such cases should be tried before a superior court.—Mr. SHORTT replied: No evidence of any general increase in the number of assaults on children has been brought to my notice. If the honourable Member will let me have any evidence on this point that she may have in her possession I will consider the matter further.

Medical Officers in the Colonial Service.

Lieutenant-Colonel FREMANTLE asked the Under Secretary for the Colonies whether there was at present a shortage of medical officers in the Colonial Service; whether this was an obstacle to the health and development of the colonies, and was largely due to the comparative unattractiveness of the Service; whether he had now received and would publish the report of the Committee which had recently investigated the subject; and would he state in what way and how soon he proposed to introduce the required and obvious remedies.—Colonel AMERY replied: I am aware that the shortage to which my honourable friend refers does exist, and that it is by no means confined to the Colonial Service. Improvements in the pay of medical officers have already been carried out in the majority of colonies and protectorates. The Secretary of State has recently received the report of the Committee referred to. It requires careful consideration, and I am not yet in a position to say what action will be taken upon it or whether it will be published.

Director-General of the Army Medical Service.

Lieutenant-Colonel FREMANTLE asked the Secretary for War whether he had considered the advisability of guarding against the breakdown of medical arrangements and of securing greater physical efficiency in military operations by placing the Director-General of the Army Medical Service on the Army Council with responsibility and power to secure the full consideration of health matters and the execution of all medical arrangements.—Mr. CHURCHILL said in reply: Whenever matters affecting medical organisation or administration are under consideration the Director-General of the Army Medical Service is called upon to give the Army Council the benefit of his advice. I do not think, therefore, that there is any advantage to be gained by making him a Member of Council.

Lieutenant-Colonel FREMANTLE: Is it not realised that the Director-General has to deal with a very large number of medical problems that arise in connexion with strategic questions on which he alone can give an opinion?—Mr. CHURCHILL: That point has been very carefully considered. We have the benefit of the advice of the Director-General of the Medical Services at any time, and of a great many other

very highly skilled technical officers, but that is not a reason for adding these officers to the Army Council.—Lieutenant-Colonel FREMANTLE: How does the right honourable gentleman propose to get over the difficulties of hospital arrangement in a campaign coming under the head of three departments with three different members of the Army Council? There must surely be divided counsel.—Mr. CHURCHILL: I do not think there is any great difficulty in practice arising from that.

Medical News.

ROYAL COLLEGES OF PHYSICIANS OF LONDON AND SURGEONS OF ENGLAND.—At the Final Examination, held from July 6th to 27th, the following candidates were approved in the undermentioned subjects:—

Medicine.—Doris Elizabeth Alcock, Royal Free; O. A. Baker, Univ. Coll.; Marjorie Muriel Sibley Bartlett, Royal Free and St. George's; Ivy Constance Beach, St. Mary's; A. H. Bean and A. Bearblock, Univ. Coll.; C. H. Bracewell, St. Bart's; Hylda Catherine Briscoe, Royal Free and St. Mary's; C. G. Bryan, London; A. Y. Cantin, London and Paris; G. H. A. P. Clavier, London; Beatrice Lakeman Collins, King's Coll. and St. George's; Elsie Eleanor Cowperthwaite, Royal Free and St. Mary's; F. P. de Caux, St. Bart's; A. H. G. Down, Univ. Coll.; T. A. Eccles, St. Bart's; R. W. Fairfax, Charing Cross; M. R. Flynn, Sydney; O. P. Gallegos, Charing Cross; R. M. Galloway, Edinburgh; W. R. W. Haight, Toronto Univ.; C. K. J. Hamilton, St. Thomas's and Oxford; H. W. Hammond, St. Bart's; I. Harris, Liverpool; Joan Margaret Redford Harris and Eleanor Harse, Royal Free; E. Hiam, Middlesex; J. T. S. Hoey, Oxford and St. Thomas's; S. H. G. Humfrey, Cambridge and St. Thomas's; M. F. Ismail, Guy's; R. O. Jones, Liverpool; A. E. Kassem, Guy's; Margaret Hypatia Kingsford, Royal Free; F. C. Lewis, Liverpool; E. T. Lloyd, Guy's; Kathleen Maria Boyce McArthur, St. Mary's; R. A. McCabe, Middlesex; Elisabeth Esther McCulloch, Liverpool; H. A. C. Main, St. Mary's; E. J. Newton, Royal Free; T. D. Overend, Univ. Coll.; Alice Owen, Dorothy Pantin, and Winifred Peacey, Royal Free; Arulmani Pichaimuthu, Charing Cross; Winifred Catherine Piggott and Norah Katharine Priestley, Royal Free; J. S. Robinson, Manchester; W. G. Rose, St. Mary's; Frederick M. Rossiter, Pennsylvania and Univ. Coll.; A. R. Roushdy, Charing Cross; Maud Sanderson, St. Mary's; Constance Snowden, Manchester; G. W. Theobald, Cambridge and St. Bart's; H. E. Thomas, Univ. Coll.; N. G. Thomas, St. Bart's; C. J. A. Tion-A-Man, Middlesex; Mary Isabel Turner, Manchester; Madeline Hilda Jane Umpleby, St. George's; Constance Muriel Willis, St. Mary's; E. F. Wilson, Guy's; and Beryl Wischam, London.

Midwifery.—R. B. Agaskar, Middlesex; C. H. Andrewes, St. Bart's; L. H. Appleby, Queen's Univ.; T. J. D. Atteridge, St. Bart's; E. T. Bailey, Middlesex; W. E. Barnes, Univ. Coll.; S. H. Barnett, Cambridge and St. Thomas's; H. E. Beasley, Univ. Coll.; E. F. H. Bell, Durham; B. Bharatani, Madras and King's Coll.; H. J. Bhatia, Bombay; W. Breakell, Cambridge and Univ. Coll.; C. G. Bryan, London; F. C. W. Capps, St. Bart's; D. S. Chamberlain, King's Coll.; S. B. Chambers, Charing Cross; Dorothy Alice Denman Cropper, Cambridge and Edinburgh; P. T. Davidson, Middlesex; H. K. Denham, St. Bart's; A. G. Duncan, London; E. W. Evans, Birmingham; E. C. Faraker, Guy's; A. J. Fenn, King's Coll.; J. Franks, London; H. Freeman, Westminster; E. Gallop, St. Bart's; R. M. Galloway, Edinburgh; M. Garden and Janet Katherine Gatty, Univ. Coll.; J. B. Gregor, Guy's; B. J. Hallows, St. Bart's; C. B. Hawthorne, Cambridge and Birmingham; W. E. Hayes, Oxford and St. Bart's; S. Hazeldine, Univ. Coll.; J. W. Hirst, Cambridge and King's Coll.; J. W. Hulme, Middlesex; B. L. Jeaffreson, St. Bart's; W. D. Jenkins, Middlesex; L. M. Jennings, St. Bart's; T. T. Jones, Manchester; E. J. L. Jones-Evans, St. Thomas's; H. C. V. Joy and M. Korn, London; F. G. Latham, Liverpool; H. D. Lawson, London; Bessie Levin, Univ. Coll.; E. O. Lewis, Cambridge and Univ. Coll.; I. Lewis, Univ. Coll.; D. McClean, St. Thomas's; Elizabeth Kathleen Mackay, Oxford and Charing Cross; C. C. Mackinnon, Middlesex; O. T. MacLaren, Guy's; Elizabeth Matthai, Royal Free; G. G. Michell, Univ. Coll.; W. P. Newman, St. Thomas's; E. J. Newton, Royal Free; S. Orchard, Cambridge and St. Bart's; Winifred Peacey, Royal Free; T. L. Pires, Charing Cross; J. J. Redelinghuys, Univ. Coll.; B. T. Richards, Birmingham; P. L. Richardson, Guy's; J. S. Robinson, Manchester; Mary Frances Roope, Charing Cross; I. Rosenberg, Guy's; F. M. Rossiter, Pennsylvania and Univ. Coll.; Maud Sanderson, St. Mary's; E. T. Saravanamuttu, Madras and Edinburgh; C. I. Schiff, London; Florence Gertrude Sherry, Manchester; M. Sidky, Guy's; G. S. Sinnatamby, Ceylon; Elfrida Elizabeth Ada Spencer, Charing Cross; H. Spiby, Cambridge and Univ. Coll.; P. Steinberg, London; R. N. L. Symes, St. Thomas's; H. B. Taylor, St. Mary's; E. W. C. Thomas, St. Bart's; D. R. Thompson and J. P. Traylen, London; Mary Isabel Turner, Middlesex; Mary Gwendolen Vaughan, King's Coll.; J. G. Walker, Charing Cross; R. A. Walker, St. Thomas's; W. J. G. Walker, Univ. Coll.; L. K. Watson, Guy's; R. Weaver, Belfast; Agnes Edie Westwood, St. Mary's; Valentine Wilkinson, Cambridge and Univ. Coll.; W. H. Williams, Charing Cross; Constance Muriel Willis, St. Mary's; and W. C. S. Wood, King's Coll.

Surgery.—F. F. Abdullah, St. Mary's; G. W. Almeyda, London; Joan Katharine Somerville Cave, Royal Free; R. D. Cowan, Univ. Coll.; E. J. Crisp, Guy's; I. G. de Silva, Madras; F. H. Edwards, Liverpool; Madeline Giles, St. Mary's; W. Götho,

Middlesex; G. E. Hayward, Manchester; H. J. H. Hendley, Cambridge and St. Bart.'s; R. O. Jones, Liverpool; M. H. K. Kane and I. Lewis, Univ. Coll.; A. Maude, Manchester; E. O. Morrison, Cambridge and St. Mary's; S. Orchard, Cambridge and St. Bart.'s; Dorothy Pantin, Royal Free; A. S. Pearson, Birmingham; Winifred Catherine Piggott, Royal Free; A. D. Porter, King's Coll.; J. L. Potts, Cambridge and St. Bart.'s; A. M. Ramzy, Cairo and Charing Cross; W. Remington, Guy's; W. G. Rose, St. Mary's; G. R. A. de M. Rudolf, King's Coll.; R. G. V. Shaw, Sydney; F. V. Squires, Cambridge and St. Thomas's; J. A. Stephens, Leeds; A. H. Talaat, Middlesex; K. H. Tallerman, Cambridge and St. Thomas's; B. W. Thompson, Cambridge and St. Bart.'s; F. I. G. Tweedie and A. R. Walker, Cambridge and St. Thomas's; K. T. K. Wallington, Univ. Coll.; and H. N. Witham, St. Thomas's.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.—At the last meeting of the Comitia, in addition to the business reported last week, the following recommendations were received from the Committee of Management:—

(1) That the University of Groningen be added to the list of universities recognised by the Examining Board in England.

(2) That candidates who have completed the courses of instruction and passed the examination in anatomy and physiology for the science degree of the University of Cape Town, be exempted from passing the second examination of the Examining Board in England.

(3) That the courses of instruction in anatomy and physiology at the South African School of Mines and Technology, Johannesburg, a College affiliated to the University of Cape Town, be accepted as fulfilling the requirements of the Regulations of the Examining Board in England in regard to the study of these subjects.

(4) That the requirement that a candidate should have attained the age of 23 years and 24 years before entrance to Examination in Parts I. and II. respectively, for the diploma in public health, be omitted from the Regulations for that diploma.

The Committee recommend that the following schools be added to the list of institutions recognised by the Board for Instruction in Chemistry and Physics—namely, County Borough of Blackpool Secondary School, Caterham School, Bishop's Stortford College, and the Victoria Institute, Worcester; and that the Coventry and Warwickshire Hospital be added to the list of recognised hospitals. The Committee recommend that the following be added to the list of institutions whose graduates in medicine are admissible to the final examination of the Examining Board in England under the conditions of Paragraph IV., Sections III. and IV. of the Regulations—viz: The State University of Ohio, the University of North Dakota, the University of Kansas City, the University of Hong Kong, the University of Virginia.

Sir Charles Ballance, on the recommendation of the Committee, was appointed visitor to the examinations of the Egyptian School of Medicine for the next period of examination.

THE NATIONAL ASSOCIATION for the Prevention of Consumption and Other Forms of Tuberculosis is holding its eighth annual conference in St. George's Hall, Liverpool, from Thursday to Saturday, Oct. 7th-9th. Special attention will be devoted to preventive measures.

UNIVERSITY OF LONDON: THE DIPLOMA IN PSYCHOLOGICAL MEDICINE.—The University of London has instituted recently a diploma in Psychological Medicine, the regulations for the obtaining of which have now been published. The examination is held twice in each year and is divided into two parts, Part A being held in March and October and Part B in April and November, and only for candidates who have passed Part A. Part A deals with the anatomy, histology, and physiology of the nervous system, one paper being also set in psychology. For Part B the candidates are examined in neurology and psychological medicine, the papers containing alternative sections enabling the candidate to specialise. Before being admitted to Part B the candidate must hold for six months a resident appointment at an institution for mental diseases, or attend for a year the practice therein, or pursue similar studies, with the approval of the University, in some other direction. Further information as to fees and syllabus will be given, on application, by the University Extension Registrar, Mr. John Lea, M.A., University of London, South Kensington.

LITERARY INTELLIGENCE.—Messrs. J. and A. Churchill announce for publication the following new books and new editions:—"The Anatomy of the Human Skeleton," second edition, by J. E. S. Frazer, F.R.C.S.; "Massage, its Principles and Practice," second edition, by J. B. Mennell, M.D.; "A Manual on Dental Metallurgy," fourth edition, by E. A. Smith; "A Handbook of Physics and Chemistry," fifth edition, by H. E. Corbin and A. M. Stewart; "A Text-book of Materia Medica," third edition, by Professor H. G. Greenish; "Catalysis and its Industrial Application," second edition, by E. Jobling, A.R.C.Sc.; and "A Synopsis of Hygiene," especially intended for those studying for a diploma in public health, by W. W. Jameson, M.D., and F. T. Marchant, M.R. San. Inst.—Messrs. Williams and Wilkins Company, London and Baltimore, announce the forthcoming appearance of "The Determination of Hydrogen

Ions" by W. Mansfield Clark, Ph.D., containing numerous illustrations, an indicator chart in colours, and a bibliography of 1100 references. The price in England will be \$5.50.

FEES FOR EXAMINATION FOR LIFE INSURANCE.—There has been discontent for a considerable time in the medical profession of Ireland over the inadequacy of the guinea fee as remuneration for an examination for life insurance. Some months ago several medical examiners declined to report for one guinea and demanded a fee of two guineas. In most cases the increased fee was readily paid. The Council of the Irish Medical Association then took the matter up and decided on a standard fee of two guineas, with the concession that in the case of small insurances (for policies of less than £500) one guinea would be accepted. More recently the medical examiners resident in Dublin held a meeting under the presidency of the President of the Royal College of Physicians, and decided to adopt the standard laid down by the Council of the Irish Medical Association. Notice has been given to the various insurance offices in Dublin of the decision of the meeting, and it is expected that the larger fee will be readily paid.

LONDON SCHOOL OF MEDICINE FOR WOMEN.—A post-graduate course of instruction in the treatment of venereal diseases will be held during the fortnight beginning Monday, Sept. 13th, for qualified medical women. The course is in connexion with the London (Royal Free Hospital) School of Medicine for Women and the Royal Free Hospital, the Elizabeth Garrett Anderson and the London Lock Hospitals. Application for admission to the course should be made to the Secretary, Medical School, 8, Hunter-street, London, W.C.1., from whom particulars can be obtained.

The following scholarships have been awarded from October next:—

St. Dunstan's Medical Exhibition: Miss E. Masterman (Hamilton House School, Tunbridge Wells).
Isabel Thorne Scholarship: Miss E. Adams Clarke (Sydenham High School).
Mabel Sharman Crawford Scholarship: Miss F. I. Moore.
Sir Owen Roberts Memorial Scholarship: Miss M. Weststead.
Lewis Memorial Scholarship: Miss E. H. R. Newbould.

Appointments.

EVANS, D. E., M.B. Lond., has been appointed an additional Medical Referee under the Workmen's Compensation Act, 1906, for County Court Circuit No. 31, attached more particularly to the Neath and Aberavon County Courts.
GOODWIN, A., O.B.E., M.D., B.S. Lond., F.R.C.S. Edin., Obstetric Tutor to the Westminster Hospital.
LEWIS, E. C., M.B., M.S., F.R.C.S., Assistant Surgeon to the Royal Free Hospital.
SALISBURY-SHARPE, W., M.D., F.R.C.S.I., Assistant Surgeon to the Central London Throat and Ear Hospital.
SINCLAIR, N. F., F.R.C.S. Eng. & Edin., Assistant Surgeon to the West London Hospital.

Vacancies.

For further information refer to the advertisement columns.

Barnes, Beckett Hospital and Dispensary.—Sen. H.S. £250.
Battersea General Hospital (Incorporated), Battersea Park, S.W.—Third Res. M.O. £200.
Belfast County Borough.—Bacteriologist and Pathologist. £700.
Bellahouston Hospital, Glasgow, Ministry of Pensions.—Med. Electrician. £650. Pathologist. £300. Two Anesth.'s. £350 or £450. Three P.'s or S.'s. £450.
Bengal, University of Dacca.—Chair of Physical Education. Rs. 9000 to Rs. 12,000.
Berks and Bucks Joint Sanatorium, Peppard Common, Oxon.—Asst. Res. M.O. £350.
Birmingham Children's Hospital.—Jun. Vis. Anesth. £50. Res. M.O. £150.
Birmingham City Hospital for Infectious Diseases.—Asst. Res. M.O. £350.
Birmingham General Hospital.—Res. M.O. £155. Res. Anesth. £100. H.S. £125.
Birmingham University.—Lect. in Physiology. £250. Demonstrator in Pathology. £350.
Blackburn and East Lancashire Royal Infirmary.—Jun. H.S. £250.
Bristol Eye Hospital.—H.S. £150.
Canterbury, Chatham Mental Hospital.—Asst. M.O. £350.
Colonial Service.—M.O.'s for West African Medical Staff, Government Service in Malaya, East African Protectorates, West Indies (including British Guiana), Fiji, and the Western Pacific, &c.
Coventry Education Committee.—Two Sch. Dentists. £500.
Derby Borough Mental Hospital.—Asst. M.O. £350.
Dorset County Council.—Asst. County M.O.'s. £500.
Dreadnought Hospital, Greenwich.—H.S. and H.P. £100.
Dumfries, Crichton Royal.—Asst. P. £350.
East Ham Education Committee.—Sch. Aurist.
Essex Education Committee.—Sch. Med. Inspec. £500.

Glasgow, Victoria Infirmary.—Jun. Asst. P. £100. Med. Tutor. £300.
 Great Yarmouth General Hospital.—H.S. £250.
 Hampstead General and North-West London Hospital, N.W.—
 Clin. Asst., Ear, Nose, and Throat.
 Hertford County Hospital.—H.S. £200.
 Hospital for Consumption and Diseases of the Chest, Brompton.—
 H.P.
 Huddersfield Royal Infirmary.—Asst. H.S. £150.
 Ingham Infirmary and South Shields and Westoe Dispensary.—
 Jun. H.S. £175.
 Isle of Wight, Royal National Hospital for Consumption, Ventnor.—
 Locum Asst. Res. M.O. 6 guineas per week.
 Lancashire County Council, Rufford Sanatorium and Training
 Centre.—Med. Supt. £800.
 Leasowe Hospital for Children, Cheshire.—Jun. Res. M.O. £200.
 Leeds University, School of Medicine.—Lect. in Exper. Phys. £500.
 Lincoln County Hospital.—Jun. H.S. £150.
 Liverpool, David Lewis Northern Hospital.—Two H.P.'s and Three
 H.S.'s. £120.
 Liverpool, Royal Southern Hospital.—Two H.P.'s and Three H.S.'s.
 £100.
 Liverpool School of Tropical Medicine.—Three Medical Men for
 Clinical and Research Work in Tropical Medicine.
 London County Council Mental Hospital Service.—Asst. M.O.'s.
 London Lock Hospital, Soho, W.—H.S. £200.
 London Temperance Hospital, Hampstead-road, N.W.—Cas. O.
 £200. Radiographer. £105. H.P. £120.
 London University.—William Julius Mickle Fellowship. £200.
 M.A.B. Tuberculosis Service.—Asst. M.O.'s at Margate, £515; at
 Brentwood, £579.
 Maidstone, Kent County Mental Hospital.—Jun. Asst. M.O. £300.
 Manchester, Ancoats Hospital.—H.S. £150.
 Manchester, Barnes Convalescent Hospital, Cheadle.—Res. M.O. £300.
 Manchester Children's Hospital, Pendlebury, near Manchester.—
 Two Res. M.O.'s. £150.
 Manchester Royal Eye Hospital.—Jun. H.S. £120.
 Margate, Royal Sea Bathing Hospital.—Res. S. £200.
 Metropolitan Borough of Wandsworth.—Asst. Tuberc. O. £818.
 Middlesbrough, North Ormesby Hospital.—Asst. H.S. £175.
 Natal, Corporation of Durban.—M.O. for Mat. and Child Welf. £700.
 Neath (Glamorganshire), Beckett's Park (near Leeds), and Ashurst
 (Oxford), Ministry of Pensions Hospitals.—Pathologists. £600.
 Newcastle-upon-Tyne, Royal Victoria Infirmary.—Temp. Hon. S.
 Also Refractionist. £200.
 Newcastle-upon-Tyne, University of Durham College of Medicine.—
 Sen. and Jun. Demonstrators of Anatomy. £450 and £350
 respectively.
 Orkney, Parish of Rousay and Egilshay.—Res. M.O. £300.
 Portsmouth Education Committee.—Asst. School M.O. £500.
 Queen Mary's Hospital, Stratford, E.—H.P.
 Salford Union Infirmary.—Res. Asst. M.O. £350.
 Scarborough Education Committee.—Sch. Dent. S. £250.
 Sheffield Royal Infirmary.—H.P. £150.
 Staffordshire Education Committee.—Twelve Med. Practs. £600.
 Stafford, Staffordshire General Infirmary.—H.S. £250.
 Stockport General Infirmary.—Jun. Res. S. £200.
 Surrey County Council.—Tuberc. M.O. £770.
 Taunton and Somerset Hospital.—Sen. and Jun. H.S.'s. £200 and
 £150.
 Tottenham Education Committee.—Asst. Sch. M.O. £650.
 Windsor, King Edward VII. Hospital.—H.S. £200.
 Wolverhampton and Staffordshire General Hospital.—H.S. £200.
 Woodilee Mental Hospital, Lenzie, near Glasgow.—Asst. M.O. £350.
 The Chief Inspector of Factories, Home Office, S.W., gives notice
 of a vacancy for a Certifying Surgeon under the Factory and
 Workshop Acts at Nottingham, N.

Notes, Short Comments, and Answers to Correspondents.

A SKETCH OF SEVENTY YEARS.¹

By T. PRIDGIN TEALE, M.A. OXON., F.R.S.

THINKING over my subject, I am almost "snowed under" by the number of questions that arise before me deserving serious notice. I can therefore only select those which, on looking back upon this momentous period, seem to demand attention mainly as enforcing principles, passing by with severe abstention many events and important points which tempt to digression.

Let me begin by being egotistical, and by referring to the earlier years of the Leeds School of Medicine. My medical education began in the summer of 1849, when on leaving school (Winchester) I became a pupil of the surgical practice of the Leeds Infirmary. Of this I was a regular attendant during the vacations of the three years I passed as an Oxford undergraduate at Brasenose. During these vacations I accompanied my father in his ward visits on all operations by him and his colleagues ("Sam" Smith and William Hey) and in all emergency night calls, which were numerous owing to the frequent accidents in the construction of the Arthington Tunnel. On leaving Oxford in the summer of 1852 I became a pupil of the Medical Department of King's College, London, where Fergusson and Bowman were on the surgical staff; Todd, Budd, and George Johnson were on the medical staff; Partridge and Beale were on the lecturing staff.

What was my position on commencing lectures on anatomy and physiology and on work in the dissecting-room? I entered upon these studies, having witnessed, in the companionship of my father, nearly every surgical operation then in use, and I had attended and noted every post-mortem for which my vacations at Leeds afforded the opportunity. Think what this meant in giving reality and intense human interest to a beginner in the medical curriculum. I make a point of this in order to emphasise what I feel about the training of a doctor.

The Evolution of the Leeds School of Medicine.

With these preliminary remarks let me tell of the evolution of the Leeds School of Medicine, making use of a passage from the address I gave to this society in 1903. The Leeds School of Medicine practically began its career as a complete school in October, 1831, in rooms in the old dispensary at the top of Templar-street, and my father gave the opening lecture. At the end of three years the Council purchased a "very commodious building"—in fact, a good double dwelling-house—at the corner of East Parade, hard by the infirmary. In this house a front and back sitting-room were thrown into one to make a museum, and a first-floor room was converted into a theatre for about 25 students. A small narrow dressing-room was made into a place for injecting "subjects" which were brought up from below through a trap door. Skylights were put into the attics to convert them into a dissecting-room.

On the benches during the opening years there sat as students Sir Spencer Wells, Dr. Chadwick, senr., Mr. Samuel Hey, and Sir William Priestley. Inadequate as such a building would seem to us now, it was at the time not inferior to the buildings of the other provincial schools, and, aided by the teaching at the infirmary, it raised the Leeds School to a reputation not the least among the medical schools of England.

The next stage occurred in this way. As soon as a site in Great George-street was selected for the new infirmary some of the staff felt that the school must follow the infirmary, and not be left at the distance of one-third of a mile. A committee, consisting of Dr. Heaton, Mr. Wheelhouse, and myself, was appointed and the site in Park-street was purchased. Having bought the site we set to work to plan for ourselves so as to make the best possible use of the ground. We then selected an architect and put our provisional plans into his hands; he, of course, absorbed our ideas and improved upon them.

Such was the new school in Park-street—now the abode of the Thoresby Society—and it was, I believe, at that time the only school in the provinces built for the special purpose, and was far in advance of the provincial schools then in existence. This was in 1864, the year of the laying of the foundation stone of the new infirmary. The opening address was given on October 2nd, 1865, by Sir James Paget, and the following passage may well be quoted therefrom.

¹ An address to the University of Leeds Medical Society, Dec. 5th, 1919.

Births, Marriages, and Deaths.

BIRTHS.

BOYLE.—On August 9th, the wife of Dr. Boyle, Disley, Cheshire, of a daughter.
 MCCREA.—On July 31st, the wife of H. Moreland McCrea, M.D., Devonshire-place, W., of a daughter.
 MARTYN.—On July 30th, at Zeitone, Cairo, the wife of Captain A. F. C. Martyn, R.A.M.C., of a son.
 WATSON.—On August 9th, to Dr. and Mrs. G. W. Watson, of Park-square, Leeds—a son.

MARRIAGES.

JEX-BLAKE-HERBERT.—On Thursday, August 5th, in the Parish Church at Wilton, by the Bishop of Salisbury, assisted by the Rev. Guy Campbell, Arthur John Jex-Blake, M.D. Oxon., F.R.C.P., of 13, Ennismore Gardens, London, to Muriel Katharine Herbert, younger daughter of the late Earl of Pembroke, of Wilton House, Salisbury.
 REVELL-ANDREW.—On August 4th, at Lawhitton, Launceston, Rowan William Revell, M.B., B.S. Lond., D.P.H., to Edith Mary Andrew, daughter of the late M. Andrew.
 SUTHERLAND-FITZPATRICK.—On August 4th, at St. Joseph's Retreat, Highgate-hill, N., Halliday Gibson Sutherland, M.D., to Muriel Fitzpatrick, daughter of the late John Frederick Fitzpatrick and Mrs. Fitzpatrick, of Cromwell-avenue, Highgate-hill, N.
 WATTS-DUNHAM.—On August 7th, at St. Stephen's Tonbridge, Harry John Manning Watts, M.R.C.S., L.R.C.P., to Winifred Mary, second daughter of Henry Symes Dunham, of Bankside, Tonbridge.

DEATHS.

EWART.—On August 1st, very suddenly, at his residence, Eastbourne, John Henry Ewart, M.R.C.S., L.R.C.P., aged 73 years.
 RHODES.—On August 5th, at Brechin-place, S.W., J. Herbert Rhodes, M.B., M.R.C.P., aged 45 years.
 N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

"This only I will say, that from the beginning to the end of your career, and day by day, you must study diseases and their treatment in actual practice. There is nothing of which the observation of the careers of students has made me more sure than of this. If I except the few—the unhappily too few—who, after taking high degrees in the universities, have studied medicine, I should say that as a constant rule the best students, and they who have proved themselves the best not only in the schools but in after life, have been those who, in the beginning of their studies and for the most part before attending lectures, have been pupils in provincial hospitals, or with active and intelligent general practitioners, who have enabled them to see practice every day and helped them to study it.

"I am aware that this opinion—that the study of actual practice should extend through the whole period of medical education—is not held by some who have carefully thought upon the subject. They would not have this practical study, as I would—first, last, and in the midst of all. I have, therefore, again and again considered the point; but the fact always remains to me convincing, and not strange, that the best students are those who have from first to last, and always, combined the study of actual practice with that of the principles and foundations of our profession; or who, if they have begun with one of these, have begun with practice, and then studied the principles together with it."

As time went on the growth of the school and of the Yorkshire College led to the union of the two bodies in the University of Leeds. The work of the medical department was carried on for a time in the school in Park-street. It soon, however, became evident that even our "new school" was inadequate to meet the rapidly increasing demands of medical education, especially as it has to be carried on by a University College. The result, you all know, is the present School of Medicine.

Personnel of the School of Medicine.

Having dealt with the buildings we may turn to the personnel of those who had to use them as teachers or pupils. Looking back to the early days, the days preceding the removal of the school of 1834 to the new building in Park-street, 1832-65, and of the infirmary to its enlarged site in Great George-street, 1869, it must be borne in mind how the commencement of the School of Medicine was made by a certain number of medical men who had pupils or apprentices for whom they wished to provide teaching in the earlier subjects of study—anatomy, physiology, chemistry. The result of this was that they themselves, in the midst of active work, most of them busily engaged in family practice, including the surgeons to the infirmary, undertook the various lectureships, and so provided the teaching. It followed, therefore, as a result that all, or nearly all, the students were resident in Leeds, and most of them lived in the houses of medical practitioners. A further consequence was that it was possible for Mr. Sam Smith, surgeon to the infirmary, lecturer on midwifery, to deliver his course of lectures at 7 o'clock in the morning during the summer session.

The early work spread to the infirmary and enabled Mr. Wheelhouse and myself to pay our bi-weekly clinical visits to the wards at 8 o'clock in the morning, and allowed me to make that same hour the commencement of my operations at the infirmary and in private. As a further instance of the energy of the makers of the school at that period I may relate that in preparation for the meeting of the British Association in 1858 (not the B.M.A.), in order to put the museum into presentable order for the visits of scientific men, several of us—Nicholson Price, Scattergood, Wheelhouse, and myself—met twice a week from 7 to 9, revising the museum, looking over the specimens, and where necessary remounting the wet preparations. The 8 A.M. ward visits were continued by Mr. Wheelhouse and myself until our retirement as consulting surgeons in 1884.

A Quotation from an Address in 1903.

I will now quote from my address to you in 1903.

"There is one question on which I feel strongly and about which I venture to say a few words rather in the way of caution than of actual guidance. We have recently been told by a leading professor of physiology, whose opinion cannot but carry weight with us all, 'that surgery and medicine cannot be studied or understood without a previous knowledge of anatomy and physiology, and that some of his fellow-students early discovered that the time spent in the wards during these first years was wasted, and who soon discontinued the attendance until the subjects which were necessary for obtaining any benefit from it were finished with.' Perhaps they were right in the circumstances under which such attendance took place. Yet there is another side to this question, and I have always leaned to the other side, and have regretted the divorce of the early years of anatomy and physiology from any association with the human being and illness, for which all this scientific study is a preparation."

Here let me speak of the system I carried out in my ward teaching, which ended when in 1884 I became consulting surgeon at the end of my 20 years as full surgeon—35 years ago. It fell to me as junior on the surgical staff to enter names of students for attendance on the surgical practice of the infirmary. In accordance with my strong views, I encouraged the new men to commence attendance on the surgical practice of the hospital as soon as they entered for anatomy and physiology. The students attending the surgical

side were divided into four classes, one class being assigned to each of the four surgeons for attendance on the ward visits of that surgeon for three months. At the end of this time they passed on to one of the others. In making out the lists I used to assign the first year's men to my list. On meeting this class, including the newcomers, at the opening of the session, I used to say to them: "Some people hold the view and will tell you that to go round the wards and see patients when you have not learned your anatomy and physiology is waste of time. My answer would be:—

'If you have used your time aright, listening intelligently to every question put by the surgeon to patient, to dresser, to nurse, or to house surgeon, just as if they were addressed to yourself, making a mental note of what passes; if you have used the splendid opportunity vouchsafed to you as a hospital pupil, and can at the end of this first three months judge by the look whether a patient is "better or worse," you will have made a good start in clinical study, and will have acquired a habit which will stand you in good stead in your future career.'

Anæsthetics.

Now a word about anæsthetics. We will begin with laughing-gas—nitrous oxide. This was at first used as a chemical—and comical—toy. Mr. Wheelhouse used to tell of its amusing effects when he and his fellow-students at the Medical School tried it upon themselves and each other.

Next came ether from the United States, introduced by a dentist named Morton. I remember, somewhere in the very early "fifties," going with my father to see the administration of ether, by means of a cumbersome machine at the infirmary, as an anæsthetic for an operation. I have no recollection either of the apparatus used or of any operation.

About this time chloroform was discovered as an anæsthetic by Sir James Simpson and rapidly made its way to general use, though accepted with much apprehension. As time went on and the use of chloroform became general the frequency of deaths, and especially when it was used for slight operations—extraction of teeth, reduction of dislocations, and examinations otherwise painful—was creating serious alarm.

Then came an Epoch in Anæsthetics. At the International Ophthalmic Congress in London in July, 1876, Dr. Joy Jeffries, of Philadelphia, made a most urgent appeal to British surgeons to substitute for chloroform ether, which American surgeons and dentists had found to be almost free from danger—at any rate much less dangerous than chloroform. He gave ether on the open towel in large quantities. Here in Leeds we at once promptly responded. We began in the American way—first with the towel, then with the grid (brought to us from America by the infirmary chaplain, now Canon Spencer Gough, of Barningham)—struggling with difficulties, as a duty imposed upon us until at last relief came from Ormsby and Clover in their invaluable "inhalers," and ether asserted its superiority, a superiority which is now being recognised all over. I have written and preached and taught the greater safety of ether, and I have lived to see it paramount as the reigning anæsthetic.

Let me now speak of

Instruments of Precision and their Introduction into Practice.

Here I would give precedence to those used for anæsthetics. They are one of the earliest, the most universally employed, and the most effective aids to surgery, and in fact to medicine, which includes surgery, of any instrument ever devised.

When I became a student at King's College in October, 1852, Dr. Snow was working out the science of chloroform administration, and he had invented, I believe, the first mechanism for its administration, "Snow's Inhaler." At that time the only instrument of precision in general use, even then struggling to assert itself, was the stethoscope. Next came the ophthalmoscope. In my third summer session, May, 1855, at the height of the Crimean war, I became clinical assistant to Sir William Bowman at Moorfields, *vice* Hulke, who had gone out with the team of the picked young surgeons of London to work in the military hospitals of the Crimea. At that time the ophthalmoscope was being introduced to the staff and pupils at Moorfields by Dr. Bader, a refugee—Polish, I think. The invention of the instrument was by a German, and the Germans were ahead of England in its use and had already published an illustrated work by Jaeger, of Vienna.

But the ophthalmoscope was destined to have a wider field. It occurred to a young physician of Leeds, Clifford Allbutt, that it must come into use by the physician. He took every opportunity of mastering its use, including the field offered by the West Riding Asylum, thanks to the collaboration of Crichton Browne. Allbutt finally brought the matter before the profession by publishing a work "On the Ophthalmoscope in Medicine." (Macmillan, 1871.)

Clinical thermometry.—After a while the clinical thermometer comes on the scene—two long thermometers in a "sesquipedalian" box, about 12 inches long, which the poor doctor had to carry about under his arm. Clifford Allbutt again came to the rescue. Realising the enormous

possibilities of the instrument, and the necessity of easy portability, he devised, with the aid of Mr. Reynolds, of Harvey and Reynolds of Leeds, the short thermometer that could be carried in the waistcoat pocket, and he got a scientific friend to invent an index that would register the temperature. Allbutt also contributed to spread the use of the instrument by using freely as a handbook and for quotation "Clinical Thermometry," by Wunderlich.

Hypermetropia and astigmatism.—Then followed closely the discovery, aided by the ophthalmoscope, of optical defects that could be corrected by carefully selected lenses, hypermetropia, and astigmatism, worked out by Donders, of Utrecht, the great Dutch scientist, whose work on optical corrections was published in translation by the Sydenham Society and so brought before English-speaking ophthalmologists.

Laryngoscope.—Whilst the ophthalmoscope and thermometer were "making good" in England there arose another instrument of investigation, the laryngoscope. This came before the profession in another volume of the Sydenham Society—a translation of Czermach's work. Our early work was difficult, as we had no electric light, no local anaesthetics, no specially designed instruments. Of early successes two were very encouraging: one a sixpence lying flat in the larynx; the other a flat piece of bone lying vertically. The removal of these was at that time a veritable triumph.

Endoscope.—Following the laryngoscope came the endoscope, invented by M. Dieulafoy and introduced into Britain by Dr. Cruise, of Dublin. Dr. Cruise had improved the lamp, but its use was cumbersome and difficult. I had one conspicuous success. A patient who was being treated for stricture consulted Dr. Allbutt. He suspected stone, and sent him on to me. Having sounded and felt a calculus, I examined with the endoscope and saw several calculi. Ten were removed with a vesical pump. The man was cured. This endoscope did not make much progress. The invention in due time of an electric illuminator made all the difference, and now it is a recognised part of the conditions of surgery.

Hypodermic syringe.—I now come to the last of my special selection of instruments of precision, the hypodermic syringe, in reference to which this portion of my paper shall conclude with a quotation from the introductory address in 1867. I had then been for three years surgeon to the infirmary, working with my colleagues in the old infirmary under what would nowadays be looked upon as insuperable disadvantages.

"The increasing confidence in the physical modes of exploring the human body renders us less satisfied to remain in doubt when we can obtain certainty. We are approaching the time when we shall shrink from treating loss of voice without using the laryngoscope, or disease of the brain without exploring the optic nerve with the ophthalmoscope, or disease of the bladder without the aid of the sound or the endoscope. Thus prepared to demand exactness in observation, there has been granted to us one of those discoveries which, like chloroform, mark an era in our history—*hypodermic injection*. Valuable though this mode of treatment may be in its command over pain, it is still more important to the advance of science in the field of inquiry it has opened out, not only for testing the value of medicines, but also for searching into the nature of morbid processes themselves. When we see a neuralgia of long standing cured by one injection of morphia; when we see the same remedy visibly restoring to health congested vessels of the conjunctiva; reducing unnatural heat, not of the whole body, but of a suffering portion of it; lessening the swelling of an inflamed joint; arresting vomiting depending upon a lacerated brain, or upon peritonitis or suppressed menstruation—I speak of the things that I do know—we must feel that we have much to revise and much to learn as to the intimate nature of morbid processes by the light of our new power."

This was said 53 years ago.

Leeds University Address, 1888.

My next Introductory Address was given at the Leeds University 21 years later, in 1888. I had then been for four years consulting surgeon, with the right to use six beds for cases of my selection. The address was delivered at two weeks' notice to fill the gap made when Lord Lister was suddenly unable to fulfil his undertaking, and so it was given under disadvantages. Speaking of the elaborate arrangements for turning out an efficient practitioner I urged that—

"There was a part, and that no small one, in the training of a skilful practitioner which neither curriculum, nor lectures, nor examinations could secure. That part might be called self-education—the earnest seeking after every opportunity of seeing, of observing, and of doing; the training of their eye not only to see disease, but to observe its effect upon the countenance, the manner, the character of the patient, and, beyond the patient himself, the effect upon others—parents, children, friends, dependants—so that their minds might grasp the whole situation, and enable them to discharge in the fullest sense their duties as medical advisers; the determination to use every opportunity of watching illness, of discharging small duties about the sick, of training the hands and touch and mind to handle gently, and, when obliged to give pain, to give as little pain as possible. And not least of the faculties of immense importance to a medical man was tact. That was partly the result of natural qualities, partly the

result of training of the observation. Tact implied the power of observing and estimating the effect of their own manner and words upon others, combined with judgment to perceive what was the best thing to do, with the right feeling to enable them to act unselfishly in the interest of another."

King's College Address, 1908.

The third address, 20 years later, was delivered at King's College, London, where 54 years before I had entered as medical student, and had listened to the opening address. This address was essentially a "retrospect," a record of what existed when I was a student. But in referring to the advance of surgery I quoted from the records of operations at the Leeds Infirmary, with which, of course, I was familiar. From this summary I take two or three examples of steadily diminishing fatality.

The comparisons are taken in half decades, beginning in 1861 and ending 1905.

Ovariectomy.—In the 20 years 1860–80, out of 86 cases 1 in 3 proved fatal; in the 5 years 1901–05, out of 105 cases 1 in 21 proved fatal.

Radical cure of hernia.—In the 5 years 1880–85 the fatality was 1 in 11; in the 5 years 1885–90, out of 790 cases the fatality was 1 in 197.

The "Family Doctor."

In conclusion, let me say a few words as to the "family doctor." I will not call him a general practitioner, a term which implies the technical side of our profession. A family doctor who is all this—a competent practitioner of medicine—but, in addition, may be all that is implied in the words of a colleague at a recent medical dinner: "The practice of medicine is a personal, individual, intimate thing." Knowledge of this can only be acquired by contact with human beings in sickness and health, in poverty and well-being. Such a man should enter a house as a longed-for friend and a kindly and sympathetic adviser. Many such have I known and treasured as personal friends—and not least—among the noble corps of country doctors.

COLONIAL HEALTH REPORTS.

Bahamas.—Mr. F. C. Wells Durrant, acting Colonial Secretary, in his report for 1918–19, estimates the population at 60,082. The birth-rate was 34.3 and the death-rate 15.8 per 1000. Notwithstanding an epidemic of chicken-pox, from which very few fatalities resulted, the public health of the colony was, on the whole, good. There were a few cases of typhoid fever. Owing to a vigorous and stringent quarantine against incoming vessels, the colony was fortunately spared the ravages of Spanish influenza. Dr. A. H. B. Pearce assumed the duties of chief medical officer in March, 1919, in succession to Dr. J. Baird Albury, who had been acting on half salary for a considerable time. There were 765 admissions to the General Hospital (which comprises, besides the hospital proper, the Victoria Jubilee Infirmary, the lunatic asylum, and leper wards), making a total under treatment during the year of 900, of whom 315 were discharged recovered, whilst 250 were relieved and 131 died.

Gambia.—A report prepared by Mr. B. A. Finn, acting Assistant Colonial Secretary, reporting on the Blue-book for 1918, states that in 1911 the population of Bathurst was given as 7700 and that of the Protectorate as 138,401. It is probable that the population of Bathurst has increased but little since that date. On the other hand, there is good reason to believe that the population of the Protectorate is at least 30 per cent. greater. No accurate information is obtainable with regard to births and deaths in the Protectorate. The total number of Europeans resident was 122, of whom 112 were males and 10 females. There were 6 deaths amongst all these, from pneumonia and influenza, and no births. Amongst the native population of Bathurst the birth-rate was 34.1 and the death-rate 71.4 per 1000. There were over 300 deaths in Bathurst and 7800 in the Protectorate from the influenza epidemic which swept over the whole coast in the latter months of the year. Infantile mortality was at even a higher figure than usual. Out of a total of 263 births in Bathurst there were 50 stillbirths and 138 deaths of infants of less than 1 year of age; there were also 89 deaths of children over 1 and under 5 years of age. Malarial fever was the most prevalent disease, and pneumonia was more prevalent than usual, but there was no case of yellow fever, small-pox, or plague, and only 1 case of typhoid fever. The total rainfall for 1918 was 54.03 in., being greatly in excess of the average for the past ten years, which was 33.45 in. The highest recorded temperature was 101° F. (May 20th) and the lowest 48° (March 16th). The highest mean temperature in any month was 93° and the lowest 55.1°.

Gold Coast.—Captain C. E. Cookson, Assistant Colonial Secretary, is responsible for the report on the Blue-book for 1918, which gives the total population of the Gold Coast and its dependencies as 1,503,386. The number of Europeans resident in the colony during 1918 was 1823, comprising 515 officials, 681 employees of trading firms, 578 employees of

mining companies, and 49 missionaries. The death-rate amongst Europeans in the colony was 30.7 per 1000, as compared with 12.43 in 1917; the invaliding rates per 1000 for the same periods were 55.4 and 52.49 respectively. Of the 9 deaths which occurred amongst European officials in the colony and its dependencies 2 were due to blackwater fever and 4 to influenza. The death-rate of European officials fell from 15 per 1000 in 1917 to 11.6 per 1000 in 1918, and but for the deaths from influenza would have fallen to 3.8 per 1000. Of the 50 deaths of European non-officials 4 were due to blackwater fever, 25 to influenza, and 1 to yellow fever. No means exist whereby accurate statistics relating to the health of natives can be obtained. Treatment was given in 3181 cases of malaria, 416 of dysentery, 356 of pneumonia, and 239 of tuberculosis. In all 58,666 cases of disease were treated during the year, and of these 524 proved fatal. In September, 1918, an outbreak of influenza occurred on the coast line and spread rapidly through the colony and its dependencies. Only a very rough estimate can be made of the number of deaths caused by the pandemic, but it must have been very great. In the 7756 cases treated in the hospitals there were 204 deaths, giving a case mortality of 2.6 per cent. Assuming three-fourths of the population to have been attacked and the case mortality-rate the same the total number of deaths would be 30,000. The outbreak of small-pox that occurred in the Northern Territories in 1917 continued in 1918, when 88 cases were reported with 24 deaths. Ten cases of sleeping sickness were treated during the year. Of 17 cases of blackwater fever treated 4 proved fatal, and of 5 cases of yellow fever all resulted in death. The climate, though hot and damp, is cooler than that of most tropical countries situated in the same latitude. It is not in itself unhealthy, but an evil reputation has been earned for it in the past by the prevalence of mosquito-borne diseases, against which all possible precautions have constantly to be taken. The Gold Coast is peculiarly free from many of the discomforts associated with tropical countries; hot nights and intense heat by day are the exception rather than the rule, while insects are comparatively unobtrusive. The efforts of the sanitary and medical authorities in promoting hygiene and treatment of disease continue to exercise a beneficial effect on the general health of Europeans.

POISONOUS SHEEP-DIPS.

A NUMBER of deaths have occurred among sheep as a result of the use of poisonous dips during the present dipping season. There has always been a certain mortality with the use of arsenical dips, but the cheapness of arsenic as a drug, and the fact that it and its preparations have been used both internally and externally for skin complaints in animals for many years, perhaps account for the vogue it enjoys and the reluctance with which its use is relinquished. The advances in the science of therapeutics are but slowly recognised by the wholesale makers of proprietary remedies like sheep-dips, and really some legal measures and regulations want bringing forward to do away with the dangerous treatment and wholesale and indiscriminate drugging of animals and the subjecting of them to the action of remedies of out-of-date, crude, and mediæval form. In the case of sheep-dips lime and sulphur, cresol, lysol, and bacillol are all as effective as arsenical preparations, and much safer.

A GERMAN SURGICAL DIRECTORY.

WE have received from the publishing firm of Johann Ambrosius Barth in Leipzig an octavo volume of 288 pages, entitled "Deutscher Chirurgen-Kalender," being a directory of German surgeons and orthopaedists, containing short biographical and bibliographical details. The directory has arisen, it is stated, from the need felt for a handy book of reference giving the present and past professional and literary activities of surgeons from which to draw correct conclusions and avoid confusion of names. Curiosity in regard to the career of this or that colleague after five years of war is intended to be satisfied. Names are included from German-speaking Austria and Switzerland, and from the Scandinavian countries. The omission of many well-known names is explained by the uncertain political conditions. The directory is an entirely new compilation, based upon the answers to a circular sent out. The editors are Professor August Borchard, one of the editors of the recent German War Surgery, and Dr. W. v. Brunn, privat-docent for the history of medicine in Rostock. The price is M.36.

LEFT-HANDEDNESS AND MIRRORED WRITING.

In this reprint of a paper from *School Hygiene* Dr. James Kerr deals with a bypath which borders on medical fields. Dr. Kerr attempts to show that left-handedness presents two varieties, what he calls pure left handedness associated with right brain development and normal mentality, and the variety whose fingers are all thumbs, denoting want of cerebral specialisation in dexterity. He thinks that the supposed association of stammering with correction of left-

handedness is unproved and is due to mis-read statistics, also that the idea of ambidextral culture developing fresh centres on the right side of the brain is physiologically unsound. The subjects of dextrality and mirrored work are very thoroughly discussed, especially from the standpoint of the school doctor. Dr. Kerr is a recognised authority on such questions and the paper is a valuable addition to the literature of the subject.

R. W. P.—Any opinion would be useless unless based on careful local examination.

Medical Diary.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

LONDON HOSPITAL MEDICAL COLLEGE.

MEDICAL UNIT, in the Clinical Theatre of the London Hospital, E.

A Course of Twelve Lectures on Neurology, open to Students and Graduates of the London Hospital and other Schools—

TUESDAY, August 17th.—2 P.M., Lecture XI.:—Dr. Riddech: The General Treatment of Disorders of the Nervous System.

WEDNESDAY.—2 P.M., Lecture XII.:—Dr. Thompson: Treatment of Paraplegia.

WEST LONDON POST-GRADUATE COLLEGE, West London Hospital, Hammersmith, W.

MONDAY, August 16th.—12.15 P.M., Dr. Burnford: Pathological Demonstration. 5 P.M., Mr. MacDonald: Hæmaturia.

TUESDAY.—10.30 A.M., Surgical Registrar: Demonstration of Cases. (Surgical Wards.) 2 P.M., Dr. Burnford: Demonstration of Medical Cases. (Medical Wards.)

WEDNESDAY.—11.30 A.M., Mr. MacDonald: Demonstration of Cystoscopy. 4.30 P.M., Dr. Owen: Demonstration of Medical Cases. (Lecture Room.)

THURSDAY.—10.30 A.M., Dr. Simson: Gynæcological Demonstration. 4.30 P.M., Mr. B. Harman: Purulent Conjunctivitis.

FRIDAY.—12.15 P.M., Dr. Burnford: Applied Pathology.

SATURDAY.—12 noon, Mr. Sinclair: Surgical Diseases of the Abdomen.

Daily:—10 A.M., Ward Visits. 2 P.M., In-patient, Out-patient Clinics and Operations.

MALE LOCK HOSPITAL, Dean-street, W.

MONDAY, August 16th, WEDNESDAY, AND FRIDAY.—5 P.M., Dr. C. Russ: Demonstration of the Treatment of Gonorrhœa by Electrolysis.

CANCER HOSPITAL, Fulham-road, S.W.

Clinical Lectures on the Diagnosis and Treatment of Cancer.

TUESDAY, August 17th.—4.30 P.M., Sir Thomas Horder: The Value of Combined Methods of Treatment in Inoperable Cancer.

A Lecture

ON BODY AND MIND.

Delivered at the Thirty-first Congress of the Royal Sanitary Institute held at Birmingham on July 19th to 24th, 1920,

BY SIR FREDERICK W. MOTT, K.B.E., F.R.S.,
M.D., F.R.C.P. LOND.

MR. PRESIDENT AND GENTLEMEN,—When I was asked by the Royal Sanitary Institute to give the lecture at the meeting to be held in July in Birmingham I considered what subject I could deal with to the best advantage from my own personal experience—as physician for 30 years to a large London hospital, as pathologist to the London County Council asylums for 25 years, and as chief neurologist to the Neurological Clearing Hospital, London, during the whole of the war and since. “Body and Mind” was the subject I selected, for this reason—that no real progress can be made in the study of the mind, in health and disease, if either the mental or the bodily part of man’s nature is studied apart, one to the exclusion of the other, for they are indissolubly united.

The experience of the war and its aftermath has taught us one great lesson. That there is a large number of men and women who, owing to an inherent or acquired neuropathic temperament, are unable to make or sustain the necessary mental adjustments to enable them to be of military or civil worth in the military or civil occupations in which they have been or are at present engaged.

There is an After-Care Association which does admirable work in looking after the feeble-minded and those who have been discharged from asylums, but what I think is of more importance is a Before-Care Association, to help the great army of inefficient sufferers with no obvious bodily disease or defect; such are individuals suffering with neurasthenia, anxiety neurosis, psychasthenia, mild cases of mental depression and mania, hysteria, hypochondriasis, and epilepsy; also particularly those who are still suffering from the effects of shell shock, hysteria, and other war neuroses.

The functional paralyses, tics, tremors, blindness, deafness, mutism, and other functional disabilities occasioned by the stress of war and emotional shock in neurotic or neuropathic individuals were, from a psychological point of view, biological protective reactions of the emotion of fear by unconscious suggestion, affording a mode of escape from an intolerable situation. The intolerable situation I refer to is trench warfare. Since these functional disabilities were produced by suggestion, they could be, and were, cured by contra-suggestion and persuasion. I have been astonished at the ignorance of many of my professional brethren regarding the diagnosis and treatment of these functional cases.

At the Maudsley Hospital we have cured hundreds of soldiers and pensioners in a few minutes, a few hours, or a few days, who had been in hospitals and convalescent homes months or years, and who, owing to ignorance of diagnosis, had been treated for organic disease by massage and electricity, carried out frequently by sympathetic ladies on the “poor dear” principle, under the direction of medical practitioners unacquainted with neurological and psychological medicine.

Again, surgeons have treated numbers of functional orthopaedic disabilities by the application of expensive and elaborate apparatus, often of the most ingenious nature. The result of their ingenuity, however, was only to suggest to the mind of the patient organic disease, and firmly instal the idea of the existence of a permanent disability and pension for life. The existence and cure of this class of functional case is certainly as old as Christianity, and probably much older. Functional neuroses and psychoses exist among savages and primitive peoples in all parts of the world, frequently taking on a local colour.

No. 5060

NO NEW NERVOUS DISEASE IN WAR NEUROSES.

The war has produced no new nervous disease; it is the same hysteria and neurasthenia which neurologists knew before the war, and which were curable by the same methods. A fact brought home to all those who have had the care of war psycho-neuroses is that the signs and symptoms of hysteria and neurasthenia of men who have been to the front and have been invalided home (except those in which there has been definite evidence of cerebral or spinal commotion or concussion, burial, or gassing) in no way differ essentially from the signs and symptoms of hysteria and neurasthenia of soldiers who have never been out of England. In support of this statement I may mention that I have seen both hysteria and neurasthenia arise from the fear of conscription, or, having been conscripted, an hysterical crisis, contracture, or paralysis has occurred when it became known that the conscript would be in a draft for general service abroad.

Again, inoculation has been followed by hysterical paralysis. I may mention one case which was recently sent to me. He was inoculated in March, 1915, and a quarter of an hour after he lost the use of his legs. He was sent to various hospitals and brine baths. He was then boarded out of the army and received a pension of £2 12s. per week for himself, his wife, and family. He was sent to me by the Chelsea Pensions Board, arriving with crutches and a contracted knee. He was induced by contra-suggestion and persuasion to walk in half an hour, and in a week was discharged cured.

I have observed that hysterical manifestations, especially mutism, paralysis, and contractures, are much more frequently met with in the men than in the officers. The latter more often suffer with an anxiety neurosis.

SEVERE SHOCK MAY INDUCE HYSTERICAL MANIFESTATIONS IN A NEUROPOTENTIALLY SOUND INDIVIDUAL.

The great importance of the inborn or acquired neuropathic tendency in the production of the symptoms and signs of hysteria and neurasthenia cannot be over-emphasised. At the same time it must be admitted that shock, and by this I mean not only commotional but emotional shock, due to terrifying or horrifying conditions of war, may have induced hysterical manifestations in a neuropotentially sound individual, in fact, in a soldier who, by his record, had shown that he was neither of a timid disposition nor had any neuropathic tendency.

Automatism and somnambulism, like the hypnotic state, is caused by a dissociation of the field of consciousness from perpetual stimuli, and is regarded as a characteristic symptom of hysteria. Yet cerebral commotion, caused by the bursting of a large shell, may, as the following case shows, bring about in a neuropotentially sound individual a condition of automatism:—

Battle Hypnosis.

“A captain was admitted under my care, and gave the following history: His company had dug themselves in, in a wood; he went out into the road to see if a convoy was coming, when a large shell burst near him. It was about 2 o’clock in the morning, and quite dark; about 4.30 A.M. it was quite light, and he found himself being helped off a horse by two women, who came out of a farmhouse. He had no recollection of anything that happened between the bursting of the shell and this incident.”

The anxiety neuroses and psychasthenia with obsessions which have been and still are affecting so many people, both in military and civil life, are neuropathic functional disorders which cannot thus be rapidly cured by suggestion and persuasion. The sufferers with these functional disorders are frequently quick-brained, intellectual men and women in all grades of society, and these are suitable subjects for psychotherapy. The doctor who has a knowledge of psychological medicine and makes it his business to study the desires and motives which determine conduct, and who is able to establish that sympathetic relation with his patient whereby he gains their confidence, is able to uproot from the mind an anxiety causing a mental conflict, for which the patient is continually, but unavailingly, striving to make adjustments. The

continuous mental conflict from which the patient affected by an anxiety neurosis suffers goes on during sleep, exhausting his nervous energy and leaving him unrefreshed, depressed, and despondent on awaking. This mental conflict which the experiences of the war and the dreams of soldiers of their terrible experiences have brought home to us in a vivid manner reacts unfavourably upon all the bodily functions; thus a vicious circle is established in which the *joie de vivre* can only be restored by removing the cause of the anxiety and improving the bodily health. Now that the terrors of the war and their effects on the mind are passing away we have the aftermath of the war and the persistence of a widespread anxiety neurosis occasioned by a contemplative fear for the future of self, of wife and family, in a large number of officers and men with an inadequate or deferred pension and no employment. Many of these officers and men joined up early in the war, before entering an occupation or completing their training in it. No wonder, then, that a widespread spirit of discontent exists among ex-Service men, in spite of the fact that rather belated endeavours in mental hygiene are being made by the Government to establish Training Centres for education, re-education, and social rehabilitation. The nation is only beginning to realise that we can never go back to the pre-war conditions.

OBJECTIVE PSYCHOLOGY.

Before, however, I proceed to discuss some of the practical problems of mental hygiene, I will briefly consider the modern trend of objective psychology.

The furniture of the mind is the memory of the experiences of our life and of the bonds that unite them; there can be no mind without memory, and no memory without body. The furniture of the mind of primitive man consists largely of the memory of experiences connected with the primal instinctive activities of nutrition, by capture of food, of self-preservation and avoidance of pain, of reproduction, and of the instinct of the herd. The civilised man is able not only to store up and utilise his own experiences, but by means of language and abstract thought, to associate these experiences with those of innumerable other human beings, who live and have lived, and thereby to reason on a much higher plane, and utilise his psychic energy in a multitude of refined ways for the ultimate ends of the primal instincts.

The Freudian school of psychologists assert that all psychic energy has its roots in sexual instinct, and they maintain that the sexual life of the individual begins its development at birth or even before birth. Dr. W. McDougall, in the last edition of his "Social Psychology," has added a chapter on the "Sexual Instinct," and he now recognises that sexual experience and conduct afford the most obvious support of the biological theory. He remarks that the energy of the sex impulse, if it is not expended wholly in its own channels of expression, may reinforce intellectual activities, and thus function in situations that make no direct appeal to the instinct. Such indirect utilisation of this primal instinct as a great source of psychic energy, available for other than purely sexual activities, is the process which Freud terms sublimation.

McDougall recognises the general truth of this Freudian doctrine, without, however, committal to the acceptance of all, or, indeed, any, of the other doctrines of the "sex impulse" of Freud, and I am in agreement with him that the theory of the sex instinct serving as the great source of psychic energy is a fundamental principle of biological psychology. The psychic energy derived from the sex instinct is the *élan vitale* which bursts forth in youth, and is so well and poetically described by Shakespeare in *Romeo and Juliet* in the lines:—

"My bosom's lord sits lightly in his throne;
And all this day, an unaccustomed spirit lifts me
Above the ground with cheerful thoughts."

Every intelligent human being is continuously engaged in the practical study of psychology, although he may be as unconscious of the fact, and, moreover, as surprised when he is told, as Molière's "*Bourgeois Gentilhomme*" was, when he discovered that he had been talking prose all his life. For do we not all judge

by analogy the feelings and motives of others by observing their conduct, their facial expression and gestures, a universal language of the emotions which is often a truer indication of the passions and motives passing in the minds of our fellow-men than is revealed by speech, which often, as Talleyrand said, was given to man to hide his thoughts.

All the desires and impulses which move human beings to action have their source of psychic energy in the four primal animal instincts of nutrition or capture of food, self-preservation, the sexual instinct, and the herd instinct. All feelings, thought, and action, whether individual or collective, have their source in these essential springs, out of which flow the mental streams and rivers of individuals and nations.

In the higher animals there are few purely instinctive modes of behaviour unmodified by intelligence and by habits acquired under the guidance of intelligence and imitation. Man, owing to the great development of his brain, his erect posture, strength, and symmetry of the body, together with the hand, as instrument and instructor of the mind, has been able to make an infinite variety of sensory-motor adjustments and reactions to environment for the conservation of the individual and the preservation of the species. By the acquirement of refined means of inter-communication of his thoughts and feelings, firstly by a language of emotions and later by an articulate language of intelligence and abstract thought, he has, within comparatively recent times, built up a social heritage. But it is doubtful whether this has been associated with any structural change or increased development of the brain; although without this social heritage he could never have attained the power he has obtained of controlling the forces of Nature.

Compared with countless ages man has existed on the earth feeling, thinking, and acting in response to the gratification of the desires of these primal instincts, the oldest known civilisation is but as yesterday to many years.

EVOLUTION OF THE SEXUAL INSTINCT.

When we realise that the intellect of man in the process of evolution has within comparatively recent times been superimposed upon this strong animal instinct, the gratification of which is attended with intense pleasure and its repression with mental pain, and, further, when it is considered that social progress and conditions of modern civilisation tend more and more to frustrate the end of this strong instinct which Nature designed for the preservation of the species, a disharmony arises which not only endangers the happiness and contentment of mind of numbers of civilised human beings, but also threatens the race with decay. Seeing that culture and civilisation cannot suppress this vital force of the sex instinct, its control has been, is, and must ever be, a difficult problem for the race; and as McDougall says, the difficulty increases rather than diminishes with every forward step of civilisation and every increase of far-sighted intelligence over the immediate promptings of human nature.

The herd instinct in man is intimately associated with the sex instinct in this problem, for the bond of union of the herd is a willingness on the part of each member to sacrifice individual interest and life in the interests of the herd; self-preservation thus becomes secondary to preservation of the species. This is well exemplified in the social instincts of bees and ants and gregarious animals.

Primitive man and still more civilised man, have evolved social usages and customs connected with the sex instinct which have become traditions in the tribe or race, allegiance to which serves as a further bond of union, and every individual who desires to be esteemed and his conduct approved, must conform to these traditional customs and usages and the penalty of thinking rationally, of thinking differently, and of thinking and acting independently is to court disapproval, disfavour, or of being thought not respectable. Yet, as Maudsley says, "How inestimable, then, the service rendered to mankind by the few who can think, and, thinking, do differently from the herd." A truth which Prince Henry appeared to appreciate when he sarcastically

complimented Poin: "Thou art a blessed fellow to think as every man thinks: never a man's thought in the world keeps the roadway better than thine." (2nd Part *King Henry IV.*, Act 2. Sc. 2.)

But what is the solution of this sex problem? Early marriage is what Nature intended, and this is poetically expressed in the philosophy of Shakespeare when, in the Sonnets, he is advising a young nobleman to marry and propagate thus:—

"Upon the earth's increase why shouldst thou feed
Unless the earth with thy increase be fed?
By law of Nature thou art bound to breed
That thine may live when thou thyself art dead.
And so in spite of death thou dost survive
In that thy likeness still is left alive."

Religions and traditions from time immemorial have centred around the sex instinct; this is strikingly illustrated in the worship of the Virgin and Child, symbolic of chastity and the tender emotions.

All the higher, as well as the baser passions and sentiments have their source in the sex instinct. Painting, sculpture, music, romance, literature, and the drama owe their inspiration and fervour to the sexual passion; yet social traditions and customs of the herd have, in the past, conspired to throw a veil over the tree of life, the openly expressed knowledge of which has been regarded as the forbidden fruit. Social conditions tend to repress the supreme end of this instinct, especially in women. When this happens the psychic energy of the instinct is not suppressed; it may be repressed and cause a silent current of sexual desire and passion which, although not manifest to the external world, nevertheless occupies a large place in the conscious and subconscious self, causing mental suffering, with its special emotional tone which finds outward expression in æsthetic forms or religious observances.

The aim and object of a civilisation should be, then, to encourage early marriage of people of civic worth by provision of houses, of a wage or income sufficient to maintain a wife and family, and by the removal of all restrictions to suitable marriages and the upbringing of children. It is certain that overcrowded dwellings and domestic discomfort lie at the root of many social evils. With the present conditions of our social system, however, marriage is possible only for a certain proportion of the population, but the sex instinct cannot be suppressed. In some the psychic energy may be diverted into other channels—e.g., the young may be encouraged to utilise the energy in sport, work, and intellectual occupations, but in spite of such diversion, moral teaching, and fear of consequences, large numbers of both sexes cannot control the impulse and do not remain chaste, consequently promiscuous intercourse and prostitution, with all its attendant evils, continue. It is of no use hiding this fact; the war has clearly shown the truth of this statement. Venereal disease was, and is, still raging in our midst. A hopeful change, however, came over the public, in a great measure due to the fatal emergencies of the war, backed by a strong expression of opinion from our Colonies, that prophylactic measures had to be taken to prevent this scourge in our midst becoming worse.

The "Hidden Plague."

Seven years ago venereal disease could not be discussed in the public press, in spite of the fact that our hospitals, infirmaries, asylums, and institutions for the deaf, the blind, the paralysed, the imbeciles, and the idiot contained a large proportion of inmates suffering with incapacitating or fatal disease directly or indirectly due to venereal infection. And in spite of the fact that large numbers of innocent women and children were the sufferers, and in spite of the knowledge that a large proportion of the abortions, miscarriages, children born dead, as well as sterility in women, was the result of infection. The public had not yet learned to follow Dr. Johnson's adjuration to clear the mind of cant. Then came the International Medical Congress in London, and the discovery of a new method of treatment of what had been euphemistically called in the press the "hidden plague." Fortunately to be hidden no longer, for a Royal Commission was appointed, of

which I was a member, and it was proved that the registration of causes of death, which had been relied upon by politicians, instead of revealing the fatal effects of venereal disease, obscured them. The evidence showed that 1 in 10 of the adult male population had been infected with syphilis, and a far larger percentage with gonorrhœa. The evidence proved that there was not an organ or tissue of the body which was not liable to be diseased on account of it, and that its most incapacitating and fatal effects fell upon the most vital structures—viz., the heart, the blood-vessels, the spinal cord, and the brain. Statistics proved that 10 per cent. of persons infected, in spite of treatment, had subsequently died of softening of the brain or other nervous disease, after having been paralysed or demented for years.

It was hoped that the recommendation of the Commission, supported later and energetically carried out by the National Council for Combating Venereal Disease, would, by the establishment of early ablation treatment centres throughout the kingdom, be able to deal effectively with venereal infection and prevent the spread of the disease. Unfortunately, many borough councils and county councils, including the London County Council, do not regard these early ablation treatment centres as practical, or at any rate refuse to adopt this means of combating venereal disease. Numbers of eminent medical men, some of whom were originally members of the National Council, realising the impracticability of early treatment centres, desire to see the same method of immediate self-disinfection adopted for the civil male population, as was successfully practised in the army by Sir Archdall Reid at Portsmouth. The treatment he employed was a simple disinfectant—1 part in 1000 of permanganate of potash.

Public opinion has changed, for a whole column of a recent issue of the *Times* was given to the subject "Venereal Disease, Self-Disinfection Problem. Deputation to the Minister of Health."

The President of the Society for the Prevention of Venereal Disease, Lord Willoughby de Broke, read the following resolution of the Society:—

That inasmuch as the Ministry of Health has failed, and public bodies (including the London County Council) have declined, to provide the means of delayed disinfection against venereal disease at ablation centres, this meeting calls upon the Ministry of Health and upon local authorities to instruct all qualified chemists to sell such means of immediate self-disinfection against venereal disease as may be approved from time to time by the Ministry of Health or by medical officers of health.

Whilst giving a sympathetic hearing to the deputation, the Minister expressed the opinion that before he adopted any of the suggestions submitted to him he had to be satisfied that any change he made was in the right direction. The department was anxiously watching the experiments that were being conducted, and he would seriously consider the proposals put forward for self-disinfection.

It is argued that there is no evidence of a recent increase of venereal disease, but that larger numbers of people attend the treatment centres; and in support of this fact it is claimed that general paralysis of the insane and locomotor ataxy, both of which are, in all cases, the direct result of the syphilitic organism invading the nervous system, have not shown an increase; but this argument is entirely fallacious, for the average time after infection, when these diseases manifest themselves, is ten years. There is strong evidence to show that the reason why these late fatal syphilitic diseases of the nervous system are so common among civilised people is that the organism has become modified owing to the widespread use of mercury in treatment, and seeks the nervous system, where it is protected from the effects of the drug. These diseases, general paralysis and locomotor ataxy, are seldom met with in countries where syphilis has been recently introduced.

The reasons advanced why this scientific knowledge of early disinfection should not be employed is the fear that it will increase immorality. Of course, every right-minded man would say that either chastity or marriage is the only safeguard, but I have given strong

reasons why, in the present social conditions of our people, we can hope for neither of these moral conditions becoming universal. Why should we wait till the syphilitic organism has entered the body before attempting to destroy it? Every delay diminishes the hope of eradicating the disease and preventing its spread, and we have to consider the innocent women and children, the dead and the unborn hundreds of thousands of babies. If in other diseases we, as doctors, make every endeavour to destroy the germ before it can colonise in the body and cause a constitutional disease, why not in this disease? I appeal, therefore, to this Sanitary Congress to support the propaganda of the Society for the Prevention of Venereal Disease for the following reasons:—

(1) If the experience of the war has shown that it is impossible for numbers of men to be sexually moral, is it not desirable that they should be made to feel the responsibility of contracting the disease and transmitting it to innocent people? The only practical way in which I can see this can be done is by instruction in immediate self-disinfection.

(2) Early treatment centres are not likely, for obvious reasons, to be used by numbers of men after exposure to infection, and again, there will often be fatal delay before the treatment centres can be reached.

(3) The cost of self-disinfection is borne by the individual, whereas the taxpayer has to pay for treatment centres.

I have seen, in the London asylums, thousands of men and women die from general paralysis of the insane. For 20 years I have endeavoured to make the profession and the public realise that if there were no syphilis there would be no general paralysis or locomotor ataxy. To show the effects of syphilis in the production of fatal and incapacitating nervous disease and paralysis I will cite an experience of only last week. I went to a London infirmary to give a clinical lecture to my class on nervous diseases then being treated in the institution. There were five cases among the women suffering with severe organic nervous disease, and four out of the five were due to syphilis. The frequency with which syphilis acts as a cause of fatal and of disabling organic disease is known to every hospital physician.

The destructive effects of syphilis on the brain is the best example I can offer of the effects of bodily disease upon the mind. The loss of mind is proportional to the destruction of the hemispheres of the great brain, which is the anatomical substratum of consciousness and memory, and in the last stages of which the sufferer with this disease leads a mere vegetative existence.

THE HERD INSTINCT AND THE SUGGESTIBILITY OF MAN.¹

The gregarious instinct is to follow a leader. Sometimes this is advantageous, sometimes disadvantageous, both in peace and war. The dancing mania of the Middle Ages was a striking example of the effects of suggestion; we see it every day in crowds that will collect at the most trivial incident; indeed, if a person stood in the street and gazed up at the sky, although nothing was to be seen, his action would soon be imitated by numbers of people. In war, this suggestibility may be advantageous or the reverse. A British general is said to have remarked that 10 per cent. of a regiment would fall down or run away, 10 per cent. would follow you to the gates of hell, and the remainder would follow either. It is obvious, therefore, that the men with nervous or timid temperaments are a positive danger, and it was for this reason doubtless, that some of these men, in the earlier years of the war, were tried by court-martial and shot for cowardice. Conscription of large numbers of neurotically unfit men, who never could make soldiers, was subsequently found to be a mistake. Moreover, it was found to be a mistake to send officers and men back to the front who had been sent home suffering with shell shock, neurasthenia, or hysteria. Nervous or mental inferiority was

not considered sufficiently as a cause of rejection for general service, and the nation is paying a heavy price in the matter of pensions in consequence thereof. Does not this clearly show that some psychological training of medical men is necessary, especially when we remember that one-third of the unwounded in 1917, discharged as unfit for service, were men suffering with war neuroses and psychoses? It also shows what experienced neurologists know, that a large proportion of the civil population are potential neuropaths or psychopaths, and that this branch of medicine should be taught more efficiently.

I am glad to see that the Royal Sanitary Institute has recognised the importance of psychiatry in sanitary science by initiating a discussion on psychiatric clinics. We have learnt that a mentally sound individual does not become insane by the stress of war; nor does stress produce mental deficiency. The war has taught us that the neuroses, insanity, epilepsy, and mental deficiency are inborn, and the stress and strain of war have merely revealed or accelerated their onset. A long experience as pathologist to the London asylums and a study by a card system of 4000 near relatives, who have been or who are still inmates, showed conclusively the importance of the hereditary factor. The experience of the war has supported this conclusion. A striking illustration is shown in the case of 10,000 Serbian prisoners who were subjected to famine, stress, and severe bodily diseases—e.g., typhus, typhoid, and tuberculosis—yet only five suffered with insanity. But not only are the psychoses (that is, insanity), but the neuroses are markedly hereditary, and as Dr. John Macpherson, the Scottish Commissioner in Lunacy, has pointed out, "the hereditary disease is transformable, neuroses appearing in the antecedents and collaterals of the subjects of the psychoses, and vice versa, from which we may imply a common hereditary basis." They constitute genetic variations from the normal, in respect of a hyper-excitability of the sensori-motor elements, owing to a narrow margin of the highest control of the brain, which renders the subjects susceptible to mental suggestion or to physical or mental impressions which do not similarly affect normally stable individuals. The symptoms usually commence to manifest themselves in early life, childhood, or adolescence. "The neuroses have no geographical or racial limit, but affect individuals of all human races, and, so far as that is possible, of several of the higher animal series."

ALCOHOL AND ITS INFLUENCE ON BODY AND MIND.

Alcohol, like syphilis, is a race poison, and affects every organ and tissue of the body. It is rapidly absorbed into the blood, and it passes from the blood into the fluid that surrounds and bathes the central nervous system; its first and immediate effect is as a narcotic upon the higher controlling centres of the brain; consequently, owing to its widespread abuse, it is the most important cause of disorders of conduct and crimes of violence, as prison statistics show. It is not so potent a cause of insanity as asylum statistics would seem to indicate. Why, then, is it assumed to be such a cause of increase of insanity? Firstly, because the data upon which the statistics are made are unreliable. Secondly, because potential lunatics, epileptics, and the feeble-minded have only a narrow margin of highest control, and a relatively small quantity is sufficient to make them antisocial, and thus reveal the unsound mind, so that they become certifiable. In support of this conclusion I would draw your attention to the following facts: I compared the results of 2000 post-mortem examinations, which I made at Claybury Asylum, with 2000 post mortems in Charing Cross and St. George's Hospitals, and whereas cirrhosis of the liver with dropsy very seldom occurred among the insane, it was a very frequent cause of death of the sane in hospitals. The inference is that the potential lunatic can seldom drink large quantities of alcohol for any length of time without his unsound mind becoming revealed. There is no doubt that persons who have suffered with head injury or brain disease are intolerant of alcohol. Alcohol and syphilis work together in undermining the constitution. Alcohol plays an important part in the spread of venereal disease. Many

¹ Those who are interested in this subject should read the philosophical work of Mr. Wilfrid Trotter, "The Herd Instinct in Peace and War."

a good man's life has been wrecked by loss of self-control on one occasion only—when he has indulged in excess of alcohol.

Control of the liquor traffic, especially of the sale of spirits, is necessary in the public interest, but I do not favour total prohibition. The sale of alcoholic beverages in the form of light beers and wines seems to be a reasonable mode of dealing with the question, and not likely to cause the widespread discontent that total prohibition would.

MENTAL HYGIENE AND THE TEACHING OF PSYCHOLOGICAL MEDICINE.

In America, for the past three years, there has been a very active development in the study of mental hygiene, and a quarterly journal dealing with the subject in all its aspects has been published by a National Committee of Mental Hygiene of which Mr. Clifford Beere is the secretary. He wrote a remarkable book entitled "A Mind that Found Itself." In this he gives his experiences of the treatment of his mind when it was unsound, and points out how illogical it had been. The objects of this national committee are to help both the physician and the patient; also to befriend the patient's relatives, to whom, when burdened with an actual or impending affliction, it would become an unfailing source of information, advice, or comfort. In a word, it would be a friend to humanity, and upon these lines this Committee of Mental Hygiene and its centres of activity have been doing most valuable work in the United States. It is such a "Before-Care Association" that we want in this country.

The war has shown the great need of systematic teaching of psychological medicine as a part of the medical curriculum. In 1907 (Vol. III., *Archives of Neurology and Psychiatry*) I strongly advocated this teaching for post-graduates, and suggested that a diploma of psychological medicine should be instituted, for I felt sure that it would raise the tone of medical men employed in the care of the insane and lead to diagnosis and better treatment of mental disease in the early curable stage. I also advocated the establishment of a psychiatric clinic in London, where the incipient and borderland cases could be seen and treated.

In a recent number of THE LANCET,¹ in an annotation on the Genesis of the Maudsley Hospital, the statement I made is quoted in full, and the article goes on to say that there is good reason to believe that it was this desire on my part to see a hospital in London for the study and treatment of neuroses and insanity in the early stages which induced Dr. Henry Maudsley to give £30,000 to the L.C.C. to build such a hospital. Unfortunately, this great physician, philosopher, and philanthropist died a few years ago, before the hospital, which is named after him, was fulfilling the objects which he contemplated. However, it did most valuable service during and after the war, and I hope that soon the Ministry of Pensions, who are at present using it, will be able to hand it over for civil use. I was convinced in 1907 that the institution of a diploma in psychological medicine would prove as valuable to that branch of medicine as the diploma of public health had been, and I called upon the President of the Royal College of Physicians to try and induce the Royal Colleges to give such a diploma, but I was quite unsuccessful. Just prior to the war the Cambridge University led the way and instituted such a diploma, and now many universities and the Royal Colleges give diplomas of psychological medicine. What is now required is the systematic teaching of the subject. For the past three months a course of psychological medicine, which will occupy six months, has been in operation at the Maudsley Hospital, under the direction of the L.C.C. The course has been designed for either the University, of Cambridge diploma or for that of the Royal Colleges. I am pleased to say that a class of 36 post-graduates have attended.

THE NEGLECT OF MEDICAL PSYCHOLOGY.

Sir George Newman, in his recent admirable report on Medical Education, states: It is deplorable that the English student of medicine should have no oppor-

tunity of learning modern methods of psychiatry or of diagnosing incipient and undeveloped cases of mental disease. And yet, in 1913, Parliament imposed statutory duties upon the medical practitioner, among them being: "He must be competent to diagnose all forms of mental disease" (Mental Deficiency Act, 1913). The public might ask, why did not the authorities previously insist upon proper training in this important branch of medical education, involving the liberty of the subject? The effects of this neglect of training in this important branch of medicine was shown in conscripting for the war. In the report of the Ministry of National Service physical fitness and unfitness only are considered.

It is difficult to understand, in the face of the report of Sir George Newman and war experience, that in the report of the Consultative Council on Medical and Allied Services, the scheme referring to the equipment of the Secondary Health Centres, Provision 57, does not include any department of neurology and psychiatry, although other and less important special departments of medicine are provided thus: skin, ear and throat, eyes, genito-urinary, dental, and industrial hygiene. Possibly, having regard to the fact that Dr. Addison, in a preface to my work on "Shell Shock and War Neuroses," fully recognises the importance of the subjects, the Ministry of Health may have in view some special scheme of dealing with neurology and psychiatry.

The importance of psychotherapy has been realised in the university of this great city, for courses of lectures have been given on this important subject by two leading authorities, Dr. Bernard Hart and Dr. W. McDougall. Academic psychology is not of practical importance to the medical man, although the knowledge of it is helpful; it is the study of conduct and its disorders considered biologically, as set forth by the late Dr. Mercier, which should engage his attention, and in conclusion I would remind my audience of the words of Francis Bacon, in his "De Augmentis," when he pleads for a study of mind and character: "That so we may have an accurate dissection of men's minds and characters, and the secret dispositions of particular men may be revealed, and that from a knowledge thereof better rules may be made for the treatment of the mind."

SOME ASPECTS OF FUNCTIONAL NERVOUS DISEASES.

BY E. D. MACNAMARA, M.A., M.D. CAMB., F.R.C.P.,
PHYSICIAN FOR MENTAL DISORDERS, CHARING CROSS HOSPITAL.

THE complicated, contradictory, and fluid views currently expressed as to functional nervous diseases, affections bordering upon definite mental disorder and established insanity, must prove exceedingly bewildering, not only to the practitioner of general medicine, but also to those who particularly devote themselves to neurology and psychiatry. In the study of the aetiology of such affections it was not so long since that endless time and tireless energy were devoted to the search for structural alterations of tissues examined post mortem and to the examination of the cytology and chemical composition of such fluids as are available for examination during life. Even now laborious works are being compiled and published full of descriptions of minute changes in the cells and in the chemical composition of fluids derived from cases of nervous and mental disease, but more striking, at least in bulk and novelty of content, is the gigantic output of literature of the last 20 years bearing upon psychology, normal and morbid, which contains little or no reference to anatomical findings and indeed not infrequently explicitly ignores them. The mind has come to be regarded as almost independent of the body, while the investigation of its processes is carried on solely in the psychological field. Many symptoms which not long ago were held to be due to faulty biochemical reactions are now ascribed to the ill-adaptation of mental processes.

¹ THE LANCET, March 13th, 1920, p. 618.

Anyone who has watched phases of the development of medical science and art will have been struck by the similarity of the genesis of fashions in therapy. A new idea is mooted and is almost at once carried to logical extremes by those who are of the imaginative and sanguine type of mind which especially loves "to tell or to hear some new thing." For instance, I remember when some years ago I set forth in a paper that a certain micro-organism had been discovered in a case of a certain disease, that I received the day after publication a wire asking for a curative serum for use in its treatment. On the other hand, we find a type of mind common and probably more widely diffused, though as a rule less voluble, which strongly and almost angrily resents the upset and readjustment of ideas involved in novelty. There is a third type, of which there are but few examples, in which criticism follows hard upon discovery, and in which ardour for the hypothetical is moderated by patience and cooled by experience. The protagonists clash in that which is obviously a welcome conflict and the din is deafening, while the small voice of genuine inquiry is only heard when they are exhausted by their vociferations or have found some new thing to interest them. In the field of functional nervous disorder we are still in the midst of the battle, but it may be worth while to attempt very briefly to set forth the position to which we have been carried.

Disease With or Without Structural Alteration.

By organic disease we mean that some alteration of structure has occurred, and that this alteration has been associated with a disturbance or cessation of function. There are also disorders in which structural alteration is not at all obvious, but of which physical agents are generally recognised as the cause, for instance, the affections which result from intoxication either by bacterial products or by poisons of other origin, from the effects of climate, or from those numerous circumstances which result in symptoms of exhaustion. In these affections in order to produce a cure it is generally enough to remove the causative agent. There remain, however, disorders of the various systems of the body in which structural alterations have not been decisively demonstrated, and about which the opinion is general that there may be none to demonstrate. In these disorders ætiological factors are obscure and do not appear to include physical agents among them, while physical agents used therapeutically appear to be of little or no value. The literature of the last century is strewn with the endeavours which were continuously being made to discover among physical agents the causes of functional nervous disease, and innumerable physical agents, including drugs, hydrotherapy, electrotherapy, rest, isolation, diet, climate, gymnastics, and metals were used in their treatment. So many and divergent have been these methods that some suspicion has been aroused as to the value of any of them. Confusion has also arisen from the fact that an agent apparently of value in some cases and in some hands has produced little or bad or no effect in other cases of a seemingly identical character. The problems which have thus arisen have of necessity turned men's minds in another direction, and it has been sought to discover whether mental processes might not, at least in some cases, eventuate in physical disorder, and whether many somatic symptoms might not be in fact the expression of disordered mental operations. These surmises were fortified by a consideration of the many therapeutic systems mostly extra-scientific and practised by those who were not trained as professional physicians. Miracles of undoubted authenticity and genuineness have been recorded from the earliest times, and though sometimes associated with physical agents have not been associated causally with them and have appeared for the most part to have been produced by the effect of the expression of the performer's mentality upon his patient. During the early part of the nineteenth century, owing to the work and reputation of Mesmer, the idea of the mind cure became extremely prominent, and various synonyms for mesmerism, such as hypnotism and suggestion, have marked attempts to raise the empiricism of Mesmer's pro-

cedures to a more scientific level. In the latter part of the last century arose the colossal movement known as Christian Science, the basic idea of which is the supremacy of the mind in its own and in the physical fields. In this case also the endeavour to raise empiricism to a scientific level has been an important stimulus of psychological research in the causation and cure of the somatic effects of psychic disturbance, and in the essential character of the disturbances themselves. Whether the causation of any affection be regarded as of physical or psychic origin, general principles of treatment still hold good—that is to say, the discovery, where possible, of the exciting cause and its removal, the neutralisation of its ill-effects, or where this is not possible, their palliation.

The therapeutic principle of palliation of symptoms of psychic origin is perhaps best exemplified by the method derived from the Stoics of inducing in the patient's mind a contempt of his bodily suffering, and a reliance on such fortitude as he can muster. The neutralisation of symptoms is exemplified by the method of suggestion under hypnosis in which injunction not to have certain symptoms sometimes results in their disappearance. The most truly radical mode of treatment, however, lies in the attempt to discover the mental irritant and to remove it. These modes of treatment have each of them ardent exponents, and any one of them would appear from current literature to be capable of the cure of all functional nervous diseases. In practice, however, these methods are discovered to be inextricably confused, to overlap and not by any means always to eventuate in the hoped-for results, while the time and labour involved both for patient and physician not infrequently render them impracticable.

Physico-genetic and Psycho-genetic Causes.

The causes of functional nervous disease may be divided into those which are physico-genetic and those which are psycho-genetic. Among the physico-genetic causes are the toxins of the bacterial infections and of intestinal stasis, the poisons manufactured in the body by faulty metabolism, as in gout and diabetes, poisons taken into the body, for instance, alcohol and morphia, and the excessive or defective amount of the secretion of the endocrine glands or its defective quality.

The psycho-genetic origin of certain functional nervous and mental disorders has been long and universally recognised. Before the physico-genetic causes were in the last century especially stressed, delirium, mania, melancholia, and delusions had been regarded sometimes as due to direct possession by the devil, and at others as the punishment of sin or the manifestation of a guilty conscience. The pendulum has again swung in this direction, though nomenclature has altered. Possession by the devil is not held to be a causative factor of functional nervous disease, but mental conflicts as the result of the opposition, on the one hand, of instinct, and on the other of education in its broadest sense is, in some quarters, held to be the basic and often the sole cause. It is a platitude to say that certain events make a more powerful impression than others, and that certain ages are more impressionable than others. Some events make such an impression that they are associated with the phenomena of physical "shock." Persons who have been shocked in this way often show symptoms which before the war were grouped under the heading of traumatic neurasthenia, and which during the war were given the euphemistic name of "shell shock." Other events do not produce shock but changes of a more subtle character, which may eventuate in states of mind which are not compatible with the instinctive and acquired mentality of the individual. Such states of mind may betray themselves in various ways as symptoms. In some such cases the origin of the symptoms may not be known by the patient, or a supposed origin may not be the true one. As a rough analogy derived from the somatic field may be mentioned the common experience that the dyspeptic often attributes his symptoms to heart disease, and is proportionately depressed by them, and that when their true origin is explained to him he sees how baseless and

unreasonable is the anxiety from which he had been suffering. In addition to the dramatic causation of cases of traumatic neurasthenia and shell shock, there are in all lives potentialities of worry—that is, of mental discomfort, distress, or even pain. Worry may be associated with the home, with the health and character and conduct of relations and friends, with their attitude towards the patient or with his towards them; with the patient's professional career, with the making of name and position; with society, its congeniality or uncongeniality, or with the level which it has assigned to the patient or with the level in to which the patient aspires; with religion, dissatisfaction with a faith and insufficient faith or scepticism, or the incompatibility of past or present conduct with some ideal standard; with politics and the incompatibility of things as they exist with the imagination of what they ought to be. Such factors as these are often very well known to the patient as sources of worry and as producing disharmony and conflict in his mind. Palliation, neutralisation, or complete abolition may be obtained by amended attitudes of mind and conduct. In some cases, however, the symptoms which take the patient to the physician are not recognised as the result of the worry, or, maybe, the mental disharmony or distress or conflict is not patent and explicit in his mind, and he is only brought to recognise it when the incongruities of his mentality are brought to light and become plain to him. Such an absence of clear recognition on the patient's part of his own mental disturbance may be of the nature of a defence against psychic discomfort or pain, and, in fact, due to the putting aside or repression of that of which the presence is not desired in consciousness. The process of repression appears to imply (1) an unpleasantness or a something to be repressed; (2) a tendency to forget the unpleasant, not necessarily consciously acknowledged, and which would, when it acts very early in life, seemingly amount to an instinctive process; (3) a power to put this tendency into operation and to make it effective; and lastly (4) that which may be called a mechanism of repression, the nature of which is not at present completely understood. That repression is not always absolutely complete is obvious, for if it were no past unpleasantness, whether remembered or not, would cause either mental distress or those symptoms which are alleged to be the expressions of unconscious conflict.

Mental Degeneration, General or Patchy.

In organic mental affections—e.g., general paralysis of the insane, chronic alcoholism, or arteriopathic dementia—there occurs a general all-round mental degeneration. In functional affections the symptoms are not those of an all-round degeneration, but are of a patchy distribution; for instance, there may be imperative ideas, obsessions, delusions, amnesia, morbid anxiety, phobia, anaesthesia, palsies, contractures, or such abnormal movements as tremors and tics. It would hardly seem worth while to explore the psychic aetiology of the symptoms of general paralysis, while it is as obvious that the exploration of the psychic factors of the aetiology of such symptoms as those just named must be very important. It should, however, always be remembered that various conditions of lowered physical health make symptoms of psychic origin more pronounced, and in many cases appear to be their direct excitant. This is also especially important in treatment, since the facilities at present obtaining in most neurological clinics as now conducted for prolonged mental examination are but small, and recourse has to be made to some of the crude though useful methods of physiotherapeutics. It is not proposed here to review such methods for the treatment of functional nervous disorders. Rest, isolation, electro-therapy, balneo-therapy, drugs, and careful dieting have their place as useful adjuvants of psycho-therapy in various cases, and as forming a scenic setting for its performance. With regard to modes of treatment whose object is to deal directly with morbid phenomena patently or not of purely mental origin, there are three which command the most attention—namely, suggestion, education or re-education, and analysis.

Three Modes of Treatment: (1) Suggestion.

A definition of suggestion has not been generally agreed upon. The term is used in many different senses. The primary meaning of suggestion is the putting forward of an idea with a view to its acceptance by the individual to whom it is proposed. Plainly the methods of proposition may be very varied, but perhaps it is correct to say that in medicine the term means the authoritative proposition of an idea for acceptance without question. Suggestions may be made when the patient is in a condition of artificial sleep or in the waking state. During hypnosis the patient's conscious mind is at rest and suggestions are made to the part of the mind which is not conscious. On the other hand, in the waking state suggestions are made to a part of the mind in which, as it is hoped, criticism is not aroused and in which there is a mental attitude of passive acceptance and obedience. Such appeals to the unconscious or to the unreflecting mind may undoubtedly, at least in some cases, mitigate or abolish symptoms. But it is obvious that in such a method the origin of the symptoms is not explored and their cause persists. There is probably a state of what may be called normal suggestibility, which is the usual one for most individuals, and it is to this normal state that political orators and newspaper editorials, directed towards the influencing of our "psychology," appeal. Most of our "opinions" are probably the result of various influences which have impinged upon us at impressionable periods of life and which are, in fact, founded upon but slight if any real ratiocination. There is also undoubtedly a condition of hyper-suggestibility in which some persons are prone to accept absurd propositions or those which are novel or extraordinary. When sick, or when they think they are sick, such persons try cure after cure simply because suggestion is made to them by advertisement or by enthusiastic friends that the various cures are infallible. It should here be remembered that an alternative name for hysteria is pithiatism, a word coined to express the opinion that hysteria is due to hyper-suggestibility. On the other hand, it is undoubtedly the case that some persons are hypo-suggestible. A few individuals are not prepared to accept propositions unless they are proven, an ideal state rarely, if ever, attained; while others have not reached this ostensibly high intellectual level, but are simply unreceptive of ideas to which they have not been accustomed or which they do not understand. Under treatment by suggestion may, perhaps, be placed a method which has come to be known as that of "shock tactics," in which a ferocious appearance, a hectoring manner, and a faradic current are combined to assure the patient that he has nothing really the matter with him. Suggestion under hypnosis is also used to induce the expression of a mass of pent-up emotion, the result of some direful experience. The memory of the experience has been repressed, with resulting symptoms of functional nervous disease. The patient is told under hypnosis again to live through the experience. He does so, and in so doing gives vent to the emotional expression proper to the experience. Such purgation of his unconscious mind may result in the disappearance of symptoms.

(2) Education.

In the therapeutic applications of education or re-education, in those cases where education has been defective or erroneous, appeal is not made to a mind which is not at the time conscious or under the spell of authority, habit, and custom, but is made to the developed and organised power of ratiocination. The appeal is generally by way of explanation and elucidation of symptoms, and an endeavour is made to arouse and develop firstly, a reasonable outlook, and secondly, the self-control which constitutes the normal repressing force. A method by which repression is effected and the power to repress doubtless exist and have been evolved because they have their value.

Just as the physical eye has, during evolution, learnt to see that which is useful for the purposes of the organism to which it belongs, and is neither microscopic nor telescopic in its powers, so has the psychic eye learnt to make its selections, while the rest is neglected as valueless or repressed for its unpleasantness. It is

not, then, unreasonable to suppose that there is in the individual a proper amount of the power of repression, and that in some this power is weak and results in hypo-repression, while in others it is strong and results in normal repression, or perhaps at times in over or hyper-repression. In hypo-repression that which it has been sought to repress may manifest itself in ways which are recognised by the patient as due to his defective power of repression or in ways which are not so recognised, and are expressed as symptoms of functional nervous disease. On the other hand, in hyper-repression in persons of considerable power of ratiocination and self-control, there may, for a time at least, be periods during which symptoms disappear or are tolerable, but there are likely to be other periods when their powers are weakened, perhaps owing to physical illness or to exhaustion, and when that which is repressed may again emerge and indicate its presence in morbid anxiety, in various symptoms of functional nervous disease, or in the tremendous spiritual conflicts of which accounts are frequent in "Lives of Saints." In this mode of treatment, as in treatment by suggestion, the origin of symptoms has not been investigated.

(3) Analysis.

In one aspect mental analysis is but an elaborated and systematised method of investigating the causes of functional nervous disease, but by its radical methods it also claims to remove the causes of disease and in this way especially to be of therapeutic value. The treatment of symptoms is held, as in general medicine, to be of less value than the discovery and eradication of the causes of disease. These causes are often of the nature of repressions, which occur in some cases so early that, as it has been observed, it is difficult to determine whether the process is an instinctive one or a result of early education. Repression certainly does occur later in life, when ideas which have been inculcated clash with instincts, or when one set of inculcated ideas clashes with another. In the latter case, at any rate, it is doubtful if it is necessary to carry an examination as far as infancy to discover the repressed idea. But in other cases it would appear that normal psychic growth has not been steadily progressive, and that in some respects it has become stationary, so that a conflict arises between this fixed set of ideas and other sets of ideas which have continued their normal progression.

Some of these fixations and repressions hinge upon the sexual impulse, but it is doubtful if in all cases it is necessary to insist upon such a connexion, at least if the word sexual is to be used in its customary sense. Recently the word has been given an extension which includes the "impulse towards life," relations between parents and children, and ordinary social relations between persons of the same or opposite sex. In the investigation of these relations it is somewhat difficult to avoid the feeling that too great a scope is occasionally allowed to the vagaries of the imagination, for they are extremely difficult to control in scientific investigation. In some cases, interpretations, seemingly wild, are confirmed, but occasionally also such interpretations appear to take the nature of a rather dangerous process of suggestion, the process being recognised neither by the patient nor the physician, and an imaginative interpretation is adopted by both and set forth as the cause of the disorder. Further, it is quite obvious to those having experience of cases which have been systematically investigated that the discovery ensuing from the investigation does not always eventuate in cure, or even alleviation. Failure to alleviate may be ascribed by the physician to his defective knowledge or faulty art, but when he comes across unrelieved cases which have been treated by the able, experienced, and learned, a similar doubt as to the correct nature of the technique cannot be raised, and he is obliged reluctantly to admit that this method, along with others at present in use, has its limitations.

From the practical point of view the time which a faithful analysis takes, owing to the numerous cross currents, false scents, and mare's-nests, often makes it impracticable as a form of treatment. Whatever the theory as to ætiology adopted, and whatever the mode

of treatment practised, it remains true that many, and perhaps the majority, of those suffering from functional nervous disorders get better, and, indeed, happily often lose their symptoms entirely. Many cases have also recovered without any pretence of treatment, or their cure has occurred during a treatment which has not perceptibly been causally connected with it. The repressive forces have perhaps become stronger, or the expanding or centrifugal force of that which is repressed has perhaps become weaker. Inquiry into the nature and strength of such forces is very much needed.

The fruits of experience and thought tend, above all things, to show that psychology is still in its infancy and that morbid psychology is younger still, that we cannot do much therapeutically, but that we can do something, and that we certainly cannot afford in examining a case to leave any stone unturned or in treatment to leave any method untried, whether it be derived from the physical or psychic worlds. To make too hard-and-fast a division between the psychic and the physical is to go unwarrantably beyond the data of experience. As physicians we have to deal with the mind and with the body, and where the sphere of the one begins and the other ends we certainly do not know, nor to what extent, for good or evil, they influence each other.

A CONTRIBUTION TO THE DIAGNOSIS OF ACTIVE PULMONARY TUBERCULOSIS.

By JOHN B. McDOUGALL, M.D. GLASG.,
M.R.C.P. EDIN., F.R.F.P.S. GLASG.,

CHIEF CLINICAL TUBERCULOSIS OFFICER, WEST RIDING OF YORKSHIRE.

At the recent Tuberculosis Conference in Leeds it was admitted by the pioneer of auto-inoculation therapy in England, Dr. M. Paterson, that "borderline" cases have been met with occasionally in his own practice. The excellent results at Frimley, however, can only be ascribed to the consummate care with which the patients were selected for graduated exercise, for certain it is that success depends very largely on prolonged rest, graduated if need be, coupled with close clinical observations, in all cases exhibiting signs of active disease in the chest.

This borderline type of patient may be described as follows:—

The temperature is normal when the patient is at rest in bed, and very frequently also on rising to have light exercise in the ward. The pulse-rate fluctuates between 80 and 90 per minute, and may not be more than 95 after dressing. Cough and sputum may or may not be present, and the physical signs in the chest may vary from an apical lesion of small dimensions to extensive disease involving both sides of the chest. The sputum, if present, may show no acid-fast bacilli, or these may be present in small or large numbers. If it be washed and plated, however, it will almost invariably be found to contain secondary invaders in varying numbers and kinds.

Pneumococci and streptococci are common, but staphylococci, *Micrococcus catarrhalis*, and other organisms are frequently observed. The patient himself has a feeling of comparative well-being, and may complain of nothing except the ennui of restricted freedom. He is apparently fit and well enough to take a step forward in treatment. The first step may be a successful one, but more frequently it is followed by a rise in temperature, accompanied by the symptoms of uncontrolled auto-inoculation. Much, if not most, of the damage caused by indiscriminate tuberculin therapy has been in this type of case.

Leucocyte Counts giving Quantitative and Qualitative Cell Picture.

With a view to establishing an objective proof of latent activity in this "borderland" type the author has carried out a large number of blood examinations, the details of which have been published elsewhere. I have found this helpful in guiding to a definite conclusion, one way or another, as to the suitability of a particular case for treatment by graduated rest and exercise.

The method is as follows:—

Total white cell counts are made at intervals during the day; blood examinations during the night are not necessary.

For practical purposes counts every three hours are sufficient. A note should be made of the temperature and pulse-rate on each occasion a total white cell count is made. The process should be repeated the following day if possible, and again at later dates until a definite conclusion is arrived at. Blood films are also taken at weekly intervals, the time, date, temperature, and pulse-rate being noted at the same time. A differential white cell count should be made, and finally an Arneth count of the nuclei of the polymorphonuclear leucocytes. A white cell picture is thus obtained. It is quantitative as well as qualitative.

From an analysis of 67 cases in which 150 differential counts of the white cells, together with Arneth counts, were made, and of 30 cases in which 250 total counts were estimated, the following conclusions were reached:—

1. If consecutive daily leucocyte counts are made, a variation in total numbers of white cells is found in all active cases of pulmonary tuberculosis—a variation in excess of that occurring normally in health. (See Leucocyte record A.)

2. Physical signs in the chest may give little or no help in determining the activity of a lesion. For instance, a cavity in the lung may be followed by pathological "repair" and clinical quiescence, and in such a case the total leucocyte count may be small, and the Arneth count but slightly altered. (See B.) Conversely, there may be a definite "leucocyte swing", and a marked "deviation to the left" in cases showing no other objective sign of active disease.

3. The total leucocyte count bears a definite relationship to the acuteness of the lesion in the chest, and the acuteness of the lesion has, in turn, a more or less intimate connexion with the presence of organisms other than the tubercle bacillus.

4. The Arneth "deviation to the left" (a phrase synonymous with an increase in cells of Class I. and II.—i.e., those with one or two nuclear segments) is established in all cases of active disease. The more severe the infection the greater is the deviation to the left. (See C.)

5. An approximation of the quantitative and qualitative blood picture to the normal is a favourable sign and indicates quiescence.

Significance of Total White Cell Count and its Fluctuations.

Examinations of the sputum and cultures from the lung tissue in all cases of advanced tuberculosis prove that organisms other than the tubercle bacillus play an important part in the bacteriology of the disease. (Ortner,¹ Petroff,² Ravenel and Irwin,³ and others.) We know that, unlike the pneumococcus,⁴ the toxins of the tubercle bacillus do not stimulate the production of polymorphonuclear cells. It is the rule to find leucopenia with relative lymphocytosis in early and also in advanced but quiescent cases of phthisis. Further clinical proof of the fact that the tubercle toxins do not encourage leucocytosis may be cited from the blood investigations in cases of miliary tuberculosis, where massive doses of tubercle toxin are constantly in the circulation. (See D, from Cabot.) All authorities agree that leucopenia is the rule in these cases. From two cases seen I am in a position to verify this statement. Treadgold's animal experiments are significant.⁵

It would appear, therefore, that the leucocytosis found in cases of active pulmonary tuberculosis is an indication of the "septic" element in the pathology of the disease, and it may be deduced that these "secondary" invaders give rise to hæmatological changes in the absence of other clinical signs of active disease in the lung.

To explain the low counts which interpolate themselves with such regularity and frequency in certain cases of pulmonary tuberculosis is difficult. They are not due to rest, nor can bone-marrow exhaustion explain them. Bone-marrow exhaustion, however, is not to be diagnosed from estimations of the total leucocyte count alone. The qualitative picture must also be considered. An apparently satisfactory quantitative reaction may be in reality a bad qualitative one, indicating failure of the bone-marrow. A third possible explanation of the "leucocyte swing" is that it is due to periodical intermissions from the diseased focus of substances acting on the polymorphonuclear cells by negative chemiotaxis.^{6, 7} The balance between the various toxins can never be equal, and in this way the leucocyte swing is maintained, being elevated when the "pyogenic" toxins are in excess, and being low when the blood stream is surcharged with tubercle toxin.

Significance of "Deviation to the Left" (Arneth).

The precise significance of the "deviation to the left" in the presence of an infection is problematical. This was dealt with in a note on "The Neutrophile Index" in THE LANCET of April 24th, 1920. I regard the excess of cells with one or two-lobed nuclei as due to an increased and excessive demand on the activities of the bone marrow. It is unfair to assume that the bone marrow can keep up a satisfactory response in quantity and quality over a long period of time, as in mixed pulmonary infection. Quality suffers before quantity, if we are to take the Arneth deviation to the left as a criterion of cellular efficiency; and from the large mass of work which has been done on the Arneth count, we are entitled to believe that the cells in Classes I. and II. are indicative of an ebbing immunity when they are in excess.

In the presence of a large number of "single-lobed" polymorphs such as is found in acute infection it is matter for surprise that myelocytes are not found much more frequently. Cells described as myelocytes have been found by Wack and Kast,⁸ working independently. Personally I have never been able to identify true myelocytes in any of the films I have examined, not even in cases where the index has been over 95. It may be said, I think, that the deviation to the left is an expression of qualitative bone-marrow exhaustion, as distinct from quantitative. In miliary tuberculosis it has been shown that a leucocytosis is not a feature of the disease, and yet the Arneth count exhibits a deviation to the left as in most intoxications. (See E.) So also in intestinal diseases in children, it has been pointed out by Esser⁹ that a similar phenomenon may be observed. I know of no observations which have been made on the neutrophile index in patients suffering from syphilis, whooping-cough, or typhoid fever, but until further observations are forthcoming in these diseases it can be suggested tentatively that aggressins, or the toxins associated with organisms which do not cause leucoplasic reaction, act on the bone marrow by inhibiting the development of the young polymorphic cell.

Some Illustrative Leucocyte Records.

A. On admission patient was pale and very much emaciated. At first the temperature was very unsteady, running between 98° and 100° F. The pulse-rate did not come below 90 per minute, despite evening temperature on Jan. 24th being normal. Several examinations of the sputum were made; on each occasion tubercle bacilli

FIG. 1.—Leucocyte counts were made on Dec. 17th at 2, 3, 4, 5, 7, 8, 10, and 11 P.M.; on Dec. 18th at 4, 10, 11 A.M. and 2 P.M.; on Feb. 22nd at 8 A.M., noon, 1, 2, 4, 5, 6, 7, and 11 P.M.

were found. The physical signs in the chest showed impairment of resonance over right upper lobe with harsh breath sounds and numerous crepitations over the same area. On Feb. 29th the case closed dramatically. Hemoptysis was so profuse that patient died five minutes after onset of bleeding. (Fig. 1.)

B. Patient was extremely emaciated. T. 99.4°–100.4° F. The sputum contained tubercle bacilli in large numbers—50 to 60 to the field.

H Z

Both sides of the chest, back and front, were dull to percussion. On auscultation, the respiratory murmur was very harsh over the entire chest, especially on left side, where whispering pectoriloquy could be heard. There were other definite signs of cavity formation over the upper lobe on left side. Numerous moist sounds accompanied both inspiration and expiration in both upper lobes. Arneth index, 71.5. (Fig. 2.)

C. Male, aged 24. Onset three months previous to date of first blood examination. Family history bad. General condition poor. Temperature 99° to 102° F. Pulse 100 to 110 per minute. Signs of acute disease in left lung and in upper lobe of right lung. Sputum contained tubercle bacilli, streptococci, staphylococci, and numerous diplococci. Patient died Dec. 24th.

BILHARZIA TREATED WITH TARTAR EMETIC.

By F. G. CAWSTON, M.D. CANTAB.

THE study of a number of bilharzia patients who have undergone a course of treatment by intravenous injections of tartar emetic would appear to show that the best results are obtained where the injections are given on alternate days for most of the time, and the treatment is continued for a complete month. It has been my practice to commence with gr. $\frac{1}{2}$, and in only one case of idiosyncrasy have I noticed any severe effect from this initial dose. On that occasion the patient of 15 experienced great abdominal pain, vomiting, and collapse about four hours after the administration of the drug; this condition lasted till midnight. The second day I give half a grain, and on the third three-quarters. I then give, on alternate days, from one to one-and-a-half grains, and continue the injections for three to five weeks, according to the disappearance of ova from the urine. If the solution is absolutely fresh and the injections are given regularly, a total of from 12 to 15 gr. would seem to be sufficient to effect a permanent cure in the majority of cases.

Toxic effects are less common in patients who are given a solution of the drug which has not been freshly prepared, and it is reasonable to suppose that the drug loses much of its effectiveness if the solution is allowed to stand for even a short while after it has been made and boiled. There is also the danger of fungus-growth in solutions of tartar emetic. This presents the appearance of small flakes of cotton-wool, and is noticeable after the solution has been standing for only a few hours. The risk of injecting even small quantities of this into the general circulation can be avoided by dissolving the powdered tartar emetic by boiling in

FIG. 2.—Leucocyte counts were made at 10 A.M., noon, 2, 4, 5, 7, 8, and 11 P.M.

distilled water and injecting it before it has become cold. I find a solution of gr. 4 in 16 c.cm. of distilled water is a suitable preparation to give in all cases that have come under my care. This renders an ordinary hypodermic syringe a convenient one to use for the smaller doses.

There is an accumulative effect of tartar emetic which was well shown in a patient of mine whose skin under a wrist-watch was markedly blackened after receiving a total of 12 gr. of the drug. By giving the injections on alternate days we make good use of this accumulative action and make smaller doses more effective. As a rule, daily injections should be avoided, for the patient should be given time to recover from all toxic effects of the drug before receiving further injections. Toxic effects are undoubtedly lessened where the injections are given shortly after a light breakfast, instead of later on in the day. This point has been emphasised by Dr. J. B. Christopherson,¹ and is borne out by my own experience.

In the series of cases given in Table I. a comparatively small total dosage has proved sufficient, for in every instance the ova degenerated gradually until they disappeared completely, and the urine has remained free from blood for periods of from two to six months.

TABLE I.

—	Age.	Duration of disease.	Urine: emetic injected + many.	Grs. of tartar emetic injected in No. of days.	Result in No. of days after injection.
C. C.	20	1 week.	+	5 $\frac{1}{2}$ (15)	No ova (145)
C. W.	12	1 $\frac{1}{2}$ yrs.	++	13 $\frac{1}{2}$ (34)	" (36)
H. R.	9	2 "	++	6 $\frac{1}{2}$ (35)	" (120)
W. M.	29	7 "	++	12 $\frac{1}{2}$ (25)	" (47)
O. S.	19	7 "	+	14 (30)	" (86)
A. S.	39	25 "	+	11 (20)	" (127)
H. B.	12	4 "	++	8 $\frac{1}{2}$ (34)	" (198)
J. B.	10	4 "	++	8 $\frac{1}{2}$ (35)	" (198)
D. C.	15	5 "	++	12 $\frac{1}{2}$ (27)	" (82)
L. D.	21	1 "	+	9 $\frac{1}{2}$ (21)	" (41)
J. W.	16	3 "	+	11 $\frac{1}{2}$ (27)	" (169)
S. C.*	28	15 "	+	10 $\frac{1}{2}$ (21)	Negative blood test (28)
C. R.	13	2 "	++	9 $\frac{1}{2}$ (35)	No ova (37)
					1 dead ovum (110)

* With positive blood test.

In the series of cases given in Table II. where the attendance of the patients was irregular or the course of injections stopped early for one cause or another, degenerated ova were found in the specimens of urine examined some weeks after the injections ceased.

TABLE II.

—	Age.	Duration of disease in years.	Ova in urine.	Grs. of tartar emetic injected in No. of days.	Remarks.
E. T.	16	5 $\frac{1}{2}$	++	13 $\frac{1}{2}$ (25)	Hæmaturia after 108 days. (Ova all apparently dead.)
H. W.	24	5 $\frac{1}{2}$	++	12 $\frac{1}{2}$ (24)	Two ova, one alive after 92 days.
J. C.	21	1 $\frac{1}{2}$	++	10 $\frac{1}{2}$ (21)	Hæmaturia after 177 days.
F. G.	16	4	++	11 (38)*	Many ova after 76 days. (Degenerated.)
B. T.	17	7	++	12 $\frac{1}{2}$ (25)†	Living ova after 62 days.
F. McN.	15	5	+	12 $\frac{1}{2}$ (32)†	Living ova after 73 days.

* Missed three days running. † Missed four days.

Two apparently dead ova were found in another patient's urine 277 days after treatment had ceased. He had received a total of 12 $\frac{1}{2}$ gr. in 40 days, besides some intramuscular injections of colloidal antimony. As he had suffered from hæmaturia daily for the previous 18 years and had seen no suggestion of it since his treatment, it is reasonable to suppose that he is cured of the disease. Another, whose treatment was discontinued at the end of only a fortnight on account of a severe "cold" following an injection in January last, reported a recurrence of his symptoms three months later. He had received a total of under 9 gr. of tartar emetic, and a full course of 15 gr. was given to make his cure complete.

THE BLOOD AND URINE IN PANCREATIC DISEASE.

BY P. J. CAMMIDGE, M.D. LOND.,
J. A. CAIRNS FORSYTH, F.R.C.S. ENG.,
AND
H. A. H. HOWARD, B.SC. LOND.

I.

IT was shown by one of us in 1904¹ that when the urine of a patient suffering from an inflammatory affection of the pancreas is boiled with hydrochloric acid, the excess of acid neutralised, and a phenylhydrazin test carried out with the resulting liquid, a much larger yield of osazone crystals is obtained than with a normal urine treated in a similar manner. Later the test was modified, and its delicacy increased, by removing glycuronic acid from the boiled urine with subacetate of lead before heating with phenylhydrazin.² Subsequent experiments with dogs, conducted in conjunction with Mr. H. C. G. Semon, confirmed the results of clinical experience, and showed that an increased formation of osazone crystals after hydrolysis of the urine occurs when the functional activity of the pancreas is interfered with by operation.³ An investigation of the crystals carried out at the same time proved that they had the characters of a pentosazone. In order to eliminate the personal factor as much as possible from the test and secure figures by which one case might be compared with another, and with the normal, a quantitative method was devised and described in 1913 under the name of the "Iodine Coefficient of the Urine."⁴ This method had the advantage of being applicable to diabetic as well as to sugar-free urines, so that it was possible to investigate the functional activity of the pancreas in cases of glycosuria. A long series of observations showed that the iodine coefficient of healthy urine is nil, but that in cases of pancreatic disease it varies from 12 to 20 per cent., with a total of 100-200 units for the 24 hours. Meanwhile the nature of the pentose formed on hydrolysing pancreatic urines with an acid, and the composition of the mother substance from which it was derived, were being investigated, and in 1914 it was proved that the pentose has the characters of xylose and that the mother substance corresponds in chemical properties and composition to a dextrin.⁵ Further research was interrupted by the war, but during the past year it has been resumed with results which we propose to discuss in this and subsequent papers. We shall there describe the investigations we have made into the origin of the urinary dextrin, and consider a series of new observations we were led to carry out on normal carbohydrate metabolism, and the changes occurring in diabetes mellitus, which we believe throw considerable light on the aetiology of that condition and furnish a basis for a more scientific treatment than has been possible hitherto.

The "Difference Value" of the Urine in Pancreatic Disease.

Before dealing with these subjects it will be convenient to refer to a comparatively simple process for estimating the dextrin content of the urine in cases of suspected pancreatic disease, which we have employed for some years in place of the so-called pancreatic reaction. It takes much less time to carry out than the iodine coefficient and, although not quite as accurate, gives comparable results, 3 units by the new method corresponding to 1 unit of the iodine coefficient; thus in cases of pancreatitis readings of 20 to 60 units per cent., with a total of 100 to 500 units for the 24 hours, are usually obtained. This method cannot be applied

satisfactorily to urines containing more than a trace of sugar, and for such the more laborious iodine coefficient must be employed. A specimen of the urine is boiled with hydrochloric acid and, after the excess of acid has been neutralised, it is made faintly acid and liberated glycuronic acid removed by treatment with subacetate of lead. The fluid is then made up to a definite volume with water and filtered. The reducing power of an aliquot part of the clear filtrate is now determined by some delicate and accurate process, such as that described by one of us in 1917.⁶ The reducing power of the filtrate from a sample of the unboiled urine, made faintly acid if necessary, treated with subacetate of lead, and diluted to a like degree, is also ascertained by the same method. The difference between the results, which we term the "difference value" of the urine, is a measure of the dextrin present. The details of the process are as follows:—

20 c.cm. of the urine are placed in a small flask and 2 c.cm. of hydrochloric acid (sp. gr. 1.165) are added. The neck of the flask is closed with a small funnel to act as a condenser, and the contents are boiled on a sand-bath for exactly 10 minutes. The excess of acid is then neutralised by adding 5 c.cm. of a saturated solution of sodium carbonate, slowly and with constant shaking, until frothing ceases. A dilute solution of acetic acid is now added drop by drop until there is no more effervescence and the fluid is faintly acid in reaction. The contents of the flask are transferred to a 50 c.cm. volumetric flask (A) and the flask in which the boiling has been carried out is washed out with a little water, the washings being added to the contents of the volumetric flask. The fluid is now well shaken with about 5 g. of subacetate of lead, made up to 50 c.cm. with water, mixed, and filtered. A control is prepared by mixing in a second volumetric flask (B) of the same capacity 20 c.cm. of unboiled urine, made faintly acid if necessary with a few drops of dilute acetic acid and about 5 g. of subacetate of lead. After being thoroughly shaken this is diluted to 50 c.cm. with water, mixed, and filtered. The reducing power of the hydrolysed (A) and the unhydrolysed (B) urine may be compared as follows: 3 c.cm. of a modified Benedict solution⁷ and 1 c.cm. of a saturated solution of sodium carbonate are placed in each of two small flasks, provided with funnels in their necks to act as condensers, brought to the boil on a wire gauze and boiled for a few seconds to expel dissolved oxygen. Exactly 5 c.cm. of the filtrate from the flask A is added to one, and the same amount of the filtrate from flask B to the other. The boiling is then continued for exactly three minutes. At the end of that time 3 c.cm. of hydrochloric acid (sp. gr. 1.165) are cautiously run into each flask from a pipette, and the contents of the flasks are quickly poured into two larger flasks containing 100 c.cm. of previously boiled and cooled water, and 20 c.cm. of N/100 iodine solution, through thistle funnels drawn to jets which project below the surface of the iodine mixture. After washing out the boiling flasks with a few cubic centimetres of hot water, and adding the washings to the iodine solution, the larger flasks are thoroughly cooled and the excess of iodine in each is titrated with N/100 sodium thiosulphate solution, using a few drops of fresh starch solution as the indicator. The difference between the amounts of thiosulphate solution required to discharge the blue colour from the contents of the flasks, expressed in cubic centimetres and multiplied by 50, gives the percentage "difference value" of the urine.

The Difference Value of the Blood.

In attempting to trace out the source of the urinary dextrin in diseases of the pancreas attention was first turned to the blood. As it was obviously impossible to obtain sufficient material clinically from the peripheral circulation to isolate, or directly determine, a substance like dextrin, which has no very characteristic chemical properties, and would only be present in small quantities, a procedure similar to that employed for estimating the difference value of the urine was adopted. In our earlier experiments the reducing power of a protein-free filtrate from the blood before and after hydrolysis with hydrochloric acid was estimated by the method described by one of us in THE LANCET in 1917 and 1919, but later a modification of the Folin and Wu

⁷ Dissolve 100 g. of anhydrous, or 200 g. of crystallised, sodium carbonate, 200 g. of sodium citrate, and 10 g. of sodium bicarbonate in about 600 c.cm. of distilled water by the aid of heat and add to it, with constant stirring, a solution consisting of 21 g. of crystallised copper sulphate dissolved in about 150 c.cm. of water. When the mixture has cooled to the room temperature make up to 1000 c.cm. with distilled water and filter.⁶

process⁸ was adopted as a routine procedure, since it effected a considerable saving of time when a large number of analyses were being made, as was necessary in this series of investigations, in the course of which we have examined some 3000 specimens of blood. Experiment showed that the results were the same with both methods within the limit of experimental error, which proved to be about 0.002 per cent. in either direction in experienced hands. We found that the smallest amount of blood with which we could work satisfactorily was 0.3 c.cm., and this is the quantity we have usually employed in our work on the human subject, obtaining it from the root of the nail after constricting the finger by swinging and constricting it with a narrow rubber band.

The required quantity of blood (0.3 c.cm.) is measured in an accurately graduated narrow pipette and delivered into 4.5 c.cm. of water contained in a test-tube of hard glass. The contents of the tube are thoroughly mixed and allowed to stand for a few minutes; then 0.6 c.cm. of sodium tungstate solution (half the strength described by Folin and Wu⁹) and the same amount of 1/3 N. sulphuric acid, measured with a clean pipette, are added and the contents of the tube well mixed. It is now heated in a bath of boiling water for a few minutes to ensure complete coagulation of the protein, cooled, and the contents filtered. Two narrow test-tubes marked with a 12.5 c.cm. mark are next taken, and into one of them is introduced exactly 2 c.cm. of the clear filtrate and into the other 1 c.cm. of a 0.01 per cent. solution of pure dextrose

FIG. 1.—Normal blood taken at hourly intervals after a test-breakfast. S, Sugar per cent. $\times 1000$; D, Difference value per cent. $\times 1000$; A, Amylolytic ferment per cent. $\times 10$; F, Fasting values. B, Breakfast.

and 1 c.cm. of distilled water to act as a standard. To each is added 1 c.cm. of Folin and Wu's alkaline copper solution, and the tubes are heated in a boiling water-bath for exactly six minutes. At the end of that time, without cooling, 0.5 c.cm. of an acid mixture containing sodium molybdate and sodium tungstate ("phenol reagent") is added to each. The tubes are gently shaken to dissolve the precipitate, cooled in running water, and 2.5 c.cm. of a saturated solution of sodium carbonate introduced. They are then made up to the 12.5 c.cm. mark with water and allowed to stand for 5 minutes. The depth of colour of the liquid in the tubes is then compared in a colorimeter, and from the results obtained the percentage of sugar in the blood is worked out. To obtain the hydrolysis value of the protein-free blood 2 c.cm. of the original filtrate are placed in a narrow test-tube with a 12.5 c.cm. mark and mixed with 0.5 c.cm. of hydrochloric acid, 2.5 per cent. The mixture is heated in a boiling water-bath for an hour, then cooled and neutralised by adding a saturated solution of sodium carbonate until effervescence ceases and the reaction of the liquid is faintly alkaline to litmus. The fluid is then treated in exactly the same way as described above for the estimation of the simple sugar. The hydrolysis sugar value given by the last estimation, less the value for the simple sugar obtained in the first determination, represents the "difference value" of the blood.

Observations on normal blood have shown that the difference value has a very limited range, varying from 0.002 to 0.008 per cent., and that it is not appreciably influenced by food or the nature of the diet. When examinations are made at hourly intervals after a meal a slight fall from the fasting level is usually seen at the end of the first and second hours, but by the third or fourth hour the value is again the same as when fasting or very little higher. In any case, the variation is so slight, not exceeding 0.006 per cent., as to be almost within the limit of experimental error, but the constancy of the change in a large number of observations is against this being the entire explanation. (Fig. 1.)

On carrying out a series of similar hourly examinations with blood from a case of pancreatic disease very different results are obtained. The fasting level is always considerably higher than normal, ranging from 0.050 to 0.150 per cent. in the cases coming under our observation. After a meal a rapid fall occurs for the first three hours, when, if no more food is taken, a return to the fasting level gradually follows, so that in six or seven hours the cycle is completed. On comparing the percentage of sugar in the blood with the difference value a striking relation is seen, for as the difference value falls after a meal the sugar rises to the maximum of the latter corresponding to the minimum of the former, and with the succeeding rise in the difference value the percentage of sugar drops until the fasting relation is again reached. Thus, when the respective values are plotted out in a graph the sugar curve and the difference value curve move in opposite directions.

FIG. 2.—Blood from a case of chronic pancreatitis, with a gastric ulcer invading the pancreas, taken at hourly intervals after a test-breakfast. S, Sugar per cent. $\times 1000$; D, Difference value per cent. $\times 1000$; A, Amylolytic ferment per cent. $\times 10$; F, Fasting values; B, Breakfast.

FIG. 3.—Daily readings of blood and urine from a case of chronic pancreatitis. S, Sugar per cent. $\times 1000$; D, Difference value of blood per cent. $\times 1000$; I, Iodine coefficient of urine per cent. $\times 10$; T, Total iodine coefficient of urine per 24 hours $\times 10$.

(Fig. 2.) This relationship appears to be characteristic of a disturbance of the functions of the pancreas. The nature of the food taken seems to exert very little influence on the difference value curve or its relation to the sugar curve, a mixed diet, a meat meal, or a carbohydrate meal all giving very similar results. The only exception we have found is when the food consists entirely, or largely, of dextrinised starch, and in this case the difference value falls rather more slowly, and does not reach quite as low a level as when a mixed feed or an ordinary carbohydrate meal has been taken, suggesting that the difference value of the blood is then dependent to some extent upon the presence in the peripheral circulation of dextrins absorbed from the alimentary tract. But the fact that a protein-fat meal gives practically the same results as a meal of ordinary starchy foods is against the direct absorption of dextrins from the intestine being the usual explanation of the difference value of the blood.

It has been known for a considerable time that normal blood contains small quantities of a carbohydrate substance which yields a reducing body on boiling with a dilute acid. Freund obtained 0.82 g. of such a substance from 4 litres of ox blood, corresponding

⁸ Practitioner, civ., 2, February, 1920, p. 114.
⁹ Jour. Biol. Chem., xxxviii., 1, 1919, p. 81.

to 0.02 per cent. in 1892,¹⁰ but no attempt appears to have been made, then or since, to investigate its source or significance, and with the exception of a few observations made by Lépine and Boulud in 1907,¹¹ the effects of disease, and particularly the influence of defective carbohydrate metabolism, on the amount present in the circulation do not seem to have been studied. Lépine and Boulud found that when the blood of a healthy dog was boiled with hydrofluoric acid its reducing power was increased by about 0.77 per cent., and that when the blood of a depancreatized animal was similarly treated a much larger increase occurred, a difference of 1.27 per cent, being met with in one instance. They accounted for the increase on hydrolysis by assuming the presence of a "sucre virtuel," but as they used whole blood for their experiments a considerable proportion of the "sucre virtuel" was no doubt reducing substances split off from the proteins of the blood by the action of the acid. Our experiments have been carried out with the protein-free filtrate, and the figures obtained represent therefore only the reducing power of the hydrolysable carbohydrate present in the peripheral circulation and are consequently much lower than those quoted by Lépine and Boulud. Our values for normal blood correspond more closely to the percentage for ox blood found by Freund than those given by the French observers, and tend to confirm the conclusion that a hydrolysable carbohydrate is a constant constituent of the blood. The fact that the percentage is enormously increased when the functional activity of the pancreas is interfered with by disease points to the amount of this substance in the circulation being controlled by some influence exerted by the gland on carbohydrate metabolism.

The Difference Value of the Blood and the Dextrin Content of the Urine.

In our earlier attempts to establish a relationship between the difference value of the blood and the dextrin content of the urine, as indicated by the iodine coefficient, we determined the former at a fixed time, usually three hours after breakfast, and compared it with the iodine coefficient of the collected 24 hours' urine for a number of consecutive days. Although the results when plotted out in a graph gave curves which were on the whole of a similar type (Fig. 3), the agreement was not sufficiently constant to warrant the inference that the one was related directly to the other, uninfluenced by any other factor. Later, when we had discovered the effects of the ingestion of food on the difference value of the blood, one reason for the occasional divergence of the curves became clear, and we therefore proceeded to compare the iodine values of the urine collected at hourly intervals, before and after a meal, with the difference values of samples of blood taken at similar intervals. On plotting out these results they were found to correspond very closely, suggesting that the dextrinuria of pancreatic disease is directly dependent upon the presence in the blood of a substance or substances, yielding a reducing body on hydrolysis with an acid, and therefore probably of similar composition. (Figs. 4 and 5.)

The Amylolytic Ferment of the Blood and Urine in Pancreatic Diseases.

Having found that the iodine coefficient of the urine is directly related to the difference value of the blood and that there is probably, therefore, an abnormal dextrin content in the blood in pancreatic disease, the next step was to determine the source of this dextrin. As dextrans are intermediate bodies formed during the conversion of starch, or glycogen, into sugar the most likely source of the dextrin was either absorbed products of digestion from the alimentary tract or converted glycogen, from the glycogen reservoirs of the body, which, owing to inefficient action of the pancreas, was not completely broken down to sugar, but passed into the blood stream at the soluble dextrin stage. As we have already seen, it is not likely that the difference

value of the blood is directly dependent upon material coming from the alimentary tract, for, both normally and in pancreatic disease, its value is largely independent of the nature of the food; moreover, the fact that the difference value of the blood and the iodine coefficient of the urine are highest in the fasting state is strong evidence against such a conclusion. The glycogen stores of the body, and particularly the liver, seemed, therefore, to be the most likely source. It is well known

FIG. 4.—Blood from a case of cirrhosis of the pancreas, with defective fat digestion and intermittent glycosuria, taken at hourly intervals after a test-breakfast. S, Sugar per cent. $\times 1000$; D, Difference value per cent. $\times 1000$; A, Amylyolytic ferment per cent. $\times 10$; F, Fasting values; B, Breakfast.

FIG. 5.—Urine from the same case as Fig. 4, taken at hourly intervals. T, Total iodine coefficient per hour $\times 10$; A, Amylyolytic ferment per hour $\times 10$; S, Sugar per hour $\times 10$; F, Fasting values; B, Breakfast.

that the amylolytic ferment of the urine is increased in diseases of the pancreas, and it occurred to us that if we could correlate the ferment contents of the blood and urine, with the difference value of the blood, and the iodine coefficient of the urine, it would tend to confirm the diagnostic value of the methods of examination we have described and probably give information bearing on the point in question.

For the estimation of the amylolytic ferment in the urine we employed the Wohlgemuth process, and for the blood devised the following method:—

0.2 c.cm. of blood is delivered into 2 c.cm. of water and thoroughly mixed. The protein is then precipitated by adding 0.4 c.cm. of Folin and Wu's sodium tungstate solution (half strength), and 0.4 c.cm. of N/3 sulphuric acid. The mixture is gently shaken, and without being heated is filtered. 1 c.cm. of the clear filtrate is then measured into each of two narrow test-tubes marked with a 12.5 c.cm. mark, containing 1 c.cm. of a 1/100 starch solution. One of the tubes is heated in a boiling-water bath for a few minutes to destroy the ferment and act as a control, and is then cooled. Both tubes are now placed in the incubator at 37°C., and left undisturbed for one hour. At the end of that time the sugar in each is estimated by the modified Folin and Wu process previously referred to in connexion with the determination of the difference value of the blood. The difference in the results, expressed in milligrammes of sugar, multiplied by 15, is taken as the amylolytic ferment index of the blood. If possible it is preferable to use a larger amount of blood for the estimation (e.g., 1 c.cm.), but with care satisfactory results may be obtained with the quantity mentioned. Experiment has shown that when 1 c.cm. of blood is employed the milligrammes of sugar, or when 0.2 c.cm. of blood is used the milligrammes multiplied by 15, correspond to units on the Wohlgemuth scale for urine.

With this method the amylolytic ferment of normal blood ranges between 2 and 5 units per cent., the lower figure being found in the fasting condition and the higher two or three hours after a meal. Simultaneous estimations of the amylolytic ferment and sugar in normal blood after feeding give curves of similar amplitude. (Fig. 1.) On examining the blood and urine from cases of pancreatic disease at hourly intervals it

¹⁰ Centralbl. f. Physiol., 1892, vi., S. 345.

¹¹ Lépine: "Le Diabète Sucré," Paris, 1909, pp. 65, 345.

was found that the amylolytic ferment content of the two corresponded, and that when plotted out in a graph their curves moved with the percentage of sugar in the blood (Figs. 4 and 5) as in health, but at a much higher level. The difference value curve of the blood and the iodine coefficient curve of the urine, on the other hand, pursue an opposite course, the highest readings being obtained when the ferment and sugar are lowest, and vice versa. It would therefore appear that as the amylolytic ferment of the blood increases during digestion the sugar rises to a corresponding degree, but that the abnormal formation of dextrin-like bodies characteristic of the fasting state in disease of the pancreas is gradually checked. These results suggest that sugar and the substance on which the difference value of the blood depends have a common origin, and that the proportion between them varies with the amount of amylolytic ferment in the circulation. If the usually accepted view as to the cause of the rise in the blood sugar during digestion is correct, it would follow that the difference value is due to a substance of alimentary origin, a conclusion opposed to the available evidence. So far as we are aware there is no experimental proof, however, that the increase in the percentage of sugar in the blood after food has been taken is directly dependent upon material absorbed from the alimentary tract, and before proceeding further it seemed advisable to decide the question definitely if possible.

For this purpose, and also for the further investigation of other problems arising in the course of these researches, experiments upon animals under controlled conditions appeared to be necessary and were consequently undertaken.

Summary.

Our results up to the present point may be summarised as follows:—

1. The urine in disease of the pancreas contains an excess of dextrin, which can be measured by the iodine coefficient, and less accurately by the difference value of the urine.
2. The difference value of the blood in pancreatic disease varies directly with the iodine coefficient of the urine and is probably due to the same cause—namely, an abnormal dextrin content.
3. The difference value of the blood, and the iodine coefficient of the urine, are highest in the fasting state and gradually diminish after a meal for about three or four hours, returning to the fasting level after another three or four hours.
4. The difference value of the blood and the iodine coefficient of the urine vary inversely as the percentage of sugar in the blood after a meal.
5. The difference value of normal blood ranges from 0.002 per cent. to 0.008 per cent., and is not appreciably influenced by the ingestion of food.
6. The amylolytic ferment of the blood, and of the urine, is increased in disease of the pancreas proportional to the fasting difference value of the blood and the iodine coefficient of the urine.
7. The amylolytic ferment of the blood and urine in pancreatic disease varies directly with the percentage of sugar in the blood after a meal, and inversely as the difference value of the blood and the iodine coefficient of the urine.

II.—OBSERVATIONS ON THE BLOOD OF DEPANCREATISED ANIMALS.

In order to obtain more conclusive evidence, and to discover, if possible, the means by which the blood and urinary changes are brought about, we arranged a series of experiments upon animals. The operative portion of this work was conducted at the Physiological Institute of University College through the kindness of Professor E. H. Starling, and we take this opportunity of expressing our indebtedness to him for permission to make use of his laboratories for the purpose.

Normal Values.

Some of our experiments were carried out on dogs, others on rabbits, and the first step was to establish normal values for these animals, fasting, and after different test meals had been given. We do not propose to discuss here the influence of various foods on the normal sugar content, difference value, and ferment of the blood in detail as these will be dealt with more conveniently later; it is now only necessary that we should refer to certain fundamental facts which form the basis of the experiments to be described presently.

We found that in the fasting dog the sugar content of the blood averages about 0.09 per cent. After food has been taken the percentage of sugar in the blood gradually rises for some three hours to a maximum of about 0.14 per cent., and then gradually falls to the fasting level, which is reached in five or six hours after the meal. The fasting level in the rabbit is rather

FIG. 6.—Normal dog, meat diet. S, sugar per cent. $\times 1000$; A, Amylolytic ferment per cent. $\times 10$; D, Difference value per cent. $\times 1000$; F, Fasting values; M, Meal.

FIG. 7.—Normal rabbit, mixed diet. S, Sugar per cent. $\times 1000$; A, Amylolytic ferment $\times 10$; D, Difference value per cent. $\times 1000$; F, Fasting values; M, Meal.

more variable than in the dog, ranging from about 0.084 per cent. to 0.086 per cent. in small rabbits, up to 0.094 per cent. to 0.096 per cent. in large "Belgian hares." The effect of feeding is much the same in rabbits as in dogs, a gradual rise in the percentage of sugar in the blood taking place for about three hours, and being followed by a fall to the fasting level during the succeeding three or four hours. As a rule, the maximum figure attained is about 0.16 per cent. The difference value of the blood in both rabbits and dogs is much the same as in man, ranging from 0.002 per cent. to 0.008 per cent. As in the human subject it is not appreciably influenced by feeding. The amylolytic ferment in normal animals is lowest in the fasting condition, averaging about 2 per cent. in both dogs and rabbits. After a meal there is a gradual rise to about 4 per cent. in dogs and 5 per cent. in rabbits in three or four hours, followed by a fall to the fasting level some three or four hours later. Thus, as will be seen from the diagrams (Figs. 6 and 7), the blood sugar curve and the amylolytic ferment curve move in the

same direction after food, while there is a slight tendency for the difference value curve to follow an opposite course.

The Effects of Pancreatectomy in the Dog.

The influence exerted by the pancreas on the blood and urine of the dog was investigated by observing the effects of removing one-third, two-thirds, and practically the whole gland from three animals. All of them recovered satisfactorily from the operation; the wound healed well, and the animals were apparently in good health a week afterwards, when a series of blood analyses were commenced. For each series the dog was fasted for 18 to 24 hours, a sample of the fasting blood was taken for analysis, and it was then given a test-meal. An hour afterwards 3 c.cm. of blood were

0.09 per cent. for sugar, 2 per cent. for the amyolytic ferment, and a 0.006 per cent. difference value. Three weeks after the operation, at which two-thirds (10 g.) of the body and tail of the pancreas were removed, these values had risen to 0.13 per cent. for the sugar, 20 per cent. for the ferment, and 0.170 per cent. for the difference value. There was thus a slightly higher sugar, a marked increase in the ferment, and a considerably lower difference value than in the dog from which only one-third of the gland had been removed when specimens of blood were examined under the same conditions. After a mixed meal of similar composition to that given to the first dog the sugar content of the blood began to rise more quickly, but the maximum level attained was only slightly higher, and the return to the fasting level took longer. The effect of the meal on the ferment and

FIG. 8.—Dog, one-third depancreatized, mixed diet. S, Sugar per cent. $\times 1000$; A, Amyolytic ferment per cent. $\times 10$; D, Difference value per cent. $\times 1000$; F, Fasting values; M, Meal.

FIG. 9.—Normal dog, mixed diet. S, Sugar per cent. $\times 1000$; A, Amyolytic ferment per cent. $\times 10$; D, Difference value per cent. $\times 1000$; F, Fasting values; M, Meal.

FIG. 10.—Dog, two-thirds depancreatized, mixed diet. S, Sugar per cent. $\times 1000$; A, Amyolytic ferment per cent. $\times 10$; D, Difference value per cent. $\times 1000$; F, Fasting values; M, Meal.

drawn from a vein in the ear, and similar specimens were subsequently taken at hourly intervals for five or six hours without any further food being given. Estimations of the sugar content and of the difference value were then made with 2 c.cm. of each sample by the methods previously described, and the remaining 1 c.cm. was used to determine the amyolytic ferment. At the end of the experiment the dog was placed in a metabolic cage, and the urine passed during the 24 hours following the test-meal was collected. This was measured and the total excretion of sugar and the iodine coefficient were worked out.

Removal of one-third of the pancreas.—About one-third (2.7 g.) of the tail end of the pancreas was removed from the first dog. One week after the operation examination of the blood, taken fasting, showed 0.12 per cent. of sugar, a difference value of 0.38 per cent. and an amyolytic ferment of 5 per cent., compared with 0.09 per cent. sugar, a difference value of 0.004 per cent., and an amyolytic ferment of 2 per cent. under the same conditions before the operation. The removal of even a third of the pancreas had thus caused an enormous increase in the difference value, with only a slight rise in the sugar and amyolytic ferment. That this change was not dependent upon the immediate effects of surgical interference with the contents of the abdomen, but resulted from the removal of a portion of the pancreas, is shown by the fact that five weeks later a sample of blood taken after a 24 hours' fast contained 0.10 per cent. of sugar, gave a difference value of 0.30 per cent., and showed an amyolytic ferment of 7 per cent.

The effect of a mixed diet containing about 120 g. of carbohydrate, including 1 ounce of marmalade, was then investigated, with the results shown in Table I.:

TABLE I.

—	Fasting	—	1 hr.	2 hrs.	3 hrs.	4 hrs.	5 hrs.	6 hrs.
Sugar per cent.	0.100	Mixed meal.	0.110	0.130	0.170	0.190	0.140	0.100
Hydrolysis value per cent.	0.400		0.260	0.200	0.200	0.200	0.200	0.280
Difference value per cent.	0.300		0.150	0.070	0.030	0.010	0.060	0.180
Amyolytic ferment per cent.	7		7	13	17	30	12	10

The relation of these figures is seen in the chart. (Fig. 8.) For comparison the results obtained with a normal dog on the same diet, drawn to the same scale, are also shown. (Fig. 9.)

Removal of two-thirds of the pancreas.—The dog on which this operation was performed had normal fasting values of

former rising more quickly and to a much higher level than in the dog from which one-third of the pancreas had been removed, and the latter falling more rapidly until almost a normal value was found at the third hour; the subsequent rise in the difference value was also much slower. The figures obtained in this experiment were as shown in Table II.:

TABLE II.

—	Fasting	—	1 hr.	2 hrs.	3 hrs.	4 hrs.	5 hrs.	6 hrs.
Sugar per cent.	0.130	Mixed meal.	0.140	0.170	0.190	0.190	0.176	0.150
Hydrolysis value per cent.	0.300		0.180	0.190	0.200	0.200	0.190	0.180
Difference value per cent.	0.170		0.040	0.020	0.010	0.010	0.014	0.030
Amyolytic ferment per cent.	20		30	35	40	40	37	32

These results are represented graphically in the chart. (Fig. 10.) In the 24 hours following the test diet the one-third depancreatized dog passed 300 c.cm. of urine containing 0.3 per cent. of sugar and with an iodine coefficient of 20 per cent., giving total excretions of 0.9 g. of sugar and 60 iodine coefficient units. The two-thirds depancreatized dog excreted 500 c.cm. of urine containing 0.7 per cent. of sugar and with an iodine coefficient of 10 per cent., working out at 3.5 g. of sugar and 50 iodine coefficient units for the 24 hours. The dog from which the larger proportion of the pancreas had been removed therefore passed more sugar, but less dextrin, in the same space of time when they were on similar diets, results corresponding to the higher level of the sugar curve and the lower difference values obtained with the blood.

TABLE III.

—	Fasting	—	1 hr.	2 hrs.	3 hrs.	4 hrs.	5 hrs.
Sugar per cent.	0.190	Mixed meal.	0.210	0.240	0.300	0.500	0.400
Hydrolysis value per cent.	0.200		0.210	0.240	0.300	0.500	0.400
Difference value per cent.	0.010		0.000	0.000	0.000	0.000	0.000
Amyolytic ferment per cent.	50		60	65	70	85	75

Total pancreatectomy.—Practically the whole of the pancreas (17.5 g.) was removed from this dog at one operation. It made a good recovery, and, although losing weight and passing typical fatty stools, remained lively and free from complications until death from diabetic coma, experimentally induced, occurred a fortnight later. Careful dissection post mortem showed only 0.2 g. of pancreatic

tissue remaining. Three days after the operation the fasting blood was found to contain 0.19 per cent. of sugar, with an amylolytic ferment of 50 per cent. and a difference value of 0.010 per cent. A mixed meal, of the same composition as that given to the other two dogs, next day brought about the changes in the blood values shown in Table III.

In graphic form these results are represented, on the same scale as for the other two dogs, in the chart. (Fig. 11.) It will be seen that total removal of the pancreas induced a much higher level of sugar in the blood, both fasting and after the test meal, than in either of the other two animals. The output of sugar in the urine was correspondingly

FIG. 11.—Dog, totally depancreatized, mixed diet. S, Sugar per cent. $\times 1000$; A, Amylolytic ferment per cent. $\times 10$; D, Difference value per cent. $\times 1000$; F, Fasting values; M, meal.

and amylolytic ferment, both fasting and after a meal. They also show that the difference value of the blood and the iodine coefficient of the urine are related to the functional activity of the pancreas. When this is interfered with the difference value rises to abnormal heights, the increase being greatest in the fasting condition and in the earlier stages of pancreatic insufficiency. After a meal, and as the functions of the pancreas are less efficiently performed, the difference value of the blood diminishes again, so that when practically the whole of the gland is removed, with consequent very pronounced hyperglycemia and glycosuria, the difference value drops to almost the normal level during fasting and disappears entirely for some hours after a meal. It would seem, therefore, that an increase in the difference value of the blood and in the iodine coefficient of the urine above normal values indicates an early stage of defective carbohydrate metabolism due to interference with the functions of the pancreas, but that as the defect increases and frank hyperglycemia and glycosuria develop the difference value and iodine coefficient fall to a corresponding degree—that is to say, an abnormal increase in the difference value of the blood or in the iodine coefficient of the urine is a sign of a prediabetic condition dependent upon a defect in the functional activity of the pancreas. A similar conclusion was arrived at by one of us on clinical grounds in 1913, when the history of a case of chronic pancreatitis, which eventually became diabetic, was described.¹² It was then shown that the iodine coefficient in the urine increased as the disease progressed, until glycosuria developed, when it gradually fell as the excretion of sugar became larger.

The fact that the difference value and the sugar content of the blood move regularly in opposite directions, both after a meal and as the functional capacity of the pancreas diminishes, points to their having a common origin and being controlled by the

same influences. One controlling influence which determines their relation appears to be the functional activity of the pancreas, and although the increase in the difference value in the earlier stages of pancreatitis, or when a small portion of the gland is removed, with the subsequent fall which occurs as the cirrhotic changes in the gland advance, or more of the organ is removed, might suggest that the substance in the blood on which the difference value depends is derived from the pancreas itself, this would not explain the relation of the difference value to the sugar or account for the rapid fall during digestion. Further, it does not seem likely that the dextrin-like bodies giving rise to the iodine coefficient in the urine, and probably the difference value of the blood, would be set free in the circulation in sufficient amount to explain the results obtained.

The simplest explanation of the difference value of the blood, and the iodine coefficient of the urine, would be the presence in the peripheral circulation of dialysable dextrans absorbed from the alimentary tract, and that this may be a partial cause under certain circumstances is shown by the effect of feeding a depancreatized dog on a diet of dextrinised oatmeal. On comparing the chart (Fig. 12) representing the blood changes after a meal of dextrinised oatmeal in a dog from which two-thirds of the pancreas had been removed with the chart from the same dog after a mixed meal (Fig. 8), it will be seen that, although the sugar curves are much the same in amplitude, the difference value curve after the oatmeal is slower in falling, and does not reach the same low level as when a mixed meal was taken, suggesting that more hydrolysable carbohydrate was passing into the peripheral circulation in the former case than in the latter. When, however, the same experiments were tried with a totally depancreatized dog similar difference value curves were obtained with dextrinised oatmeal and with a mixed feed. This, with the fact that a meal of meat only (Fig. 13) gave the same difference value curve as a mixed meal containing carbohydrate in all the dogs, points to the comparatively slight variation following dextrinised oatmeal in the one-third and two-thirds depancreatized dogs being only a partial and exceptional cause of the difference value in the blood and not the usual explanation.

A study of the portal and peripheral blood taken from rabbits after fasting for 24 hours, three hours after a meal of dry oatmeal and three hours after being fed on dextrinised oatmeal, offers an explanation of the variations in the results obtained with these foods, and incidentally shows that a considerable proportion of a thoroughly cooked starchy food is absorbed into the portal blood in the form of dextrans and maltose, whereas an uncooked starch is almost completely broken down to dextrose before it appears in the portal vein. One set of experiments gave the results shown in Table IV.:

TABLE IV.

Sugar per cent. ...	0.090	0.150	0.156	0.094	0.240	0.300
Hydrolysis value per cent. ...	0.092	0.154	0.160	0.096	0.250	0.500
Difference value per cent. ...	0.002	0.004	0.004	0.002	0.010	0.200

From these figures it will be seen that, while the difference value of the mesenteric blood is increased five times after a meal of dry oats, it is increased a hundredfold by a feed of dextrinised oatmeal, whereas the sugar value is only increased about two and a half times and three times respectively, suggesting that a large proportion of the dextrinised food is absorbed into the portal circulation in a hydrolysable form and not as dextrose. Actual analysis of the mixed blood from one set of rabbits taken after a feed with dry oats and of another set after a meal of dextrinised oatmeal confirmed these conclusions, for the proportion of dextrose

¹² XVII. Int. Cong. of Med., London, August, 1913, Med. Sect., p. 305.

in the latter was found to be considerably less than the proportion of dextrose in the former, while the percentages of dextrin and maltose were much increased, especially the dextrin, as shown by the figures in Table V.

TABLE V.—Analysis of Portal Blood.

	Dextrose per cent.	Dextrin per cent.	Maltose per cent.
Dry oats	96	1.6	2.4
Dextrinised oatmeal	60	25.0	15.0

Most of the dextrose and nearly all the hydrolysable carbohydrate are apparently stopped in the liver, however, for on comparing the figures given by the blood from the marginal vein it will be seen that the percentage of sugar is practically the same after both dry oats and dextrinised oatmeal, and that it is only increased above the fasting value about one and a half times against two and a half times and three times in the mesenteric blood for dry oats and dextrinised oatmeal respectively. A still larger proportion of the hydrolysable carbohydrate appears to be retained in the liver, for the difference value of the blood from the marginal vein was only doubled after both feeds, though mesenteric blood taken at the same time showed a hundredfold increase in the difference value after the dextrinised food. It is therefore evident that as long as the liver is functioning normally the ingestion and absorption of dextrinised starches exert comparatively little influence on the difference value of the peripheral blood. Another argument in support of this conclusion is that the highest difference value in depancreatised dogs is found in the fasting condition, the reverse of what one would expect if it

FIG. 12.—Dog, two-thirds depancreatised, dextrinised oatmeal diet. S, Sugar per cent. $\times 1000$; A, Amylolytic ferment per cent. $\times 10$; D, Difference value per cent. $\times 1000$; F, Fasting values; M, Meal.

injected into the marginal vein of another fasting rabbit after a sample of blood had been taken for analysis. Subsequently specimens of blood were taken at half-hourly intervals for two hours and analysed with the results shown in Table VI.

TABLE VI.

	Fasting	—	$\frac{1}{2}$ hr.	1 hr.	$1\frac{1}{2}$ hrs	2 hrs.
Sugar per cent.	0.086	Injection 2 c.cm. pancreatic ext.	0.080	0.070	0.080	0.086
Hydrolysis value per cent.	0.090		0.080	0.070	0.080	0.086
Difference value per cent.	0.004		0.000	0.000	0.000	0.000
Amylolytic ferment per cent.	2.0		2.0	2.0	3.0	2.0

The injection gave rise to no apparent discomfort, and was not associated with any lowering of temperature or signs of shock, but the sugar content of the blood was depressed below the fasting level, and at the end of an hour stood at a figure far below any we have ever met with in a normal rabbit. Within half an hour of the injection the normal fasting difference value of 0.004 per cent. had disappeared, and it had not returned when the experiment was concluded. These effects are well seen in the chart. (Fig. 14.)

In order to exclude the influence of injected proteins and to demonstrate the dependence of the changes observed on ferment action we carried out a control experiment with another portion of the same extract which had been boiled and cooled previous to injection. This was found to have no effect on either the sugar or difference value of the blood, which remained at the fasting levels.

Taking these results in conjunction with the blood changes following pancreatectomy it seems probable that the pancreas exerts an inhibitory action on

FIG. 14.—Normal rabbit, pancreas extract intravenously. S, Sugar per cent. $\times 1000$; A, Amylolytic ferment per cent. $\times 10$; D, Difference value per cent. $\times 1000$; F, Fasting values; P, Pancreas extract injected.

were directly dependent upon carbohydrate material absorbed from the alimentary tract.

By a process of exclusion we are driven to the conclusion that the difference value of the peripheral blood arises from the presence of a hydrolysable carbohydrate, or carbohydrates, derived from the glycogen stores of the body, and of these the liver, being the largest, and as we have seen the situation in which such material coming from the intestine is held up, is probably the most important. The question which then arises is, What is the relation existing between the pancreas and liver, and why does the removal of a portion of the pancreas increase the difference value of the blood, whereas total pancreatectomy reduces it?

Injection of an Extract of the Pancreas.

Before discussing the possible answers to these questions, which might be based upon the effects of diminishing the physiological influence of the pancreas by excising portions of the gland, it is advisable that we should consider the results produced by the opposite procedure—namely, increasing it by injecting a fresh extract of the pancreas.

The pancreas of a fasting rabbit was removed as completely as possible immediately after death, cut up finely, and half of it ground in a mortar with 10 c.cm. of Locke's solution and sand. The resulting emulsion was then centrifuged and 2 c.cm. of the clear supernatant liquid were

glycolysis, regulating the breaking down of stored carbohydrate into sugar and intermediate products by means of a ferment which is destroyed by heat. When the influence of the pancreas is completely removed, as in total pancreatectomy, stored and ingested carbohydrate is converted entirely into sugar by the uncontrolled activity of the glycolytic ferment of the tissues, with resulting marked hyperglycæmia and a normal or sub-normal difference value in the blood; when the functions of the gland are only partly interfered with, as in partial pancreatectomy, the first stage in the breaking down of glycogen is still abnormally active, so that an excess of the intermediate products of glycolysis, in the shape of dextrins, pass into the circulation, but the restraining influence of the pancreas is now sufficient to prevent further conversion to sugar, consequently the difference value of the blood rises, but the percentage of sugar is not appreciably affected; when, as in the injection experiments just described, the controlling influence of the pancreas is increased, on the other hand, the opposite effect to pancreatectomy is produced, the normal conversion of glycogen into simpler forms of carbohydrate which goes on even in the fasting condition being interfered with, so that dextrins disappear from the blood and the normal percentage of sugar is diminished.

The Amylolytic Ferment of the Blood.

We have previously pointed out that the amylolytic ferment content of the blood varies in pancreatic disease in the human subject directly with the percentage of sugar and inversely as the difference value. A study of the effects of pancreatectomy in dogs shows that this relation holds good under experimental conditions also. The figures and charts given in the second part of this paper demonstrate that as a larger proportion of the pancreas is removed, and the percentage of sugar in the blood rises, the percentage of amylolytic ferment increases correspondingly. Thus in a normal dog, when fasting, the amylolytic ferment of the blood averages about 2 per cent., when one-third of the pancreas had been removed we found 7 per cent., after the removal of two-thirds of the gland it had risen to 20 per cent., and in a dog from which the whole of the pancreas had been removed a fasting level of 50 per cent. was obtained. The corresponding sugar values of the blood rose from 0.09 per cent. for the normal dog to 0.10 per cent. for the one-third depancreatized animal, then to 0.13 per cent. for the two-thirds pancreatectomy, and finally to 0.19 per cent. after total pancreatectomy. The difference value, on the other hand, after an initial rise from 0.002 per cent., or thereabout, for the normal dog to 0.300 per cent. after the removal of one-third of the pancreas, fell to 0.170 per cent. when two-thirds of the gland were excised, and then to 0.010 per cent. after the whole organ had been removed. Such a constant and intimate relation between these values suggests that the percentage of sugar and the difference value of the blood are dependent upon the amount of amylolytic ferment. As long as the amylolytic ferment ranges within normal values the percentage of sugar does not exceed the normal limit of 0.15 per cent. and the difference value varies between 0.002 and 0.008 per cent., but when the amylolytic ferment rises to abnormal heights the breaking down of stored carbohydrate is accentuated. In the early stages, while the amylolytic ferment is only moderately increased, the intermediate products of glycolysis (dextrins) appear in the blood in abnormal amounts, but when the amylolytic ferment rises still higher these intermediate products are further broken down and the percentage of sugar steadily rises as they diminish, until finally all carbohydrate passing into the circulation does so in the form of dextrose. A relationship of the same type is seen in normal animals after a meal, and still better in one from which a small portion of the pancreas has been removed, for, as will be seen from the charts (Figs. 6, 7, 8, 9), the amylolytic ferment rises after food has been taken and with this rise there is a corresponding increase in the percentage of sugar and a fall in the difference value.

As the pancreas is the gland from which the amylolytic ferment required for the digestion of starches in the alimentary tract is chiefly derived it is tempting to assume, as has generally been done, that the amylolytic ferment of the blood and urine is also of pancreatic origin, but the evidence of our experiments is opposed to such an inference, for it is inconceivable that the ferment should appear in increasing amount as the organ from which it is supposed to be derived is diminished in size and that it should be at a maximum when the whole gland has been excised. There must therefore be some other origin for the amylolytic ferment of the blood, and the liver seems the most likely source. Since the days of Claude Bernard it has been known that the liver possesses glycolytic powers and that if the liver of an animal is kept at body temperature after death the contained glycogen quickly disappears and is replaced by sugar. The rapidity of this transformation after death and its comparative slowness during life have never been satisfactorily explained. Our experiments seem to offer a solution, and this lies in the antagonism between the internal secretion of the pancreas and the amylolytic ferment of the liver, the latter inducing glycolysis and the former restraining it: in other words, the internal secretion of the pancreas functions as a brake on the glycolytic activities of the liver ferment.

Perfusion of the surviving liver.—To test the validity of this view in another way we proceeded to carry out experiments with the "surviving" livers of rabbits,

perfusing one series with Locke's solution, and another with a similar solution containing an extract of fresh pancreas prepared as in the previously described injection experiments.

The fluid flowing from a cannula in the superior vena cava was collected in each experiment for periods of 15 minutes at a time for 75 minutes. The total sugar and difference value for each period were worked out and, after the glycogen remaining in the liver had been determined at the end of the experiment, the percentage of glycogen, sugar, and difference value for each 15 minutes were calculated. The average result of three perfusions with the plain Locke's solution are shown in the diagram (Fig. 15) by light lines and the results of perfusion with Locke's solution containing fresh pancreatic extract are indicated by heavy lines.

Fig. 15.—"Surviving liver" perfusions with plain Locke's solution (light lines) and with added pancreatic extract (heavy lines). Normal averages: Sⁿ, Sugar per cent.; Dⁿ, Difference value per cent.; Gⁿ, Glycogen per cent. Pancreas extract: S^p, Sugar per cent.; D^p, Difference value per cent.; G^p, Glycogen per cent.

It will be seen that the addition of an extract of pancreas to the perfusion fluid caused an appreciable reduction in the amount of glycogen broken down. The output of sugar was diminished, but the difference value was considerably increased. These experiments with the surviving liver, therefore, lend support to the view that the pancreas exerts a restraining influence on the glycolytic ferment of the liver, interfering with the breaking down of glycogen and causing a relative increase in the production of the intermediate hydrolysable derivatives, with a diminution in the normal end-product, reducing sugar. As the perfused extract was prepared from the whole pancreas, and consequently contained the zymogen of the external as well as the internal secretion of the gland, the possible effect of the former must be taken into account, and it may be that its presence accounts to some extent for the very considerable increase in the difference value.

Summary.

The animal experiments described confirm the conclusions arrived at on clinical grounds. In addition they show that:—

- (1) The rise in the difference value of the blood resulting from interference with the functions of the pancreas insufficient to produce frank hyperglycæmia and glycosuria, diminishes as the volume of the gland is further reduced and the percentage of sugar in the blood and the excretion of sugar in the urine rise.
- (2) The hydrolysable substance in the blood on which the difference value depends appears to be derived chiefly from the glycogen stores of the liver, and is an intermediate soluble product (dextrin) formed in the conversion of glycogen to sugar.
- (3) The liver contains an amylolytic ferment which passes into the blood and urine, and it is as a result of its activity that the glycogen of the liver is broken down.
- (4) The pancreas exerts a restraining influence on the glycolytic ferment of the liver, probably through its internal secretion.
- (5) Normally, the balance between the glycolytic ferment of the liver and the internal secretion of the pancreas is maintained in such a way as to keep the

percentage of sugar, and the difference value of the blood, within well-defined limits; when this balance is interfered with abnormal relations result.

(6) A relative increase in the pancreatic secretion causes a fall in the percentage of sugar and in the difference value of the blood.

(7) A relative diminution in the secretion of the pancreas, with consequent greater liberty of action on the part of the glycolytic ferment of the liver, gives rise in the early stages to an increased formation of the intermediate products of glycogen degradation without any change in the sugar, and in the later stages to an increasing sugar production with a proportional diminution in the intermediate products.

(8) The appearance in the blood and urine of intermediate products of carbohydrate metabolism, as shown by the difference value of the blood and the iodine coefficient of the urine, indicates a prediabetic condition which, if allowed to progress unchecked, will be followed by hyperglycæmia and glycosuria.

(9) Incidentally it has been shown that a considerable proportion of a well-boiled starch is absorbed into the portal circulation in the form of dextrins and maltose, whereas an uncooked starch enters the portal blood chiefly as dextrose.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

THE ANTIDIURETIC EFFECT OF

PITUITARY EXTRACT IN DIABETES INSIPIDUS.

BY MAURICE DAVIDSON, M.A., M.D. OXON.,
M.R.C.P. LOND.,

PHYSICIAN TO OUT-PATIENTS, ROYAL WATERLOO HOSPITAL FOR CHILDREN AND WOMEN.

IN April, 1919, there appeared in the *Quarterly Journal of Medicine* an interesting account of some observations by Drs. E. L. Kennaway and J. C. Mottram upon the antidiuretic effects of pituitary extract in diabetes insipidus with a detailed account of two cases. In view of the comparative rarity of this condition I now record the following notes of a case recently under my care in which injections of pituitrin were given, and observations made upon the total output of urine in the 24 hours, as well as notes on the amount and specific gravity of the samples collected at frequent intervals after the injections. The injections were always followed by an action of the bowels, and on the first occasion by vomiting, but except for this no untoward effects were observed. Apart from the discomfort and annoyance of the symptoms the patient suffered no inconvenience beyond that of a slight bronchitis, which yielded to treatment. There were no symptoms or signs to suggest any associated disorder of the pituitary gland.

The patient, an ex-soldier, aged 35, was admitted to the wards of the Miller General Hospital on May 21st, 1920. He gave the following history. He had always been a healthy man until he was invalided from the Salonika front in the winter of 1917 with bronchitis and nephritis (*sic*). He was sent back to England, and while in hospital at Malta, en route, he began to complain of polyuria for the first time. He was treated for bronchitis and asthma, but no special attention was paid to the other condition.

On admission to the Miller Hospital his condition was as follows:—He was a healthy looking well-developed man. He complained of some cough and of great thirst, and continual polyuria. On examination he had signs of some bronchitis; medium rhonchi were audible all over both lungs without moist sounds; there was a moderate amount of expectoration. He was treated for this with belladonna and stramonium, and the physical signs in the chest cleared up. The heart was normal. There was no sign of oedema of the face or legs, nor was there any albuminuria. His visual fields were not diminished; the appearance of the fundus oculi on both sides was normal. A skiagram of the skull showed no abnormality of the sella turcica. From the time of his admission he suffered continually from intense thirst, and was allowed as much water as he wanted day and night. The urine was pale, acid in reaction, of low specific gravity (1000), and contained no sugar or albumin. The amount passed per 24 hours averaged just over 300 oz.

It was decided to administer hypodermic injections of pituitary extract in order to observe its effect upon the diuresis, and to see whether after continuing the injections for some time any permanent or lasting

effect was obtained. The results are shown in Table I. It will be seen from this table that the antidiuretic effect of the pituitrin was such as to cause an appreciable diminution in the total excretion of urine in the 24 hours. The effect was much more pronounced during the period shortly following the injections as may be seen from the record of the hourly collection of

specimens of urine. (Table II.) After June 3rd (thirteenth day after admission) several doses of pituitrin were given by the mouth, but without any appreciable effect upon the amount of urine secreted. The polyuria continued, the man's general condition being satisfactory and the bronchitis and asthma having completely cleared up. He was discharged from hospital in order to go for a short time into a convalescent home.

Winpole-street, W.

AN INFANT AMAZON

BY D. S. PRACY, L.R.C.P. LOND., M.R.C.S. ENG.

COMPLETE absence of the breast in a female infant appears to be a very rare occurrence, and the following case may therefore be worthy of record.

Mrs. K., multipara, was delivered on March 25th, 1920, of a full-term, healthy female child, of 9 lb. weight. On

examination of the infant I found that there was complete absence of the left breast and nipple, and absence of the major part of the anterior axillary wall, due to absence of the costo-sternal portion of the great pectoral muscle.

The accompanying illustration shows the child at the age of 6 weeks.

Atherstone.

Medical Societies.

MEDICO-PSYCHOLOGICAL ASSOCIATION OF GREAT BRITAIN AND IRELAND.

Annual Meeting.

At the seventy-ninth annual meeting of the Medico-Psychological Association, held at the Mental Hospital, Cheddleton, and at the Town Hall, Buxton, Dr. BEDFORD PIERCE, the retiring President, was in the chair. There was a large muster of members, and an unusual feature was the excellent concert given in the recreation hall of the Mental Hospital by the orchestra, of which Dr. W. F. Menzies is conductor.

The Minimal Requirements for a Small Clinical Laboratory.

Dr. W. G. THOMSON read a paper on this subject, in which he discussed the best way to set about providing the apparatus needed for routine investigations on nerve tissue, blood, cerebro-spinal fluid, and excreta, and for clinical tests in institutions at which there is no whole-time expert pathologist. The minimal cost of such equipment he estimated at £115.

Dr. TOM WILLIAMS (Washington, D.C.) spoke of the method carried out in America for centralising the laboratory and teaching work of a number of asylums in the same State; and said that members of the asylum staffs periodically attended these centres.

Dr. J. MIDDLEMASS spoke of the great benefit of being able to conduct routine examinations at one's own hospital. Simple examinations of the cortex of the brain, in his own experience, had cleared up many obscure cases. Every asylum would be the better for some such equipment as Dr. Thomson had indicated.

Lieutenant-Colonel E. W. WHITE proposed that the cordial thanks of the Association be tendered to Dr. Bedford Pierce, the retiring President, and also to the other officers for their services.—Dr. J. B. SPENCE seconded, remarking specially on the work of the Registrar (Dr. A. Miller), and the secretary (Dr. R. Worth).—Dr. BEDFORD PIERCE replied.

THE PRESIDENT, in introducing Dr. W. F. Menzies, superintendent of the Mental Hospital, Cheddleton, as President for the coming year, extolled his thoughtful work in the specialty, and his many services for the Association.

Presidential Address: The Mechanism of Involutionary Melancholia.

Dr. MENZIES then gave an exhaustive address on this subject. He said that at the present time, when the claims of psychogenic treatment were attracting even the lay mind, it befitted those who believed that beneath every mental process there was a mechanical basis to ask themselves whether they were quite blameless if easily understood psychological explanations were substituted for the much more intricate and complex physiological ones. Had alienists always applied to the problems of nervous physics all the available knowledge? Twenty years ago Crookshank endeavoured to correlate physical signs with mental conditions, and 15 years later Dunlop Robertson drew attention to the importance of adrenalin in the production of depression. Those engaged in this specialty should be willing to apply to it the simpler tests of the physiologist and the chemist. The type of illness he had chosen for this address comprised two distinct processes, and his aim was, by tracing the conditions present in both, to offer some explanations as to the proximate causes underlying: (1) involution, and (2) depression. The psychology of melancholia was the depressive emotion; the anatomy of the depressive emotion was a sympatheticotonus, and the chemistry of the latter was an endogenous anoxæmia. Dr. Menzies expressed his indebtedness for clinical and laboratory observations to Dr. W. D. Wilkins and Dr. W. G. Thomson. At the involutionary period a most important factor was excessive intestinal putrefaction. This needed consideration, for though constipation and

dementia were common in old age, only a few old people were depressed. Intestinal stasis was certainly very common among the insane, and bands and fine adhesions were evident when looked for; and he reminded the meeting of the theory of Sir William Arbuthnot Lane as to the causation of these. Yet in young neurotic persons it was sometimes possible to make out an undue breadth of colon, unequal dilatation of stomach, with exaggerated flexion at the angular notch, and tonic contraction of one or other rectus muscle, though a daily emptying of the bowel took place. Keith believed that enterostasis was due to nodal segments, and Dr. Menzies thought that both Keith and Lane might be right. He then entered on a lengthy consideration of the various digestive products elaborated in the intestine and of the views generally held about them. To understand the connexion between bacterial absorption and melancholia it was essential to have an anatomical basis to work upon, and that basis existed in the involuntary nervous system; its importance could not be over-estimated. In regard to the physiology of the emotions, it had long been recognised that fear could cause certain superficial presentations, but only comparatively recently had systematic efforts been made to trace the technique, especially by Pavlov, Hornberg, Müller, and Bickel. The next step was to show that the inhibition caused by the emotional impulses was closely connected with the activity of the involuntary nervous system. Bayliss and Starling proved that all the phenomena of digestion in the mouth, stomach, and duodenum could be stimulated if an acid fluid were applied to the duodenal mucous membrane after the nerves had been divided, showing that another important factor was at work in body processes; this factor was named the action of hormones. The sympathetic system could generally overcome the autonomic, but did not persist so long. Cannon considered that the autonomic system quietly built up the body reserves against a time of stress, its operations having but little effect on the tone. Many phenomena produced by emotion and by the nervous outflow from the involuntary system were closely duplicated by the effects of adrenalin, as Oliver and Schäfer showed in 1894. Dr. Menzies proceeded to recount the physiological properties which had been observed to follow the giving of adrenal extract, from which it was clear that an emotional outflow was at one with the sympatheticotonus and was accompanied by an increase of adrenalin acting as a hormone. It had long been known that severe emotion produced diabetes, and a large number of observers noted that glycosuria was common in melancholia, the amount of sugar in the urine varying with the degree of depression. Glycosuria was easily produced in excited cats, and it was often found in football players and in some of the spectators. A better indication, however, was derived from an estimation of the blood sugar. In melancholia alone was glycæmia unduly high before meals.

Dr. Menzies next considered the conduction of nerve impulses before they reached the cerebral cortex and the possible paths by which those subserving feeling-tone might travel. Head's brilliant conceptions of the nature of sensation had added a new chapter to the science of neurology, and these he discussed fully. Ramsey Hunt had enunciated the theory that two distinct systems of motor fibres to skeletal muscles exist—(1) the paleokinetic, to the sarcoplasmic substance, associated with slow tonic contraction; (2) the neokinetic, to the sarcostyles, associated with the quick, spasmodic, "voluntary" contraction. Hunt held that the principle was carried right through from the periphery to the centre, and was also represented in the cerebellum, and clinical evidence was adduced from the observed differences between the two forms of muscular hypertonus. The matter could not, however, yet be regarded as settled. Dr. Menzies then discussed the various paths separately, and proceeded to consider the question of thalamic sensations. Head codified the nature of thalamic sensations and showed that partial interruption of the thalamocortical path had a profound influence in releasing sensations registered in the thalamus from the inhibitory effects

of cortical activity. Normally, all sensations reaching the thalamus were subjected to minute analysis in the cortex and allowed or censored after judgment had been passed. But in certain diseased conditions either the connecting path was impaired, or the cerebral cortex was unfit to function, and then the sensation rose to the dignity of an emotion, which could be regarded as a temporary flood in a stream of feeling-tones. All feeling-tones did not eventuate in emotion, nor were all defensive emotions tornadoes; they might develop slowly, and last for weeks, even months, and such a condition constituted depression. In melancholia there appeared to be a chronic hyperadrenalism. He went on to review the signs present in states of depression, and considered next the exaltive emotion. The thalamus was the centre which presided alike over the depressive and exaltive feeling-tones and emotions.

After considering the functions of the cerebral cortex, the Betz cells, the layers of the cortex, the pre-Rolandic cortex, the post-Rolandic cortex, Dr. Menzies proceeded to consider the cortex in disease, remarking that our chief knowledge of the course followed by the cerebro-spinal fluid had been gained by observing the process of brain atrophy, and the distribution of the areas of wasting in dementia. It was plain, he said, that involuntary processes were independent of the mental state which might accompany them, though both, in some cases, might be dependent on the same causes. Involution was a march of gradually increasing cytolysis, and appreciably depended upon the power of reaction of the hepatic antitoxins to the intestinal toxins, the penalty of failure being defective oxidation. What was known as melancholia depended on modifications of the same processes, especially on excessive bacterial fermentation and enterostasis. Alienists were now, apparently, on the way to a better understanding of the problems underlying the origin of the psychoses. Science waited upon the chemist, who, in turn, waited upon the clinician; cases must be observed with a more scientific eye. At the present time more kudos was to be gained from selling a sow than from sensitising a serum, from taking twopence off the maintenance rate than from discovering how dysentery was propagated. The man of science had ever been the Cinderella of the profession, and the beggarly salary of a head clerk was supposed to be sufficient for a brilliant pathologist. But there was now a dawn on the horizon; the war had cast over the art of medicine a new spirit, and the brilliant results attained in preventive fields by organised research had proved that money so spent was a good investment to the nation. The Board of Control had commenced a campaign, so that it was hoped that before many years each mental hospital would have its triad of trained observers—pathologist, biochemist, clinician. In conclusion, Dr. Menzies said he had suggested a few problems which he hoped might raise curiosity and criticism.

Some Determinants of Morbid Emotionalism.

On Wednesday morning, at the Town Hall, Buxton, with the President in the chair, Dr. WILLIAMS gave a contribution on this subject. He said emotility was, until the present century, dealt with in a purely introspective and observational manner. It was difficult to understand how there could be reactivity without that state of feeling which was known as emotility; even a unicellular organism, which had no differentiated nervous system, must have a state of feeling at the moment of being repelled by a stimulus. And on passing up the animal scale we could observe the difference between the manifestation of a state of feeling or emotion and the more purely purposive manifestations which were regarded as associated with the cerebro-spinal nervous system. An emotion was the function of the whole organism. The individual who was not emotive was morbid, abnormal. He went on to explain the states which he regarded as indicating morbid emotility, from the ordinary "blues" of a temporary character to more serious states, especially the "phobias," who had met with a series of circumstances which they had been unable to transcend. In these cases the emotion did not cease as soon as its determinant ceased. He

described his process of re-education aimed at the cure of the condition.

The Value of Psychoanalytic Teaching.

There were then submitted to the meeting three contributions on psychoanalysis. The first was by Dr. W. H. B. STODDART and was entitled "A Brief Résumé of Freud's Psychology." He considered Freud the greatest psychologist who had ever lived. An unpleasant memory was not thrown away into space, but could be revived by such processes as hypnotism and psychoanalysis. The driving of unpleasant thoughts deeper into the mind was known as "repression," an automatic mechanism to protect the individual from intolerable thoughts. A constellation of repressed ideas was known as a "complex" and inhabited the unconscious mind. But a desire which had been banished from the conscious was constantly striving for recognition and gratification. As the conscious would not allow this, such gratification must be achieved in a distorted guise; it was sublimated in various activities. If the patient did not remain normal he gratified his complexes by the creation of symptoms. Neuroses, psychoses, and dreams were fundamentally the same, the only difference being that the neurotic or psychotic lived his dream. Freud held that forgotten infantile desires and interests remained permanent throughout life, and that many adult activities owed their energy to primitive infantile impulses; any neurotic or psychotic manifestation among members of his own family, especially the father or mother, had a profound effect on the mental development of the child. With regard to the sexual problems Freud did not really extend the meaning of the word sexual to include the young child; he merely recognised certain infantile activities to be of a sexual nature, because they would be regarded as sexual by everybody if they occurred in an adult. Freud would be the first to admit that such activities were quite innocent in a child. Opposition to this belief was largely due to the topic of sex being taboo. Sexual indulgence was regarded as a crime except in wedlock. Sexual topics were far more banned than those of theft, murder, and other crimes. Yet engagements and marriages were of great interest to the very people who banned intimately sexual topics. The outcome of this banning was found in certain data regarding the sexual perversions—homosexuality, masochism, sadism, fetishism, masturbation. An enormous number of people were homosexual without knowing it. Probably Freud was right when he said nobody was quite normal sexually; hence repression achieved the force of an inborn instinct. Professor Clifford Allbutt, in his recent presidential address at Cambridge, expressed his thankfulness that it did not fall to his lot to seek for pearls in that sty, and although the professor prepared a public criticism of the method he did not even take the trouble to learn anything about it. Dr. Stoddart hoped members of this association would not be led from the path of scientific investigation by sentimental objections based on their own psychic make-up. He proceeded to point out that in psychoanalysis the analyst said nothing; he only encouraged the patient to unfold his own story.

Homosexuality.

Dr. C. STANFORD READ read a paper on Homosexuality. The revolt of the moral sense against the idea of homosexuality was attributed by Freud in great part to the existence in the ordinary mind of a homosexual component of the sex instinct, which found indirect expression in the condemnation of homosexuality in others. But man was not the purely reasoning individual he believed himself to be: he was largely swayed by unconscious emotional forces which warped his thought and action. A study of the perversion was necessary to the mental physician for an understanding of the human problems with which he had to deal. He hoped the present wider study of Freudism would arouse a discontent with the old more or less purely descriptive psychiatry. Homosexuality in its conscious form, when it was carried into overt action, was far more prevalent than was usually supposed. It was needful to differentiate the passive from the active

form; the first was a developmental abnormality, the latter was acquired in the course of mental growth, and must be considered as a neurosis. He proceeded to elaborate the Freudian doctrine, pointing out the connexion between paranoia and latent homosexuality, and showing that psychoanalysis would explain the delusions of persecution, jealousy, erotomania, and grandeur seen in paranoia. Alcohol tended to destroy sublimation and aid regression, and thus might set free early trends, of which homosexuality was found to be a common one. He concluded with an appeal for a careful and unprejudiced study of Freud's contentions, which had been arrived at by long research and observation.

Sadism and Masochism.

Dr. REES-THOMAS read a contribution on this subject. He said that in sadism was included everything from an impetuous attitude towards the sexual object to the stage in which sexual gratification ultimately depended upon the complete subjugation and ill-treatment of the sexual victim. Masochism, on the other hand, ranged from mere subjugation to the sexual object to the suffering of physical or mental pain as a condition of sexual pleasure. This paper treated of these in their broad meaning. Bloch referred to these conditions as affecting mankind in the mass, as shown by gladiatorial combats, revolutions, marriage by capture, cannibalism, &c. He spoke of the relationship of muscular exertion to sexual excitement, and of intensity of feeling causing an overflow to other impulses, and thought this might be a factor in the later formation of sadistic impulses. He quoted illuminating instances, from his own experience, of the truth of Freud's contentions. He contended that the step from the psychic state of the normal lover to that of the sadist was but a short one. Usually sadism and masochism were found side by side in the same individual. Active and passive cruelty must be recognised as almost universal, and it acted, in greater or less degree, in influencing and colouring the sexual abnormalities and psychoses.

Psychoanalysis and the Psychoses.

Dr. H. G. BAYNES (Zurich) sent a contribution with this title, which was read by Dr. BEDFORD PIERCE. The author said that in dementia præcox there was a certain toxic element, but the "complex" was the principal causative factor, and many psychotic cases had been cured by analysis. Professor Jung had told him of cure of cases seven years ago by this method, and there had been no relapse in the meantime. The right attitude to take in respect to these conditions was, "Is this condition due to some trauma or lesion producing a secondary disturbance, or is it a disturbance of function producing corresponding changes of anatomical structure?" This brought the greater responsibility of inquiring as to what was the primary cause of the disturbance in function; it brought one into contact with the individual moral problem. Clinical medicine could not be an exact science because it assumed man to be a constant factor. He referred to the derisive condemnation with which the medical world had treated the attempts of Freud and Jung to examine psychical disorders from the subjective and individual standpoint. He pointed out the respects in which Jung was unable to accompany Freud all the way, and quoted that authority's explanation of the unwillingness of the patient to forsake the pleasant world of his phantasy for the actual world of experience. The subjective comprehension of the psychotic state entailed upon the analyst a constant exercise of deep and sympathetic accord instead of that of the detached observer, so that he was able to enter the patient's unreal world with him. There was no essential difference between the phantasy-world of the insane and the dream-world of the normal person.

Criticism of Present-day Psychoanalysis.

Dr. WILLIAM BROWN contributed some criticisms of present-day psychoanalysis. He agreed there was in the profession a widespread lack of understanding of psychoanalysis, and this was well exemplified in the recent Cambridge meeting of the British Medical Association. Remarks were there made concerning it which those who understood the process knew to be

both untrue and unfair. Since 1912 he had endeavoured to test the various facts and theories which Freud and Jung had put forward. He had tried to analyse his own dreams, and had submitted himself to analysis, and he had been surprised at the way in which unconscious trends of thought sprang to the surface. He did not agree with Freud that everyone found life tremendously hard; a healthy man with a clean ancestry did not find it so. He agreed with Hughlings Jackson that the more one studied one's dreams the better would one understand psychology; but that did not mean that the normal waking life must be regarded as an outgrowth, a something superposed upon dreamlike activities. As early as 1892 Freud showed that when certain hysterical patients brought up lost memories an emotion was aroused which, having been worked off, left the patient much better; it was termed the method of "abreaction." Two groups of hysteria were determined on: retention hysteria and defence hysteria. Bryer, who went far with Freud, parted company from him on the degree to which he drew upon sex as a causative factor in these conditions, and it was at this parting that psychoanalysis was born. He gave some experiences in the cure of loss of memory and other mental symptoms by analysis during the war. Complete cure was brought about by abreaction and psychocatharsis. An important matter was giving the patient an opportunity of working off the emotion of fear which he had not the opportunity of doing while he was in the line, where soldiers were more or less in a state of stupor. Freud stated that emotions could not be remembered, but Dr. Brown could not agree with that. He quoted cases in which obviously childish emotions were lived over again in military patients. The chief difference between Freud and Bryer was on the libido content: Freud's view was getting nearer and nearer to the physical, while Bryer's was emotional. He (the speaker) thought psychoanalysis should be carried out as far as possible and as fully as possible. He believed that even in psychoanalysis where the examiner refrained from leading the patient on by his own remarks, the influence of suggestion, though unconscious, was present and potent. Sex tendencies, sadism, masochism were present in some cases, but he (the speaker) denied them anything like the universality claimed by Freud's disciples.

Discussion.

Sir ROBERT ARMSTRONG-JONES declared his belief that Freudism was dead in England to-day. When that system first came to light he regarded it as probably applicable to life on the Austrian and German frontiers, but not to virile, sport-loving, open-air people like the British. Psychoanalysis was thought to be a splendid thing because it brought baser desires to the surface and enabled them to be discussed; but he reminded the meeting that all the courtesies and conventions of decent society were founded on intelligent repression. These restraints were rather ridiculed by the new psychiatrists. He believed suggestion played a large part in psychoanalysis. The method was claimed as the thing for the educationalist, for spiritual development, for social welfare and social regeneration; he was astounded at the variety of the claims, which had not yet been substantiated. He proceeded to discuss the regional anatomy of the brain, the use of terms, and the mechanism of psychic determinism.

Professor GEORGE ROBERTSON, speaking as an asylum physician, insisted on the great distinction between a true, manifest psychosis and a psychoneurosis, though the two might coalesce in the same person. The importance arose as to the applicability of psychoanalysis, for to psychoneuroses psychotherapeutic treatment—such as psychoanalysis—was very suitable, while it was not at all beneficial to true psychoses, the subject of which could not be convinced that he had an abnormal mind; he regarded such an idea as nonsense. Professor Robertson also emphasised the fact that these early cases of psychoneurosis were not early cases of insanity, and did not tend to pass into insanity. He went on to discuss toxæmias and dream-states, and in regard to Freudism said that anyone who studied Freud on dreams and tried to analyse his own dream-states could not fail to be convinced of the truth of

Freud's contentions. He referred to a number of very instructive cases in support of his views.

Dr. BEDFORD PIERCE dwelt upon the view that because a thought or tendency was repressed it was bound to appear in some other way in the person; he thought the mistake made was in regarding them necessarily as realities, as comparable to water, which if pushed out of one place would come up in another. He did not think mental processes should be so considered; why should they not rather be considered as mental gunpowder? Gunpowder could remain unexploded for all time.

Dr. F. H. EDWARDS suggested that some synthetic process must follow the analytical, and asked why dreams were always symbolic. He did not believe early emotions could be revived, but only the memory of them, sometimes with a resumption of childish speech.

Dr. R. G. M. LADELL agreed that on first becoming acquainted with Freudism it seemed repulsive, but on proceeding to study it and on submitting oneself to analysis one was forced to the conclusion that Freud was justified in his contention that these tendencies did exist. Children were admittedly innocent, and that was the reason they were "indecent"; the indecencies of childhood were natural. Hypnotism was helpful in many cases of neurosis, but in others it was necessary to proceed much further and do psychoanalysis. He preferred to treat each case on its individual merits. He had been dealing with war cases in a pensions hospital, and some cases could be dealt with by clearing up the amnesia for the war period, or by suggestion in either the hypnotic or the waking state. But there persisted afterwards a state which did not justify turning the man loose upon the world to earn his living.

Dr. E. S. PASMORE did not think cases of dementia præcox were cured, and he referred to Sir Frederick Mott's contribution at the Cambridge meeting of the British Medical Association, in which he set out his pathological findings in 30 cases of dementia præcox, showing that the brain and body generally were badly developed. Cases alleged to be cured by psychoanalysts could not have been dementia præcox.

Dr. HELEN BOYLE (Brighton) said the great difficulty was that those most interested in the psychoses did not see cases until they were far advanced. The type of patients she had were those not sufficiently bad to be certified, but requiring treatment. They were mostly cases of psychoneuroses, with a fair sprinkling of cases of psychoses. It must not be forgotten that nearly every disease represented Nature's effort to cure something which did not harmonise with surroundings. Those who rushed in to cure mental diseases might conceivably make them worse; that had been the case repeatedly with physical disease.

The PRESIDENT read a letter from Professor Friedlander (Freiburg) in which he said that Freud was the father of pan-sexualism, and gave the names of many authorities in America and on the continent who rejected it. He contended that Freud's doctrines stood and fell with his interpretations of dreams, and that his proofs were not scientific and convincing. He felt it was wrong to attribute to every neurosis a sexual cause.

The PRESIDENT said it was the glory of the Claybury school that they showed the mechanical basis of all these higher associations, led by Mott, J. S. Bolton, and G. A. Watson, who proved that the supragranular layers of the cortex gradually developed from the earlier undifferentiated infragranular layers. He, the speaker, had tried to show they were mainly the places in which the instincts and ancestral memories were stored. In old persons, in whom, as Mott showed, the lipoids of the testicle were greatly diminished, there was a corresponding want of association, a fading away of the newer associations, and a retrograde return to the dominance of the infragranular layers. Why should so-called sexual exhibitionism be called bestial? It was the judgment of the associational layers of the cortex which had introduced that idea of indecency. It was necessary to throw oneself back into the innocent condition of the child before one could properly discuss these matters.

Reviews and Notices of Books.

VENEREAL DISEASES.

Their Clinical Aspect and Treatment. By J. E. R. McDONAGH, F.R.C.S. London: William Heinemann. 1920. With an Atlas of 106 colour and 21 half-tone illustrations. Pp. 419. £3 3s. net.

THIS book is full of interesting observations collected from a vast amount of clinical material. Throughout the work the author emphasises the importance of careful clinical observation as opposed to pathological examination. Not only can a syphilitic chancre be distinguished from a non-syphilitic one by clinical examination, but some idea of the probable course of the disease may be gleaned from the appearance of a syphilitic chancre. Mr. McDonagh admits that such a laboratory investigation as the examination of a lesion for spirochaetes is of value. It is, however, a subsidiary means of diagnosis, and must always be regarded as of secondary importance to the clinical examination.

The author shows a similar suspicion of laboratory methods in deciding when a patient is free from gonorrhœa. He is of the opinion that an elaborate search for gonococci in the urethra or prostate of the candidate for marriage is useless.

"In revising this chapter, after four years, I am even more emphatic on the point that a pathological report is practically useless, and that a clinical opinion is the only reliable means upon which to base an advice on marriage."

The clinical tests for fitness to marry consist of a careful overhauling of the urethra and prostate, with special attention directed to dilatability of the former. If dilatability by means of a Kollman is below normal "the chances are that there are gonococci hidden in the follicles or in the subepithelial tissue." Dilatation will probably wake them up, and a big injection of a potent non-sensitised vaccine will also help to do this. If the dilatability is normal, and if a vaccine does not alter the status quo, the patient may be passed as a fit candidate for marriage. However, it is in the section of the book devoted to the subject of syphilis that the chief interest lies. Mr. McDonagh's views concerning the pathology of syphilis are already well known. In the work under review the clinical rather than the pathological aspect of the subject is considered, although the author does not lose the opportunity of bringing forward points in favour of a cycle in the life-history of the organism of syphilis.

Chapter XI. is devoted to the subject of syphilis of the nervous system. To such an extent is neurosyphilis on the increase that Mr. McDonagh believes that the day will arrive when syphilis will be considered, broadly speaking, a disease of the central nervous system. The best method of combating this increase is, of course, the earlier diagnosis and prompter treatment of the primary lesion. When syphilis has become generalised more prolonged treatment is required than is commonly employed. More attention should be paid to the intermittent treatment and less to the attainment of a negative Wassermann. Finally, in the author's opinion intramuscular injections of intramine are of great service in this connexion.

"Much nervous syphilis can be prevented by the routine use of intramine, which prevents arsenic and mercury from exercising a toxic influence on nerve tissue, thereby rendering it a locus minoris resistentie for the syphilitic organism. This is proved by the fact that I have seen only one neuro-recurrence occur in cases so treated since 1915."

Although the author has intended to confine himself to the clinical aspect of his subject he cannot resist the temptation to indulge in speculation on the pathology of disease and the action of the therapeutic agents employed in its treatment. It is here that the weakness of the work lies. Mr. McDonagh has imagination, a gift that is as valuable to the scientific as it is to other kinds of writers. But the scientific writer with imagination must ever keep in mind the foundation on which he builds. Upon a given base a certain amount of superstructure may be erected. However plausible the theory, the fact that it is a theory must never be lost sight of. Mr. McDonagh is generally ingenious, but he

is frequently unconvincing. He builds on precarious foundations. He is frequently illogical.

The book is beautifully and lavishly illustrated. The coloured plates are, indeed, exceptionally good. Whilst Mr. McDonagh's work is full of points upon which a hostile critic might dispute, it is full of interest. Amongst the colourless works on venereal disease which are appearing almost weekly, it stands out conspicuous for its originality. Many will strongly disagree with the views it contains, but few will deny that it is suggestive and stimulating.

ESSENTIALS OF TROPICAL MEDICINE.

By WALTER E. MASTERS, M.D., M.R.C.S., L.R.C.P.
London: John Bale, Sons, and Danielsson, Ltd.
1920. With index. Pp. 702. £2 2s.

THE preface says that this work contains nothing new, and is not intended to act as substitute for any other work. Its aim is to furnish a digest of tropical medicine in a form handy for ready reference—a vademecum, in short, for the student and busy general practitioner. That there is a use for such a work is evident, if we consider how tropical medicine has expanded and how much zoology is now included under the term. As a result the standard books have become somewhat bulky and unwieldy, and the necessity of a digest of them is rendered real, especially for those who cannot follow new papers in the different journals. Dr. Masters attempts this ideal and has succeeded, on the whole, very well, although the book, with its appendices and index, runs to 702 pages. A book of "Essentials" should be free from error, but this is unfortunately not quite the case here. On p. 42 the statement is made that amebic dysentery frequently attacks the small intestine, while of bacillary it is said that it is nearly always confined to the large, whereas it is just the other way about, and such a statement may lead to grave misunderstanding or even to a student failing in an examination. Again, on p. 29 no mention is made of *S. mansoni* dysentery nor of heterophyes enteritis. But these are points which can be remedied in a subsequent edition. The book contains valuable information and will serve a useful purpose.

LE CŒUR ET L'AORTE.

Études de Radiologie Clinique. Troisième édition.
By H. VAQUEZ and E. BORDET. Paris: J. B. Baillière et Fils. 1920. Pp. 259. Fr. 20.

THE third edition of this well-known monograph contains a good deal of new matter. The early chapters contain an excellent description of technique. The authors are well known for their warm advocacy of the orthodiagraphic method. Using this as a routine plan, they have arrived at a multitude of diagnostic conclusions, of which this general criticism may be offered, that their clinical judgments do not seem to have been adequately checked by post-mortem data. To those for whom skiagraphy of the heart and aorta means no more than a search for aneurysms, it will be instructive to remark that less than one-twelfth part of the book concerns itself with the aneurysmal shadow. The interesting chapter on pericardial lesions includes no remark on the skiagraphic appearances of pneumo-pericardium, but we have noted no other serious omission. The book is the handiwork of two enthusiasts, and gives the fullest account of the subject yet published.

OPHTHALMOLOGY.

For Students and Practitioners. By A. BRÜCKNER and W. MEISNER. Leipzig: G. Thieme. 1920. With 126 figures and 1 coloured plate. Pp. 650.

THIS is a business-like and efficient account of the subject written by two chief assistants of Professor Kruckmann of Berlin. The whole subject is covered, and though the illustrations are limited in number on account of expense, they appear to be well chosen and clear. The authors express the fear that many students in Germany will not be able to afford to purchase one of the larger works, and offer this one as containing all the essential matter to be found in them, while omitting what is non-essential. On the whole, they have

performed their task well. Here and there they are not quite up-to-date. Donders's chart of the relation between age and presbyopia has been shown to give more nearly the minimum than the average accommodation at different ages. Again, senile macular degeneration is well described, but there is no mention of the similar condition which is sometimes found in early life in more than one member of the same family, and may be associated with mental defect.

THE MENTAL HYGIENE OF CHILDHOOD.

By Dr. WM. WHITE. London: Heinemann and Co. 1919. Pp. 194. 6s.

THIS is a careful psychological analysis of the development of the child mind from infancy to adolescence, written primarily for parents and teachers. It is distinctly Freudian, and the parent must not become alarmed when he reads that much of the infant's activities, such, for instance, as his unconcern at showing himself naked, are of a sexual character; he will find statements much more startling as he proceeds. Dr. White, to a large extent, discounts heredity as a factor, maintaining that the child's environment during the first five years of life is of much greater importance in the formation of character and tendencies, and many will agree with him. He maintains that hereditary tendencies may be modified, or diverted into other channels when the child is young. He is convinced that our present educational methods tend to sacrifice the individual to the formal scheme. There is an interesting chapter on the function of parents, and the book will undoubtedly be widely read in the American home.

JOURNALS.

British Journal of Tuberculosis.—The July number contains a generous tribute to the life and work of Sir William Osler by Dr. S. Adolphus Knopf.—Dr. H. Batty Shaw, dealing with the distinction between pure pulmonary tuberculosis and the compound disease known as consumption, stresses the importance of secondary infections, and suggests that if these can be eliminated the course of pure pulmonary disease would be fibrotic and benign.—Dr. John Craig-MacGown writes about muscular changes in pulmonary tuberculosis, and Dr. W. Gordon shows how his studies in the relation of rain-bearing winds to pulmonary tuberculosis are illuminated and corroborated by Dr. Brownlee's researches into the epidemiology of phthisis.—Dr. W. A. Muir discusses the value of v. Pirquet's test, and Dr. E. Gladstone Davies gives an account of the tuberculosis campaign of the American Red Cross in France.

American Review of Tuberculosis. Baltimore: National Association for the Study and Prevention of Tuberculosis. 50 cents.—The June number begins with a paper by Dr. Arthur L. Bloomfield, in which he describes certain experiments dealing with the growth of bacteria in the upper air-passages. He finds these passages unfavourable to the growth of various bacteria, and he suggests that some preliminary injury may possibly be essential to the initiation of such diseases as pneumonia and tuberculosis. Discussing 24 years' experience with the subcutaneous tuberculin test, Dr. Lawrason Brown and Dr. Fred H. Heise note that this test has gradually fallen into disuse. One of the authors has had two or three severe reactions (104°) to tuberculin, a spray of which was inhaled. They used Koch's old tuberculin (O.T.), and are convinced that, if the test is carried out carefully "..... the evidence is overwhelmingly in favour of no permanent harm being done." Their material consists of 324 patients, 42 of whom failed to react to a second dose of 0.01 c.cm. O.T. (10 mg.). It is interesting to note that none of these 42 is known to have died of pulmonary tuberculosis. The authors confirm the current view that the significance of a negative test is much greater than that of a positive test. Dr. Martin F. Sloan contributes to the already prodigious output of papers concerned with the relation of influenza to pulmonary tuberculosis. He refers to 29 representative and widely scattered sanatoriums which admitted 7871 patients, 15 per cent. of whom traced the onset of tuberculosis to an attack of influenza. Dr. H. J. Corper and Dr. H. Gauss describe experiments showing that the effect of heat and venesection on tuberculous guinea-pigs is negligible.—In a paper on Work for the Tuberculous, Dr. David A. Stewart discusses, with considerable impartiality, the burning question of colonies, and he diplomatically remarks that what may be very suitable in England may be "entirely unworkable" in Western Canada.—The final paper, on the Influence of Climate on Pulmonary Tuberculosis, by Dr. John W. Flinn, adds nothing new to a very old problem.

THE LANCET.

LONDON: SATURDAY, AUGUST 21, 1920.

Hysteria as Purposive Inattention.

IN his Croonian lectures delivered before the Royal College of Physicians of London, and published in recent issues of THE LANCET, Dr. ARTHUR F. HURST, through whose hands at the Seale Hayne Hospital there passed during the later years of the war an immense number of functional cases of all sorts and conditions, has outlined in some detail his views on the essential nature of hysteria, citing in support many examples of hysterical disorder which have yielded to his treatment. The lectures deal mainly with hysterical disturbances of the special senses and of cutaneous sensibility, although much else of interest therewith is incidentally touched on. Dr. HURST is apparently an adherent of the pithiatric school of BABINSKI, whom he follows in asserting that "hysteria is a condition in which symptoms are present which have resulted from suggestion and are curable by psychotherapy." At the same time he avoids the difficulties inevitably encountered in any too rigid limitation of this criterion by accepting and, for that matter, corroborating and extending by exact observations of his own, the view that hysteria may and can alter cutaneous, vasomotor, and other reflexes; his explanation of the production of such departures from the normal, however, has little to do with any action of suggestion in the strict sense of the word. Dr. HURST is of those who reject altogether the specificity of hysteria as a morbid entity; if the suggestion is powerful enough "there are probably no individuals who would not develop hysterical symptoms"; abnormal suggestibility is a predisposing but not an essential factor. By this simplification the vexed questions of what constitutes abnormal suggestibility, what is the state of mind allowing it, which suggestions are responded to and which repelled, whether those accepted have significance in connexion with the previous experiences and unconscious desires of the individual concerned—such questions of psychological import are ignored. Anyone will develop hysteria if the provocation is sufficiently great; otherwise expressed, the hysterical mind has no characteristics distinguishing it from the normal mind.

Although, as far as we have noticed, Dr. HURST does not actually so express himself, it might seem that this view brings his position to some extent into line with the conception frequently expounded of recent years, that hysteria and the psychoneuroses generally are to be regarded as modes of reaction of the organism to its environment, a biological conception no less applicable in the psychical than in the physical sphere. Now if this hypothesis be adopted, it is clear that differences in the psychoneuroses can be only explained either by differences in the individual organisms or in the stimuli brought to bear on them.

If we are all potential hysterics in the face of sufficient provocation, then groups of fighting men—to take an illustration from the material mainly utilised by Dr. HURST—undergoing precisely the same powerful and simultaneously acting stimuli should all have developed hysteria if any one did. A view, needless to say, at variance with known facts. Moreover, not a few men "broke down" within 24 hours' experience of the firing-line, and others before they ever crossed the Channel. Evidently the excitants in such cases were of minor intensity in comparison with what others were at first able successfully to resist, and the conclusion is, indeed, unavoidable that hysteria is in reality a pathological state appearing in certain individuals only who fail to withstand the provocation of their environment because of some inherent or acquired psychical defect. It becomes a matter of surpassing importance to endeavour to determine wherein the imperfect reaction takes its rise, and why suggestion acts in some cases and not in others; and any analysis of the psychological material at his disposal would have enhanced the value of Dr. HURST's contribution to one of the serious problems of the time.

The major part of the lectures is occupied with a consideration of the mechanism of production of hysterical symptoms, not in the sense of the effect of emotional conflict and tension and its exteriorisation in symptoms, for little or nothing is said of this view of their pathogenesis, but rather along the familiar lines laid down by JANET, that hysteria is a form of amnesia or "absent-mindedness." Dr. HURST adopts eclectically what the French professor admirably demonstrated long ago, that the hysteric does not "attend"; he looks obliquely or askance at things; certain elementary phenomena, sensations and images, cease to be perceived and appear suppressed; there is a lack of psychical synthesis. The student of hysteria knows well the importance of JANET's work in the development of our modern conceptions of the subject, and he realises the significance of the latter's emphasis on the remarkable fact that the anaesthesia and amnesia of the hysteric are often systematised; in other words, the patient is anaesthetic and amnesic for certain stimuli only, or at certain times only, or in certain circumstances. It was left to the genius of FREUD to make the conception far more complete by his study of the question *why* certain systems of ideas should split off from personal consciousness and *why* the hysteric should cease to attend to certain excitations. With these psychological matters Dr. HURST is not concerned; but, assigning a causative rôle to the inattention, which is a symptom, he makes the speculation that "the structural basis of the psychological act of attention consists in some change which leads to a diminution in the resistance offered at each synapse of the sensory tract." The hysterical patient is deaf because he does not attend to sounds, and because he does not attend he does not hear, the suggestion being that inattention consists physiologically in a "throwing out of dendrites, or in some biochemical change in the material which occupies the space between the dendritic terminations of adjacent neurones." It should be remarked that Dr. HURST uses the term attention in a sense which makes it difficult to distinguish from a mere physiological process; "this active attention is as little a conscious process as the performance of the individual movements in walking." Apart from the essentially speculative basis of any theory

of dendritic action, and from the fact that the inattention itself requires to be explained, it must be pointed out that the difficulty in this view of the production of hysterical phenomena is its failure to account for the systematised nature of many hysterical symptoms. We know that the hysterically blind, or deaf, or anæsthetic do, in fact, see, and hear, and feel, as can often enough be readily demonstrated; certain stimuli are perceived, but others do not appear to be, and analysis will reveal an actual psychological explanation of this condition of purposive inattention. There can scarcely be a physiological impairment in peripheral synaptic action when stimuli are, in fact, perceived, though some are not apperceived; and it seems immaterial to seek a physiological theory of dendritic oscillation for acceptance or inhibition of sensations when the clue can be readily found in the psychological sphere.

Discussion of this matter, none the less, has a wider bearing than might appear. If we suppose some of the somatic and visceral phenomena of hysteria to be the outward expression of disintegrative action of neuronal systems, as nervous health is of an integrative action—a view which has been suggested by OPPENHEIM, BINSWANGER, and others—we may ask to what level temporary functional disintegration can on occasion extend; and much of Dr. HURST's investigation of somatic symptoms can be profitably utilised in consideration of the question. He has adduced evidence which goes to show that the function of mesencephalo-spinal reflex arcs can be put in abeyance in the course of hysteria, indicating that the neuronal disintegration may extend far below transcortical paths if the condition is profound enough. The psychologist may ignore the neuraxis and its function when he has found the cause of a patient's hysteria in an emotional conflict, but the neurologist is legitimately interested in explaining the absence of the plantar reflexes, or even, if Dr. HURST's statement be accepted, of the pupillary reflex to light.

Medicine and Aeronautics.

THE practical part to be played by medicine in the development of aeronautics was more than suggested at the recent Aeronautical Exhibition, where a gallery was set apart for the use of the Air Ministry. The Medical Section was divided into three subsections. In the first were demonstrated the apparatus and material which medical officers had helped to design for the general welfare of the pilot. In the second subsection the apparatus used by medical officers during their researches into the question of physical efficiency and flying ability were set out; while in the third a model room as used for the examination of the civil pilot of to-day was shown. These several subsections demonstrated not only the influence of medical research directed towards aeronautics in other and general medical fields, but they also proved the advantages and possibilities of team-work between those engaged in progressive medical work and men of science working upon other lines or specialising in other professions. The exhibition as a whole, with its promise of rapid future transport, conveyed the uncomfortable message that the spread of communicable diseases might be considerably accelerated, and this is a matter which will require watching, but is not under discussion here.

The influence on general medicine of work in the first instance devised for aeronautic purposes was well exemplified by an exhibit of the apparatus employed for the administration of oxygen to flying men. One type of this apparatus, which was shown in its various stages of development and design, as well as in its perfected form, has since become the standard apparatus for use in many of our hospitals. Now that it has been seen and tried, it becomes surprising that the unscientific and wasteful method of giving oxygen to patients by means of a glass funnel attached to an oxygen cylinder, without any graduated regulating tap or proper reduction valve, was not abolished long ago in favour of proper regulating appliances and a suitable mask. So the need of the airman has benefited the whole of practical surgery, and suitable types of oxygen apparatus can now be purchased for use at the bedside, in which the actual quantity of gas supplied per minute to a face-mask worn by the patient can be accurately gauged. Another piece of apparatus shown in the Medical Section may also eventually prove to be of value for other than air medical problems. This is the gas-mixing apparatus designed by Professor GEORGES DREYER in collaboration with Mr. G. F. HANSON, an American worker on problems of physical efficiency. This apparatus is primarily designed to estimate the ability of individuals to withstand great altitudes by the gradual addition of nitrogen to the air breathed, thus reducing the percentage of oxygen. It is so constructed that it can supply any two gases, or any two liquids, in constant volume in any proportion required, accurately and steadily. The adaptation of this principle to the administration of anæsthetics should prove useful—here is a line along which our anæsthetists might work; while in trades where liquids or gases have to be mixed in definite proportions its scope of utility is obvious. It has, for instance, been shown that it is possible to maintain the exact proportions of air and petrol vapour required for the most efficient explosion, so that neither waste nor starvation need occur. With petrol at its present price the economy that should result is not negligible. In the direction of clothing and personal equipment, practical lessons have also been learned from the medicine of the air which can be applied to the medicine of the home or the institution. Electrically heated clothing, special goggles, safety belts and helmets, have been devised, and the practical use is thus demonstrated to which physiology and anatomy can be put when applied in close collaboration with non-medical experts. The extension of this field of coöperation is bound to bring good results, for in this way the medical man is brought into closer and more personal touch with working conditions, while trained and scientific technicians will have a better chance of placing a knowledge of psychology at the disposal of industry.

We trust that many of our readers saw the exhibition of a model room as arranged for the examination of pilots; it contained within its walls a summary of much that was instructive and interesting in regard to many difficult questions of physical efficiency. The examination of pilots has now become a question of distinguishing differences among those who would always be passed as first-class lives by an insurance office. It has been found that only those who can meet satisfactorily the necessary tests of insurance examination can withstand the stress of air work, and it has been assumed that this class can resist

infection generally better than others. But the strain of air work must be looked upon as a concentration of the strains of ordinary life, and first-class lives among non-flying individuals, though falling into the highest categories of physical efficiency are not asked to bear this concentration, apart from the question of special risk. It is not, in a scientifically ideal condition of things, sufficient for the airman to be what is called by the insurance office a first-class life; we must try to subdivide the first-class lives and to ascertain which of the individuals possessing this happy standard can satisfy the accurate application and interpretation of the special tests elaborated for the selection of pilots. Just as the object of all modern medicine is to ascertain the symptoms of disease in its earliest stages, so the examination of pilots attempts to ascertain not only the proofs of physical stamina but the earliest signs of impending physical inefficiency. With what measure of success can be gauged by the pre-eminence of our pilots in the war. It is largely due to the special work of Wing Commander MARTIN FLACK and Professor DREYER that it is now possible to estimate, and record accurately, minor signs of physical inefficiency long before gross lesions make their appearance. Progress on the road towards the absolute measurement of physical fitness may be said to have commenced satisfactorily, and here again the medicine of the air may be vitalising the medicine of civil life. The practical utilisation of the tests devised for air men by insurance companies should become a matter of importance, as it is clear that if by means of a few simple measurements individuals can be graded within the general category of those physically efficient, we have a means of reducing the premiums asked in the case of those falling within the higher categories. Medical examiners may be able to "sense" disease before it makes its appearance, the measurements employed being in their turn direct inducements to the maintenance of physical health among the candidates for insurance. Insurance companies often grant a reduced premium to teetotallers, and it should be possible to arrange that insured lives when particularly physically fit should reap similar advantage at the time of insurance, and they might even gain further advantages of reduction of premiums if they were prepared to submit themselves to special tests of this nature from time to time. Work is being constantly carried out by the medical department of the air force in the endeavour to add new methods of accurately measuring the degree of efficiency of the various systems. The possibility of utilising such special war work as air medical work for the general benefit of industry and preventive medicine must never be forgotten.

Your Telephone Number.

WHEN is an advertisement not an advertisement? Medical men resident within the London telephone exchange system have during the past week received a circular letter from a business firm detailing an agreement made with the Postmaster-General which has a bearing upon their convenience, although they have not been consulted. This agreement is to supply free of cost to every London telephone subscriber a copy of a classified directory of trades and professions, including the profession

of medicine. Four specimens of the type to be used for this supplement are given in the circular; these increase in magnificence from ordinary breviter to bold pica, the cost of the insertion varying in accordance therewith from one to four guineas. No indication is afforded to the medical man of the appropriateness of the type which he should select. In the examples given members of the London Stock Exchange are suggested as requiring a one-guinea insertion, solicitors a two-guinea, printers a three-guinea, and engineers a four-guinea insertion. The naïve note is appended that professional entries in this publication are not advertisements. Whether they are advertisements or not may well be left to the decision of a less interested tribunal, but it is difficult to see what the inserter is asked to pay guineas for if it is not to make himself better known. In the meantime, we should like to know to what extent classification is being carried out, and whether doctors are to be scheduled in this publication under specialist subheadings. This, at all events, the medical profession is entitled to have some say in. In any case, we fear that a list issued along with an official postal document may convey the impression to unwary telephone subscribers that only the names included in the directory are those of authorised medical practitioners. If the classified directory is to contain medical names at all it is in fact putting pressure on doctors to advertise in it (we use the word advisedly) at one to four guineas a head. As far as medical men are concerned the telephone directory as it stands serves its purpose quite well, which is simply to enable the patient to communicate with his doctor. And what more is wanted? The Medical Directory provides a reference book of professional attainment such as is held to be proper and convenient by the medical profession as a whole. We hope that London medical men will not waste a guinea on what may put them in rather an invidious position.

The Proposed International Health Office of the League of Nations.

IN our issue of April 24th last we referred somewhat fully to the proposals made by the International Conference of Public Health Experts, held at the Ministry of Health in London in April, at the request of the League of Nations, to advise on the steps which should be taken to provide the League with a suitable organisation for dealing with international health questions. The London conference, it will be remembered, made a series of detailed recommendations regarding the functions and duties of the proposed organisation, the incorporation within it of the existing Office International d'Hygiène Publique established under the Rome Convention of 1907, and the nature of the permanent machinery which the new International Health Office would require. An important further step in this direction was announced at the conclusion of the recent meeting of the Council of the League of Nations at San Sebastian. The Council have now adopted the scheme prepared in London, with a few minor amendments, and have unanimously recommended it for formal adoption by all the nations in the League at the General Assembly which will be held in Geneva in November.

Annotations.

"Ne quid nimis."

THE POSITION OF THE MEDICAL PROFESSION IN VIENNA.

THE special article on Economic Conditions in Vienna, which appears in another part of this issue, pictures the fate of the middle-class in general. The medical profession is involved in the common ruin. The doctor's expenses have risen quite out of proportion to the fees which it is possible for him to charge. The maximum consulting fee in Vienna at the present time is 100 kr., with a purchasing value, expressed in English money, of about 3s. 2d. With so many members of their own social class in dire poverty, not a few Viennese doctors are doing their professional work for nothing. But the cost of drugs and medical appliances has, of course, risen just like other things. Those who are intimately acquainted with the work of the medical profession in Vienna testify that it has been maintained as yet at a very high standard. All that the doctors can do they have done. In spite of low salaries, public health work in all its branches, the prevention of epidemics, and the care of infant life are first-rate. As a matter of fact, the infant mortality did not rise in spite of the terribly high general death-rate, a result which may fairly be ascribed largely to the organisation of infant welfare centres, rapidly extended during the war in the face of economic difficulties. The campaign against tuberculosis has gone steadily forward in the dispensaries, sadly hampered, it is true, by the impossibility of increasing sanatorium accommodation; and although the widespread malnutrition has made some increase in the tuberculosis mortality inevitable—the rate has increased from 30 to 58 per 10,000—it is a surprise to those who best know the local conditions that this increase is not still greater. Here the result is much to the credit of the tuberculosis dispensary staff.

Medical practitioners in more fortunate circumstances might stop to think what it means to colleagues, who know the possibilities of modern medicine and who are accustomed to give their patients the benefit of recent discoveries, to be forced to return to the weapons of previous generations—often, indeed, without even their modest equipment. The restriction of anaesthetics and of dressings for operations, and the total lack of clean linen for the patients make appeal to the non-medical mind, and relief funds have been available to some extent to remedy the needs, but doctors alone can realise what it is to do without important drugs, the essential parts of X ray and other complicated apparatus, stains for bacteriological work, animals for inoculation and serum preparations, and a thousand other things to which a committee, charged with the care of half-starved children, can hardly apply their scanty funds. English and American doctors now helping in Vienna see how painful is the lot of their colleagues obliged deliberately to lower the standard of their work in a city of magnificent institutions with appliances out of order for want of some comparative trifle. Nor is it less hard to see patients die for want of treatment which a little money could get them, even if it be remembered that 50 years ago there would have been no alternative to death. Isolation from scientific workers in other countries is also keenly felt by the medical profession in Vienna. They cannot afford to buy books or medical papers from other countries, and still less can they afford, even should passport facilities be available, to travel abroad. Medical visitors are warmly welcomed in Vienna that they may apply their experiences of work done in England during the war period.

Individual help given to a starving city may seem like a drop in a bucket, but there is no reason to doubt that an organised scheme on the part of the medical profession at home to help their Vienna colleagues would meet with tangible results. A beginning has already been made through an influential

University Relief Committee and through special committees for practitioners not connected with the University. The Friends' Relief Mission now working in Vienna, of which Dr. Hilda Clark is organising secretary, can arrange for any help that is forthcoming to be given to the medical school, both staff and students, or to doctors in general practice. Clothing is especially needed, and those who have no money to spare can give old garments, which the Viennese are clever at re-making. Gifts in kind meet with ready acceptance.

DR. MARCEL BLOCH ON COAGULATION.

IN the course of an article which appeared in our French Supplement on August 7th Dr. Marcel Bloch dealt with the measurement of the coagulability of the blood and with the clinical conditions under which the blood coagulates less readily, putting forward in so doing a new and interesting view of the relation of calcium to coagulation. It has long been known that, in order to bring about the formation of thrombin, calcium must be present in ionic form, and that citrates render blood incoagulable by uniting with calcium to form a non-ionised, though still dissolved, compound. Dr. Bloch suggests that in the circulating blood calcium is present in a non-ionised or, as he prefers to call it, an inactive form, and that, when blood is shed, external processes bring about the conversion of inactive to ionised calcium, and so permit coagulation to occur. The external processes include contact with foreign surfaces and the setting free of kinase. If we understand him rightly, Dr. Bloch further believes that delayed or imperfect activation (ionisation) of calcium, when blood is shed, may be responsible for the lessened coagulability of the blood in hæmophilia and other clinical conditions.

Although Dr. Bloch does not himself bring forward any evidence in support of this theory, there is reason to believe that some calcium is present in the blood in combination with protein; and, since such compounds are very slightly ionised, the calcium thus combined would be almost entirely inactive as regards the process of coagulation. But the presence of inorganic calcium salts in the urine points very strongly to the existence of such salts, presumably chloride or phosphate of calcium, in the circulating blood plasma. If this is the case, calcium will undoubtedly be present in its ionic form in the circulating blood. It is clear, therefore, that there are difficulties in the way of accepting Dr. Bloch's suggestion, and that direct investigation of the form in which calcium exists in the circulating blood is desirable in order to substantiate this view.

The surgical interest of Dr. Bloch's paper lies in the bearing which his investigations may have upon the use of sodium citrate in blood transfusion. The clearer our conception is of the precise manner of action of the sodium citrate in preventing coagulation the more satisfactory is the use of citrated blood in hæmorrhage, shock, and blood diseases likely to become. It is at present not entirely so because sodium citrate is undoubtedly toxic, the degree of toxicity varying according to the idiosyncrasy of the patient. It is desirable therefore to use the minimum amount of sodium citrate compatible with its efficient action, and to arrive at this it is necessary to have a precise knowledge of the nature of the reaction that is taking place. It may even be useful to apply Dr. Bloch's method of measuring coagulation indices to the blood of a particular donor in order to determine the precise quantity of anticoagulant that may be necessary to prevent the clotting of his blood; not, of course, in an emergency, but in ordinary therapeutic blood transfusions. It is hampering to the surgeon to lack the means of inactivating the calcium electrolyte in the circulating fluid when this, through some obscure cause, has become abnormally active. Sodium citrate does not have this action in the circulation because it is rapidly destroyed; it has even been stated that injection of sodium citrate into the circulation increases the coagulability of the blood. A patient died recently in St. Bartholomew's Hospital from a pulmonary

embolism, some time after having been admitted for injuries received in a fall from a window. There was a superficial wound on the outer side of the right leg, but this had healed by first intention, and no other injury or septic focus in the limb was discovered post mortem. Nevertheless, its main venous channels were found to be occupied by a blood clot extending from the foot to the common iliac vein. This can only be explained on the hypothesis of an altered coagulability of the blood produced by some unknown factor. The surgeon is in need of an accurate method of measuring coagulability, and Dr. Bloch's work may help him to get it.

WORKING OUTPUT AGAIN.

LAST week we noticed in an annotation an important contribution by Dr. H. M. Vernon on output in relation to altered hours of work. Those who are accustomed to think of the United States as ahead of us in industrial matters will be astonished to find that a report¹ just published is the first of a series to be issued under Government authority dealing with problems of industrial working capacity. In the States spade-work upon these problems has not been so extensive as might be expected. The present report, however, is a serious contribution to knowledge. It contains data collected, not by the useless questionnaire method, but by investigators, thus enabling the reader to check the conclusions. The information set out was gathered from two engineering factories employed one on an eight-hour day, the other on a ten-hour day. The onset of fatigue is studied from the hourly rise and fall of output in the two plants and from the hourly accident-rate. Labour turnover is compared under the two systems, and the effect of the experimental introduction of rest pauses. An interesting preliminary note upon a study of rhythm in industrial work is also included. The comparison is strongly in favour of the eight-hour system in every case. Unfortunately, the articles produced in the two factories were not similar, and difficulty faced the investigators in establishing a fair comparison. We do not feel confidence that the difficulty has been satisfactorily overcome. Thus, to permit of comparison, processes are grouped after inspection into dexterous handwork, muscular handwork, lathe machine-work, and miscellaneous machine-work; then the curves of output of the groups in the two plants are compared. This method presupposes correct grouping, one of the matters under investigation. A sounder procedure would have been to group the processes together of which the curves of output proved similar and then to examine the processes so grouped to see what common characteristics they possessed. The method adopted smacks of *a priori* reasoning. Our confidence in the conclusions drawn is especially strained when they are at variance with those drawn by other investigators; further, we may express regret that the work of Dr. Vernon is somewhat unnecessarily attacked. An instance may be given of a conclusion which does not appear to be justified by the data. Comparison is made in the ten-hour plant between the curves representing hourly output and hourly accident-rate. The two are not found to keep parallel; and the steeper rise of the accident-rate while the output is still rising is held to indicate the appearance of diminishing neuro-muscular coördination (claimed to be a sign of incipient fatigue) before output commences to fall. If this conclusion is correct, the definition of fatigue² as "the sum of the results of activity which show themselves in a diminished capacity for work" falls to the ground. Therefore this conclusion challenges attention, apart from the fact that Vernon's work is attacked on the strength of its correctness.

The report itself, however, provides evidence—not used for this purpose by the writers—that the curves of output and of accident-rates used are not really

comparable, from which it follows that the conclusion is not soundly based. This evidence we will explain. Output increases per worker with length of employment—even in the case of simple repetition processes some four months must elapse before it attains a reasonable level, and in complicated heavy processes some 12 months may be required;³ therefore, even if the personnel of a plant is evenly distributed according to length of employment, the output curve tends to represent the activity of those with longer employment rather than of those with shorter employment. But at the ten-hour plant 66 per cent. of the personnel had been employed more than six months, from which the conclusion follows that the output curve is mainly representative of the output of this 66 per cent. of the workers and not of the output of the remaining 34 per cent. of newer workers. The probability (which almost amounts to a certainty) is that the curve of output hour by hour of the 34 per cent. of workers with less than six months' experience, who for lack of skill and practice will be especially affected by industrial environment, would be entirely different, and that no deduction as to the activity of this 34 per cent. can be drawn from the general output curves. On the other hand, accidents are definitely stated to have been more prevalent during early weeks and months of employment than during later periods, "the level of the accident-rate varies inversely with the experience of the workers": 34·7 per cent. of all accidents are stated to have occurred during the first three months of employment, and 13·8 per cent. during the next three months—i.e., 48·5 per cent. of all accidents occurred among the 34 per cent. of workers in their first six months of employment. The accident curve then is composite, and represents about equally the tendency of accidents to occur hour by hour among those employed less than six months, and among those employed over six months, but does not represent accurately the tendency to accidents of either group. Clearly no sound deduction can be based on a comparison of these two curves; much less an attack upon the work of others.

Further, the disparity of the curves of accidents and output was found less striking in the case of the eight-hour plant, and this is ascribed in the report to the presence of less incipient fatigue due to shorter hours. But at the eight-hour plant the proportion of operatives with less than six months' experience may be fairly presumed to have been far less since the labour turnover, 30 per cent. per annum, was nearly six times lower than that, 176 per cent., on the ten-hour plant. Hence on the eight-hour plant the curves of accidents and output more nearly approach to being comparable factors, but whether sufficiently so to base conclusions upon cannot be determined from the data given. Notwithstanding these accidental occurrences, which must often appear when work is embarked upon in an unfamiliar field—they are like the tendency to accidents among those newly employed—we welcome this contribution to the study of the human machine, its activity and health, and look forward to the issue of later publications from the same source.

CONGRESS OF COMPARATIVE PATHOLOGY.

THE Second International Congress of Comparative Pathology will be held in Rome in April, 1921, under the distinguished presidency of Professor E. Perroncito, late director of the Royal School of Veterinary Medicine at Turin. A preliminary programme has been issued in which the secretary-general of the Congress announces that he is prepared to receive titles and abstracts of papers dealing with comparative pathology of man, animals, and plants, which should reach him before Dec. 15th, 1920. The Congress will be conducted on lines similar to those of the first Congress held in Paris in 1912; the fee for admission will be 40 lire, and arrangements are being made to secure reduced fares by land and sea to its members. Professor G. H. F. Nuttall (Longfield, Madingley-road, Cambridge) has been entrusted with the task of forming a committee

³ The Speed of Adaptation of Output to Altered Hours of Work. Industrial Fatigue Research Board, Report No. 6, 1920.

¹ Comparison of an Eight-hour Plant and a Ten-hour Plant. Public Health Bulletin No. 106, 1920. Government Printing Office, Washington. Pp. 213, 25 cents.

² Industrial Fatigue and Its Causes. Health of Munition Workers Committee. Memo. No. 7 (Cd. 8213), 1916.

in this country to further the work of the Congress, and, pending its formation, will be glad to receive communications and names of intending members. Among the subjects already proposed for discussion are influenza in man and animals, foot-and-mouth disease, cancer, hydrophobia, diseases of cattle, poultry, and bees, various parasitic diseases, and nerve regeneration. Further suggestions will be welcomed if sent to Professor Nuttall or direct to the Secretary-General, Professor Mario Levi Della Vida at 58 Via Palermo, Rome.

PELLAGRA AT PORT SAID.

INFORMATION goes on accumulating bearing on the ætiology of pellagra in the Near East. In a report recently issued Dr. R. G. White, deputy director of the Public Health Laboratories, Cairo, states that on Sept. 13th and 14th, 1915, there arrived at Port Said 4058 Armenian refugees from the neighbourhood of Antioch in Syria, consisting of the survivors of the inhabitants of five villages after 45 days' fighting with the Turks; they were in a very debilitated condition. The children under 14 numbered 1563. These unfortunates were accommodated in camp on the eastern side of the Suez Canal, occupying the buildings of the quarantine lazaretto and tents pitched on the neighbouring desert ground; the camp was carefully laid out and its sanitation well looked after. The water-supply was derived from the Port Said Water Company and was ample and satisfactory. About the beginning of February, 1916—that is, four and a half months after the arrival of the refugees—stomatitis and diarrhoea began to be prevalent. Two months later a symmetrical rash on the hands was noted in two or three cases. These increased in number, and early in May were recognised to be pellagra. By the middle of June some 400 to 500 of the refugees were showing signs of this affection, the cases being distributed throughout the encampment. The condition was more marked among the older people, and of the 1200 children attending school only 50 showed any symptoms, and these were of a very mild type. It is to be noted that the school children received two small buns daily in addition to the usual ration. There was some improvement in July, but in September the number of cases increased, and there appeared to be an exacerbation of the symptoms. The total cases amounted to 639 in 1916 and 14 in 1917. Of this total (653), 79 per cent. were among females. The age varied between 4 and 95, averaging from 20 to 50 years. The duration averaged five months, and the mortality (38) was at the rate of 5·8 per cent. of the cases. A revised dietary was drawn up in October, 1916, and a special "anti-pellagrous" diet, including fresh foods and milk, was issued in February, 1917, the fatty elements being raised from 46 to 90 g. daily. From this time pellagra began to diminish, and no fresh cases occurred after June, though old cases still appeared from time to time at the out-patient dispensary. Opportunity was afforded in July, 1916, for comparing the condition of these Armenian refugees at Port Said with that of a large number of Jewish refugees at Alexandria. It is estimated that 10,000 of these latter arrived between the end of 1914 and the time of this inspection, but only 2080 were then remaining in the encampments, the rest having left for Armenia and elsewhere. There was a very marked difference in the physical conditions of these two collections of refugees. The difference in the official food rations supplied to each was very slight as regards nutritive value; but the Jews were mostly town-dwellers, continuing to lead a life not unlike their former condition, and were able in many cases to obtain some employment, and so supplement the food supplied to them. It was noted that the Armenian refugees, who were accustomed to olive oil, disliked the cotton-seed oil supplied, and that this was not the case with the Jews, who consumed distinctly more oil. The Jews also were supplied with wheaten bread, while that given to the Armenians at Port Said had 25 per cent. maize mixed with the wheat flour. Dr. White, in concluding this very interesting report (which is fully

illustrated with photographs and diagrams), observes that the weight of evidence points entirely to a faulty diet as the causal factor of the outbreak, and that pellagra was eradicated by correcting the faulty dietary, all other conditions remaining the same. Maize may have been a factor, but "certainly had no direct causal relation to the disease, and when an adequate and properly balanced ration was given pellagra disappeared." In regard to the theory of transmission by means of a biting fly (*Simulium*), "nothing of the nature of a protozoal cause could be discovered, nor could any connexion with biting insects be found."

SIR NORMAN LOCKYER.

THE death of Joseph Norman Lockyer, announced this week, will be regretted by a wide scientific circle. He was born at Rugby in 1836. A shrewd and acute observer, he contributed valuably to his own science, that of astronomy, and well earned the Fellowship of the Royal Society awarded in 1869. The year before he had found the helium spectrum line in the sun, a discovery which led the way to the search for terrestrial helium. This gaseous element, as we all know, was subsequently found, and is now playing an important rôle in aeronautics, since, while it is buoyant, it is, unlike hydrogen, non-combustible; and a practical development of its application has been begun in Canada, where it is derived from natural gases. Sir Norman Lockyer did a further service to science when he started the first number of *Nature* in 1869, a journal which soon attained the authoritative position which it has held ever since. Lockyer was created K.C.B. in 1897.

SUBCHRONIC LETHARGIC ENCEPHALITIS.

IN the second number of the *Wiener Archiv für innere Medizin* (Bd. I., Hft. 2, June, 1920), which is being published under the supervision of Professor W. Falta and Professor K. F. Wenckebach, there are seven original articles, the quality of which is all the more striking when the deplorable conditions obtaining in Vienna are considered. In one of these articles Dr. Constantin Economo records in detail a case which shows that lethargic encephalitis may run a subchronic course, terminating fatally after nearly two years of ill-health.

The patient was a man, aged 45, whose illness began on April 5th, 1917, with profuse perspiration and pains in the limbs and back. A few days later his temperature was found to be 38°C. and he was very drowsy. Meningitis being suspected, he was admitted on April 26th to hospital, where he lay unconscious. There was marked rigidity of the body and his head and limbs were extended. No paralyses or loss of reflexes could be discovered, but the reflexes of the abdominal wall were considerably reduced. He groaned, but did not speak, and had to be fed artificially. When light was flashed on his eyes he would turn his whole head away without apparently moving his eyeballs. By June 2nd the drowsiness had passed off and he was less apathetic; he could sit up in bed without help, understand what was said to him, and in large, clumsy handwriting he could show that he understood simple questions, but speech was limited to inarticulate sounds. Later in the summer of 1917 his general condition was better; he could walk, and, as his writing showed, there was no aphasia. There were no sensory disturbances, but certain curious choreiform twitchings of his fingers had developed. At first he could suppress these movements at will. By the end of August they had extended to the lower limbs, causing him considerable discomfort. Wassermann's reaction was negative, and lumbar puncture yielded clear, sterile fluid under little pressure. In 1918 the athetosis diminished, but there was no improvement in the disturbances of speech. He choked over his food and gradually lost ground, becoming apathetic. In spite of careful nursing he became profoundly cachectic and died early in January, 1919.

The most significant feature of the post-mortem examination was the demonstration in various parts of

the central nervous system of both old and recent foci of inflammation. It would thus appear that after the fulminating onset of the disease the organism had been unable to eliminate the virus which had persisted, giving rise to chronic, slowly progressive inflammatory changes. Ultimately they wore the patient down. As Dr. Economo points out, epidemic encephalitis usually terminates in death or complete recovery; the recorded cases of survival of the disease with persistence of a paralysis or some other symptom are very rare. But as this case shows, the disease may remain smouldering for nearly two years, with signs of extension of the inflammation from one part of the brain to another.

THE PROBLEM OF DENTAL DISEASE.

THE deplorable state of the nation's teeth is only too well known, and health authorities are busily engaged in promoting schemes for treatment. At the recent meeting of the British Dental Association at Bournemouth, the chief interest centred around this perplexed problem of the dental needs of the public. Dr. R. A. Lyster, the medical officer for Hampshire, pleaded in eloquent terms for further research into dental disease, and from his remarks as reported it would seem that the fundamental causes of dental disease are unknown and that it is therefore useless to lay down definite rules for prevention. This statement, if it gains currency, will tend to undermine belief in the excellent work that has been done on the ætiology of dental disease and on which the present rules for prevention of dental disease are based. These rules have already stood the test of time and produced excellent results, and have abundantly confirmed the correctness of the views held on causation. Speaking in a general sense, dental caries is due to the altered character of the carbohydrate diet and the enormous consumption of sugars, especially those of the mono-saccharide group. In the case of periodontal disease also it is clear that the lodgment of food in the interdental spaces is a prominent factor. Mr. R. Lindsay in his public lecture admitted that the remedy was largely concerned with food, but considered that to ban any common foodstuff was outside the sphere of practical politics in the question of the prevention of dental disease. But surely, if one is convinced of the cause, it is culpable negligence to evade the teaching of prevention simply because the obstacles to a radical change in diet appear too great. The stoutest wall will give way before constant battering, and so with this question of food and dental caries. Dentists may be appointed to schools, to the army, to the navy, to maternity centres, but little headway will be made towards the banishment of dental disease unless the simple rules of prevention are inculcated. It is, indeed, a stigma to medicine that the most prevalent disease of the human race is the most easily preventable. If the Ministry of Health will concentrate on teaching prevention by means of popular lectures, illustrated with lantern-slides, and by booklets written in simple language, in the course of two generations we shall see an end to preventable dental disease, and there will be but little need for an elaborate public dental service.

THE "DORSAL POINT" IN HEPATIC COLIC.

IN *Lyon Médical* Dr. Raymond Pauly has described a sign which appears to be of considerable value in the diagnosis of hepatic colic. He points out that in this condition, as in all analogous syndromes, there are subjective and objective pains. The subjective pains are generally vague, whether in their form and intensity or in their localisation and radiations, and therefore are not of great diagnostic value. Such is the pain in the right shoulder in hepatic colic. It is seldom described spontaneously, and when asked to show its position the patients indicate vaguely the right shoulder and some even indicate the left. The radiations of the pain are numerous. Professor Chauffard

described those which occur in the area of the right phrenic nerve, in the supra-clavicular, supra-deltoid, supra-mammary regions, at the angle of the scapula, and at the eighth, ninth, tenth, and eleventh dorsal spines. The greater part of these radiations are purely subjective and do not correspond to a point at which pain can be provoked by pressure of the finger. But there are two such objective points—the epigastric and the cystic; the abdominal pains, however, being often so intense that it is difficult to demonstrate these points clearly. Dr. Pauly therefore tried whether the vague pain felt in the right shoulder corresponded to a painful point, and in 21 cases constantly found a point tender on pressure between the spinous processes of the vertebrae and the border of the right scapula at the level of the fourth or fifth intercostal space at a distance of 2 or 3 cm. from the middle line. This point is therefore very different from that described by Professor Chauffard in the position of the eighth to the eleventh dorsal spines. Dr. Pauly terms this the "dorsal point" (*point dorsal*). The best means of testing for it is to seat the patient on the bed, with the arms in front to give support. The observer, standing on the right of the patient, presses with his left thumb on the different intercostal spaces between the spine and the right scapula, from above down. On arriving at the fourth or fifth space a painful grimace is provoked, and the patient often sits up brusquely, complaining of severe pain. As a means of control it is always useful to apply the test on the left side. Some patients complain also of pain on this side, but it is less severe. The intensity of the pain varies. Sometimes a cry of protest is provoked; at other times the patient simply says that a little pain has been produced. As a general rule, the intensity of the pain varies directly with that of the colic, and it gradually diminishes as the other symptoms pass off. Is this point more important than the points already described? According to Lejars, the cystic, epigastric, xiphoid, and costal (extremity of the twelfth rib) points may be found in other affections than hepatic colic—in gastric, colic, and appendicular affections. The dorsal point must be distinguished from the "painful points" of intercostal neuralgia, which are near the spine itself and not 2 or 3 cm. distant. Further, the other neuralgic points—lateral, anterior—will also be found. It is important to prove the absence of the point in other painful affections which have to be differentiated from hepatic colic. Dr. Pauly has found the dorsal point absent in gastric and duodenal ulcer and acute appendicitis. Its diagnostic value therefore seems to be established. What is its pathogenesis? The motor and sensory supply of the biliary passages comes from the great splanchnic nerves which originate in the thoracic ganglia of the sympathetic from the fourth to the tenth, but the upper roots are the most important. The communicating rami of these ganglia run in the corresponding nerve roots, and can thus affect the nuclei of the corresponding sensory nerves. Thus the sign is due to hyperæsthesia of the area of distribution of the posterior branch of the fourth and fifth dorsal nerves. A matter which is not explained is, Why is not the painful point of hepatic colic at the same site as that of intercostal neuralgia?

THE U.S.A. AIR MEDICAL SERVICE.

THE Medical Service of the United States Air Force has been reconstituted since the war, and is described by Colonel A. E. Truby and Major John Dibble of the Medical Corps, U.S. Army, in the *Military Surgeon* for July. The Air Force is organised under the War Department, as is the Air Service, and its chief surgeon, Colonel Truby, is an officer of the Medical Corps. Shortly after the armistice a Director of the Air Service was appointed, who requested the Surgeon-General (Medical Director-General) to transfer the Air Division of the Surgeon-General's office to the Air Service. This was approved and the Medical Division of the Air Service was established, with the Chief Surgeon of the Air Service in charge. The specialised condition of the

Air Service, the work of the flight surgeons, the Medical Research Laboratory at Mineola, N.Y., and the highly technical examination of aviators, explain why the Air Force requires a special medical service not given to cavalry, for example, or artillery. The active flying fields are under the local commands, who are informed that flight surgeons are not available, nor are physical directors, for routine garrison work, except under very special circumstances. The flight surgeon is a selected officer of the Medical Corps, probably a pilot (with 25 per cent. extra pay like all pilots), and so with a complete knowledge of the needs and difficulties of aviators, and thoroughly in sympathy with them. On his recommendation other medical officers will take flying training so as to understudy him if required. He lives with and associates with the aviators constantly; he knows them well and can determine when they should not fly, and what sleep, food, and amenities they should have. He sees, on transfer, all officers who fly or are under flying training. An officer who volunteers for training as an aviator undergoes a very specialised medical examination, with particular attention to stereoscopic vision, field of vision of each eye for form and colour, and latent hypermetropia, which has caused crashes of officers when fatigued. The nervous system undergoes psychological investigation, and defects cannot be waived by examiners, but only by the Surgeon-General of the Army. This examination can only be made by selected officers designated by the Surgeon-General who have been through the examination course at the Medical Research Laboratory. The examination report is in triplicate. One copy remains at the station, and two are sent to the Director of the Air Service for the chief surgeon; of these one with his remarks remains in the Director's office, while the other is returned to the flight surgeon. The Chief Surgeon has a card index of officers, their examinations, crashes, and so on, and is accumulating statistics, which in time will decide the ages for receiving cadets, length of service for pilots, why pilots wear out, who should fly with what planes, and so on. The Chief Surgeon is forming a library, and air ambulances to rescue men who fall in deserts or otherwise out of reach are being devised. He supervises the medical research laboratory, and an "Air Medical Bulletin" is announced. The work of the Medical Service appears to be welcomed by the Air Service; it is certainly of great value to the force, and must prove useful also to general medicine in the United States. We indicate elsewhere the value to civil medicine which has been shown to emanate from the researches of the medical department of our Air Force.

Dr. Philip John Hensley, consulting physician to St. Bartholomew's Hospital and sometime Censor to the Royal College of Physicians, died at Farnham on August 8th in his eighty-second year.

As will be seen in our Parliamentary Intelligence, on the eve of rising for the recess Dr. Addison introduced in the House of Commons a Bill, which was read a first time, embodying a number of far-reaching provisions in regard to housing, hospital accommodation, and the reception of early mental cases. It is proposed to give to all the larger local authorities—those of counties and county boroughs—power to supply and maintain their own general and special hospitals, to make contribution to voluntary hospitals within their areas on terms acceptable to the Ministry of Health, to maintain Poor-law hospitals and infirmaries, and to keep up a local ambulance service for accident and illness.

WEYMOUTH AND DORSET COUNTY ROYAL EYE INFIRMARY.—The annual meeting was recently held at Weymouth. The institution was established in 1836 by Mr. Charles Bridge, and he was the first surgeon to the infirmary. The medical report stated that for the 12 months ended June 30th, 1920, the in-patients admitted were 80, and the out-patients numbered 803. The financial statement showed a favourable balance of £112.

ECONOMIC CONDITIONS IN VIENNA: THE FATE OF THE UPPER MIDDLE CLASS.

A REPORT written by Marjorie Vernon, a member of the Friends' Relief Mission in Vienna, and issued by the Friends' Emergency and War Victims Relief Committee (27, Chancery-lane, London, W.C.2), pictures the desperate, and apparently hopeless, position of the educated middle class in that city. Although the report deals with this class as a whole, it may be taken as applying specifically to the members of the Viennese medical profession. The general condition of malnutrition set out constitutes in itself a medical problem.

Numbers Involved.

Of the total population of Vienna, stated as 1,838,708, an undue proportion—namely, about 352,000—are upper middle-class people, and these were made up, according to the census of 1910, in the following way:—

1. Court, State, and other public officials	75,000	139,000
Plus dependents		
2. Teachers, professors, and all those concerned in education	15,000	25,000
Plus dependents		
3. Other professions (lawyers, doctors, artists, &c.)	15,000	29,000
Plus dependents		
4. Small property owners—people living on investments	52,000	106,000
Plus dependents		
5. People in institutions (orphans, &c.)		43,000
People preparing themselves for professions (students, &c.)		342,000
6. Present estimate of number of officers in Vienna		10,000
		352,000

And the list is not complete for it does not include bank and other private officials, or any shopkeepers. A considerable number are new-comers without employment, or people who have lost their work and subsist on their pensions.

The Middle-class Balance-sheet: Yearly Budget of a Family in England and Austria Compared.

* Denotes the rationed quantities.

† Quantities assumed to be smuggled in.

Now, although the wages of the Viennese workers are on an average between 23 and 33 times what they were in 1913, the incomes of the "Mittelstand" have only increased four to eight-fold, while the salaries of pensioners have hardly risen, and the income of people who live on their investments not at all. But on the

expenditure side, the yearly budget of a middle-class family in Vienna, consisting of father, mother, and two children, now compares, as shown in the table given above, with that of a similar family which buys the same things in England at English prices.

The result shows that £292 odd buys the same amount of goods in London as 176,000 kronen will buy in Vienna, and it will be observed that this budget makes no allowance for clothes, rates and taxes, insurance, doctors and dentists, holidays and amusements, education, books and newspapers, wine and tobacco, replacement of furniture, house linen and kitchen utensils, or domestic service. This whole budget, which only includes the bare essentials of life, comes in Vienna to 176,000 kronen. The highest salary, with very few exceptions, which anyone gets, is 96,000 kronen, and this is far in excess of the average.

Typical Examples of Privation.

The report goes on to give concrete instances of the actual lives of representative middle-class folk under this régime. We transcribe two of them.

The man is a Finanzsekretär in the Government service, and before the war he earned 3600 kronen a year. In those days he lived at Krems—a town about three hours journey from Vienna—with his wife and four children, a boy and three girls. He was quite well off, kept a servant, and lived very comfortably. His income has now been raised to 42,000 kronen. On this income he finds it impossible to keep his family together at all. He has left his wife and the little boy in Krems—the eldest girl has got work for which she is paid 12,000 kronen a year. The two little girls of 12 and 14 have been sent to a boarding school which costs him 600 kronen a month. He himself has come to live alone in Vienna in one little room for which he pays 80 kronen a month. These are favourable terms as the landlord happens to be a friend of his. For his midday meal he goes to the Gemeinschaftsküche (it corresponds to our war-time national kitchen), where he pays only 7 kronen for his meal and gets soup, vegetables, and a mehlspise, which corresponds to our pudding. Nowadays in Vienna a mehlspise is often just a piece of slightly sweet bread or perhaps cooked tapioca with cinnamon and sugar sprinkled over it. These Gemeinschafts- and Kriegsküchen are depressing places; sometimes they are underground, always they are dismal. You see long tables covered with dirty table-cloths at which rows of shabby disheartened people sit, silently lapping up watery soup or stodging through mounds of potatoes and vegetable marrows. One aluminium spoon and fork suffices for the whole meal. In the evening, however, our friend the Finanzsekretär has to go to a restaurant, as the kitchen is closed. There he will find it hard to dine under about 20 or 25 kronen, and if he wants any meat he will have to pay about 40 kronen more. To add to his troubles his little girls are both unwell—one has had pleurisy, and the other child has to see an oculist—all causes of additional expense.

A man of 31, who is an assistant lecturer on Eastern European languages and history at the University. He has a wife and one child of 8, and his salary is 21,600 kronen a year. He pays 720 kronen in rent and 480 for light a year. The whole family go to the Gemeinschaftsküche for their midday meal, which costs them 9 kronen each. The child is very delicate and underfed, although the parents make tremendous sacrifices to buy her three or four tins of condensed milk each week. Each tin has to be smuggled in and costs 50 kronen. Professors' salaries, of course, vary considerably, but in no case do they ever approximate to a real living wage. I have before me a list of some half dozen professors—personally known, but quite average cases. Here are two samples: A professor of a university, 53 years old, with a wife and two children—his total salary is 20,000 kronen a year. An assistant professor, 58 years old, with a wife and three children—his total salary is 19,690 kronen a year; and one could quote such cases indefinitely. There is, however, a further tragedy involved for these professors. They have not enough to eat; they cannot clothe themselves or their families properly; but besides this they cannot even pursue their work without being held up at every point. All printing, for instance, has gone up by at least 2000 per cent. in the last year or so. Then the interchange of scientific papers and magazines between the professors and universities of different countries has practically ceased. For even were the countries willing, Austria, even in this sphere, has very little to give. Scientific research, again, is only persevered in against fearful odds. The prices of things needed for an ordinary chemical laboratory have risen by about 4000 per cent. Ordinary drugs and chemicals are anything from 40 to 100 times as dear as before the war. There was a little while ago an almost comically pathetic article in a newspaper by a doctor engaged in research work. He wrote most

despondently about the terrible cost of rabbits and guinea-pigs—essential for research work—and lamented bitterly that people nowadays eat them in such vast quantities as to make them almost worth their weight in gold. The letter made one smile, yet it revealed the hopeless blank which faces people here whichever way they turn. They are hungry and cold and turn to their work for help, and there the same spectre of despair faces them again.

The Health of School Children.

The net result of all this suffering is practically impossible to get in figures, which apply only to the middle class. Mrs. Vernon has only been able to get one set of figures where the middle class can be picked out and compared with the working class. There is now going on in Vienna a medical examination of all school children under 14 years of age. This examination is specially an inquiry into underfeeding and anæmia. The children are divided into three classes, the first class being the best and the third the worst fed. Vienna is divided into districts and the results in each district are grouped together. In the following table four middle-class districts are compared with three working-class districts:—

A. Middle-class districts—number examined 9308.			
% children in			
	Class I.	Class II.	Class III.
1	38.4	15.2	46.4
2	25.4	53.3	21.3
3	18.0	45.6	36.4
4	11.8	20.6	67.6
Average	23.4	33.7	42.9
B. Working-class districts—number examined 41,194.			
% children in			
	Class I.	Class II.	Class III.
1	14.4	38.3	47.3
2	47.2	26.4	26.4
3	19.5	34.0	46.5
Average	27.0	32.9	40.0

It will be seen that the middle-class districts show slightly worse results than the working-class districts. Mrs. Vernon went with the school doctor to see the medical examination in progress, and reports:—

We first went to a school which is situated in one of the healthiest districts of Vienna. This district is chiefly inhabited by middle-class people, it is almost outside the town and lies very high. The air is fresh and pure, and in normal times the children are particularly healthy. Later we visited a school where the children come almost entirely from working-class homes. The district has the reputation of being one of the worst in Vienna—it lies low, the houses are more crowded together, the people more ignorant. And yet one undoubtedly got the general impression that the children in the middle-class school were worse developed, were whiter and thinner than those in the working-class school. The school doctor also bore this out, and it really does appear to be true. When one thinks of all the advantages which middle-class children have—the air space first and then the intelligence in buying food, the care and thought, the cleanliness, everything in the child's favour—these facts and figures are rather striking.

Can and Should Relief be Attempted?

In concluding the report Mrs. Vernon raises the question whether middle-class relief is a right thing to undertake at all. Some may feel that in a country where the bare necessities of life are unprovided for, where for many years to come no one will have money to spend on anything but bread and butter, a cultured middle-class does not stand a chance of surviving, and that to keep it alive is merely to foster an artificial state of society which, if left alone, would readjust itself and reach a position of stable equilibrium more quickly, and therefore ultimately with less suffering, than if relief agencies intervened. She answers her question with another:—

"When, however, the next generation grows up, what will it say if we have saved the men who worked to feed and clothe humanity, but allowed those to die whose work was to keep civilisation alive? In Vienna, especially, the professors, doctors, artists, musicians, and sculptors have a claim which cannot be denied."

How the apparently impossible is to be achieved and the upper middle class in Vienna, including the doctors, is to be saved, upon this the report does not enter. The facts are recorded without minimising or exaggerating their significance.

MEDICINE AND THE LAW.

Godman v. Maclean.

IN this action the patient sued a medical man for damages for alleged negligence in the use of cocaine. The drug was employed as a local anæsthetic in operating on a small cyst of the hand, a 5 per cent. solution combined with adrenalin being injected. After the injection of 5 minims it was found that the requisite anæsthesia had not been produced, and a further injection of 5 minims was made when alarming symptoms followed. An illness lasting 3½ years, from which the patient had only partially recovered, was ascribed by the plaintiff to the effects of the cocaine, and this was apparently not in dispute. The only question, indeed, for Mr. Justice Salter who tried the case was that of the alleged negligence. The negligence, his lordship said, was alleged in three ways: (1) That it was negligent to use cocaine for hypodermic injection at all; (2) that too large or too strong a dose was administered; (3) that there was unskilfulness and carelessness in the actual administration of the second injection. It was contended that cocaine as used was obsolete, and known to be obsolete and dangerous. As to this, his lordship understood from the evidence before him that the risk was practically confined to persons abnormally sensitive to the drug, a peculiarity of the patient not discoverable beforehand. With regard to the danger of using cocaine the relative merits of other drugs for the same purpose and the correct dosage he was satisfied from the evidence called on both sides that the highest medical opinion was not in agreement. He had the evidence of chemists and of pharmacists that cocaine was still widely used, and that although the proportion prescribed was frequently less than 5 per cent., that proportion was used if the strength was not mentioned because it was the strength prescribed in the British Pharmacopœia. In fact, cocaine was included in the British Pharmacopœia for the purpose and in the proportions in which the defendant had used it, and he had the evidence of the defendant as to his own experience in the employment of the drug. A medical man could not be convicted of negligence for having administered a preparation agreeing both in strength and amount with the British Pharmacopœia, and of which, moreover, he had had satisfactory experience for many years. As to the suggestion that a small vein had been pierced in making the second injection, even if this had been so there evidence before him that it was possible to inject cocaine into a small or even into a larger vein without danger to a normal person, such as evidence showed the plaintiff apparently to be.

In giving judgment for the defendant his lordship expressed deep sympathy with the plaintiff. Costs were not asked for on behalf of the defendant, and a counter claim was not pressed, the plaintiff's counsel expressing her thanks to the defendant for his attitude in this. The defendant and the London and Counties Medical Protection Society, who supported him, are to be congratulated upon the conclusion of a professional experience which must have caused the former considerable distress and anxiety.

Hypnotism and the Law.

It is sometimes made a subject of unfavourable comment that there is no specific legal provision in the United Kingdom against the abuse of hypnotism by unscrupulous persons, and the reviews of a recent book have called attention to the position. The existence of a danger of this kind appears to be recognised in some other countries. In Belgium, at any rate, it has for many years been illegal to hypnotise, or cause to be hypnotised, any person by way of public exhibition. In a similar manner penalties of fine and imprisonment may there be imposed on anyone who, not being a medical practitioner or the holder of a Government licence for the purpose, hypnotises a person who is under 21 years of age or is of weak mind. A penalty also is provided for anyone who, with the intent to defraud

or to injure anyone, causes a hypnotised subject to write or sign any document embodying an obligation. Any person uttering or making use of any document so obtained is equally punishable. Whereas, however, hypnotism might be made the subject of legislation in this country by way of precaution and in order to deter possible evil-doers, it has not been found apparently that public exhibitions of hypnotism have been a serious source of danger to the public, or that the control exercised by the hypnotiser has been made use of for criminal purposes in any manner with which the existing law cannot deal. Probably with us the most serious danger to the public lies in the freedom of the quack to exploit hypnotism for alleged therapeutic purposes; and the most useful and effective way to protect the ignorant from being imposed upon, and the public generally, would be to forbid the exercise of hypnotism for any purpose except by, or under the control of, a medical practitioner. Meanwhile, none but foolish persons will trifle with hypnotism or invoke its aid except under medical advice.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

The Authority of the Local Government Board in Ireland.

IN many parts of Ireland the authority of the Local Government Board is being flouted. At a meeting of the Cavan board of guardians an order has been made that no books or documents be produced for inspection of auditor or other official of the Local Government Board, and that minutes of its proceedings be sent to Dail Eireann (the governing body of Sinn Féin). The clerk pointed out that the grants received by the board of guardians totalled £3262, and by the district council £3032. It was explained that (in accordance with the recent circular of the Local Government Board) these grants would soon be stopped. Co. Cavan Council also has ordered that in future minutes and correspondence be sent to Dail Eireann only, and a special committee was appointed to consider the financial position that might be created by the withdrawal of grants made by the Treasury. The Cavan board of guardians has decided that policemen's wives holding positions as district nurses under the board should be called upon to resign. The Finance Committee of the Donegal County Council has decided to refuse payment of a sum of £14 14s. 11d. for medical and nursing expenses incurred in connexion with police injured near Dungloe on Dec. 12th, 1919. The money was paid to the infirmary authorities, and the Lords Justices have certified for its payment as mentioned in a letter sent by the under-secretary of the Lord-Lieutenant to the Donegal County Council, and requesting that an order payable to the under-secretary be returned by the council at an early date.

The Irish Public Health Council's Report.

Although the report of the Irish Public Health Council was issued almost two months ago, no public action on it has so far been taken by the medical profession. Whether, indeed, any legislation will follow is extremely doubtful, for if the present Home Rule Bill becomes law, it is probable that it will be left to Ireland itself, or to the two parts of Ireland involved, to carry out whatever measures they like. It is believed that local medical committees will be soon asked, in various places, to discuss the report and to instruct delegates to represent their views at a meeting of the medical profession, to be subsequently held in Dublin, as to whether the report is to be accepted or not, or modified before its acceptance.

Vital Statistics.

Some interesting statistics are found in the return of the Registrar-General for the first quarter of 1920. The birth-rate for the quarter—23·9 in every 1000 of the estimated population of Ireland (4,470,000 for 1920)—is 1·7 above the average rate for the corresponding quarter of the ten years 1910–1919, and 3·9 above the rate for

the first quarter of 1919. The death-rate (16·9 per 1000) is 8·8 below the rate for the same quarter in 1919, and 4·3 below the average for the first quarter of the ten years 1910-1919. Curiously the returns of pauperism show an increase of 320 in the average number of work-house inmates, and an increase of 784 in the average number of persons in outdoor relief, and this at a time when wages in every department of industrial life never were so high. The marriages registered in Ireland in 1919 were 26,977, and oddly, the largest number, 7241, were registered in the third quarter (July-September). Of the deaths registered in the first quarter of 1920 (there were in all 18,882) epidemic diseases caused 974 (0·87 per 1000 living), being 0·14 above the average for the first quarter of the five preceding years. Whooping-cough comes first, with 279 deaths, then measles with 208, diarrhoea with 159, diphtheria with 133, scarlet fever with 129, enteric with 54, dysentery with 9, and typhus with 3. There were in the quarter under review 2023 deaths from all forms of tuberculosis, equal to an annual rate of 1·81 per 1000 of the Irish population, while the deaths of infants under one year old are equal to 90 per 1000 births.

August 16th.

Public Health.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

THE HEALTH OF LURGAN (ULSTER).

IN a country where "sanitary matters are at least 30 years behind the state of administration in the rest of the United Kingdom" it is pleasant to come across a record of such admirable work as is contained in the interesting report of Dr. Samuel Agnew, the medical superintendent officer of health of Lurgan urban sanitary district, for the year 1919. During the time that he has been officially connected with Lurgan (40 years) lanes and courts have been abolished, all dwelling-houses have been provided with separate conveniences and tiled yards, and a public water-supply installed since 1895. This water is pumped up from Lough Neagh to filtering beds and then conveyed to Lurgan. At one time, acting on expert authority, Belfast declined to take water from Lough Neagh, but the advice has since been proved to be wrong by the practical experience of Lurgan—one of Ulster's most progressive industrial towns—where, since 1895, when the Lough Neagh supply was begun, no epidemic usually ascribed to impure water-supply has occurred. In 1919 the average death-rate in Lurgan was 16·5, the birth-rate 22·0, and the infantile mortality was only 52 per 1000 births, and there was not a single death from small-pox, typhus, enteric, scarlet fever, diphtheria, measles, or whooping-cough. Dr. Agnew expresses grave disappointment with the working of the Tuberculosis (Prevention) Act. Formerly the prescribed conditions relating to the notification of tuberculosis, applied only to the pulmonary type, were that the persons to be so notified must be habitually sleeping or working in the same room as other persons or employed in the preparation and distribution of articles of human food intended for sale to the public. An amended Order was issued last year by the Local Government Board by which notification—in Ireland—applies in every case in which a person, not being at the time in receipt of institutional or other treatment under an approved scheme for the treatment of tuberculosis, is suffering from tuberculosis of any form at any stage in which the sputum or other infective discharge of, or from, such person is, in the opinion of the medical practitioner attending such person, liable to communicate the disease to other persons. The objection even to this improved form of notification is that in most cases the disease has so far advanced (to fulfil the conditions) that notification is too late and that nothing at all is being done to prevent the bovine form of the disease. In Ireland hardly anything is being accomplished in the prevention of tuberculosis, sometimes called the "Irish disease," now, just as typhus was in former times. An

admirable maternal and child-welfare scheme, with pre-natal department, is in active work in Lurgan, which is really one of the most advanced public health towns in Ireland.

SCHOOL MEDICAL INSPECTION.

BIRMINGHAM.

The number of children on the school registers in Birmingham (December, 1919) was 153,648, and the total number examined at the routine inspections during the year was 40,515; the total number of cases treated at the various clinics was 50,853. The percentage of defects treated was 69·5. Analysis of the cases of defective vision treated by Dr. R. Beatson Hird shows that out of 723 fresh cases examined 595 were found to require glasses. Of these, 73·3 per cent. were cases of hypermetropia (160) or hypermetropic astigmatism (277), and 26·4 per cent. were cases of myopia (51), myopic astigmatism (71), or mixed astigmatism (36); that is, astigmatism in one form or another accounted for 64·4 per cent. of all the cases of visual defect.

Convergent squint.—Dr. A. W. Aldridge, who also treated eye cases, emphasises the importance of very early treatment—"within a month of first attendance at school." Neglect or delay in treatment leads to permanent disturbance of vision, as the squinting eye is not used. By placing a pad of wash-leather over the good eye (two layers of wash-leather a little larger than the frame of the spectacles, so that the glass is covered by it on each side like a muff, the wash-leather being stitched round the glass), the squinting eye is made to do its work.

"When the sight in each eye is practically equal (usually after three or six months) the shade is worn on alternate eyes, and after the lapse of another year the vision in each eye will often be about 6/9, with an alternating squint."

In favourable cases this will entirely disappear, but the shading must be continued for an hour or two each day for a long time after apparent cure, as relapses are still apt to occur.

Tonsils and adenoids.—There was considerable increase in the number of children operated on for these—1429 compared with 1021 in the previous year; moreover, the waiting list of children needing treatment at the end of the year represented nearly a whole year's operations.

"These figures give cause for thought and inquiry. Either the tonsils (including the tonsillar tissue, enlargement of which is known as 'adenoids') have a definite physiological function, with which we interfere at a certain cost to the organism, or the enlargement is a reaction against some morbid cause. . . . There is little doubt that the enlargement of these tissues is, in fact, due to an infective process, spread like other infections, possibly as a result of the aggregation into schools."

Open-air conditions are indicated.

Ringworm has been treated by means of X rays with great success; in 1911 the cases of ringworm were estimated to be as many as 1400; in 1912 and 1913 the numbers of cases known to exist were 2281 and 2131 respectively; at the end of 1919 the total number awaiting examination and treatment was only 37. This very satisfactory result is due entirely to the introduction of X ray treatment, and in not a single case have any permanent patches of baldness been left.

Tuberculosis shows an improvement in 1919 over the preceding years, not only those of the war period (when the incidence "was probably a reflex of the lowered health margin due to war conditions"). The notified cases among children up to 15 years of age, which were 732 in 1913 and 918 in 1916, have fallen to 844 in 1917, 716 in 1918, and 588 in 1919. Open-air treatment is carried out at the Yardley-road Sanatorium.

Influenza is said to have "caused a heavy mortality amongst the child population of the city." No details are furnished, and the number of deaths (among children of school age, 5 to 15) is stated as 42, compared with 223 in the previous year (p. 35); on p. 21 the deaths in 1918 between 5 and 15 years of age are stated as 357.

Open-air teaching is carried out to a considerable extent by means of an open-air school at Uffculme, a

"roof-class" at St. Thomas's and St. Alban's, and playground classes at several schools.

Disinfecting apparatus.—The need here is great. It is to be regretted that 35 per cent. of all the children examined showed the presence of vermin; some improvement, however, has been effected, as 64·81 per cent. were found to be "clean," compared with 56·6 per cent. in 1915. Scabies has increased in prevalence (1202 cases treated, compared with 603 in 1917). This has been largely due (as elsewhere) to return of infected soldiers from active service. Unfortunately, only one of the clinics is provided with a disinfecting apparatus; accordingly the children in many cases have to put on infected clothing after being bathed. The need for increased facilities for disinfecting clothing is obvious. Birmingham, according to the last census (1911), ranks as the largest city in England after the metropolis, and when once the urgency of this requirement is recognised there can be no doubt that the deficiency will be made good.

BRISTOL.

In his report to the Bristol Education Committee for 1919 Dr. R. A. Askins, the school medical officer, draws attention to the fact that "one of the lessons of the war has been the realisation of the large amount of physical unfitness in adults due to want of care and treatment during childhood, and consequently a powerful incentive has been given to improve and enlarge a work which has for its object the raising of the standard of health of those children who are to form the future of the race." The full scheme of medical inspection has been again brought into action, and both the central clinic and that at Bedminster have been reorganised and the work extended. The importance of the help given by head teachers, as Dr. Askins remarks, cannot be over-estimated, and they, in return, recognise the help given them by the school medical officer in regard to absentees, &c. Reference is also made to the valuable work of the school attendance department: a large number of refractory cases are interviewed personally by the superintendents, who seldom fail to secure the compliance of the parents. In this way the school authority is often spared the trouble and unpleasantness of undertaking a prosecution for non-attendance. The full scheme of inspection in detail has been resumed since April, 1919, the total number examined in the code groups of entrants, 8-year-old children, and leavers being 19,374; besides which there were 5696 specially examined.

Defects requiring treatment that bulked most largely in the routine examinations (code groups) were as usual teeth and throat cases, 1360 of the former and 1223 of the latter, in addition to 253 and 69 respectively needing to be kept under observation. Malnutrition was considered to need treatment only in 29 children out of the whole 19,374 in the code groups, and only eight others were specially brought forward as needing care on this account. No evidence of physical deterioration in the young, due to the special economic circumstances of the times, can be gathered from these statistics. Organic heart disease was diagnosed in 113 children, and definite tuberculosis only in 25, though its presence was suspected in 125 others. Three inspection clinics are held in the city, where special cases are sent by head teachers, nurses, and attendance officers. Of the 4622 children who were treated more than half (2444) were cases of skin disease (ringworm, impetigo, scabies, and vermin), compared with 1892 in the previous year.

"One is horrified at the high percentage of girls with lice in their hair. . . . The condition is so common that parents still regard it but lightly, and one of the first things necessary is to teach the girls themselves how serious the matter is."

It is also stated that the condition is much more common among secondary school girls than had been expected. Ringworm of the scalp was found to exist in 427 children, causing absence from school on an average for 24·2 weeks, or roughly six months. Treatment by X rays is being arranged for. Scabies (517) and impetigo (948) were also prevalent. Arrangements for treating the former disease are being made by the

provision of a bathroom at one of the clinics; it is, however, undesirable that children with this complaint should be mixed up with other children at an ordinary clinic; a separate clinic with suitable bath accommodation is much to be preferred.

Referring to tuberculosis Dr. C. J. Campbell Fail reports that—

"a much larger proportion of the juvenile population is infected than had previously been suspected. There is no reason why the great majority of these children should not eventually grow up into healthy men and women. All that is required is a little knowledge and a great deal of care."

They are often exceptionally bright and intelligent. There are two open-air schools in use, but more accommodation of this kind is required, and open-air classes in the public parks are recommended. Bristol stands sixth (after the Metropolis) in regard to population among the cities of England and Wales, and appears to be carrying out with thoroughness and efficiency its aim of "raising the standard of health of those children who are to form the future of the race."

BRIGHTON.

At Brighton the health of the 3996 school children who were medically examined in full detail during 1919 was found to be, on the whole, satisfactory. Dr. Duncan Forbes, the school medical officer, gives a useful table in his annual report of the relation of weight to height as a means of estimating nutrition.

"A child who is not up to proper weight for a certain height is more in need of feeding than is the child below both weight and height standard for its age, but of an average height-weight ratio; the latter child is well nourished, and its deficiency in general physique—i.e., its small size—is often due to other causes than improper or insufficient food."

This is perhaps not always recognised. The anthropometric measurements, when compared with those tabulated by Mr. Arthur Greenwood¹ in 1913, are not quite what one would expect to find: the average weight of the 1990 boys was below that of boys in elementary schools in England and Wales generally at each year of age from 3 to 15, except at 5 and 9, when it was above, and at 7 and 10, when it was equal to the average. Among girls the average weight of 2006 was above the general average at 8, 9, 10, 11, and 14; at the other ages it was below the average. On the other hand, the average height was less than that of school children in England and Wales generally only among boys of 3 years and girls of 5 and 8 years; at all other ages the heights were equal to or greater than the general average. The health of the school children generally was satisfactory. Among the 3996 children examined in detail the most numerous defects found were those of vision (151) and throat (tonsils and adenoids 269); no actual tuberculosis of the lung was detected, but 14 children were kept under observation on this account.

URBAN VITAL STATISTICS.

(Week ended August 14th, 1920.)

English and Welsh Towns.—In the 96 English and Welsh towns, with an aggregate civil population estimated at nearly 18 million persons, the annual rate of mortality, which had been 9·8, 9·9, and 9·6 in the three preceding weeks, fell to 9·4 per 1000. In London, with a population of nearly 4½ million persons, the annual death-rate did not exceed 8·5, or 0·6 per 1000 below that recorded in the previous week, while among the remaining towns the rates ranged from 3·9 in Dudley, 4·4 in Hornsey, and 5·1 in Coventry, to 15·2 in Oldham and in Aberdare, 16·1 in Barnsley, and 17·3 in South Shields. The principal epidemic diseases caused 177 deaths, which corresponded to an annual rate of 0·5 per 1000, and comprised 93 from infantile diarrhoea, 40 from diphtheria, 21 from measles, 12 from whooping-cough, 8 from scarlet fever, and 3 from enteric fever. Measles caused a death-rate of 2·2 in Merthyr Tydfil, but the mortality from the remaining diseases showed no marked excess in any of the towns. There were 2106 cases of scarlet fever and 1413 of diphtheria under treatment in the Metropolitan Asylums Hospitals and the London Fever Hospital, against 2027 and 1469 respectively at the end of the previous week. The causes of 30 of the 3226 deaths in the 96 towns were uncertified, of which 7 were registered in Birmingham and 3 each in Coventry, Liverpool, and Barrow-in-Furness.

¹ Health and Physique of School Children, 1913.

Scotch Towns.—In the 16 largest Scotch towns, with an aggregate population estimated at nearly 2½ million persons, the annual rate of mortality, which had been 11·6, 11·2, and 11·1 in the three preceding weeks, rose to 12·3 per 1000. The 297 deaths in Glasgow corresponded to an annual rate of 13·9 per 1000, and included 17 from infantile diarrhoea, 7 from whooping-cough, 5 from small-pox, 2 each from measles and scarlet fever, and 1 from diphtheria. The 74 deaths in Edinburgh were equal to a rate of 11·3 per 1000, but included no death from any of the principal epidemic diseases.

Irish Towns.—The 104 deaths in Dublin corresponded to an annual rate of 13·1, or 0·3 per 1000 below that recorded in the previous week, and included 3 from infantile diarrhoea and 2 from diphtheria. The 107 deaths in Belfast were equal to an annual rate of 13·5 per 1000, and included 2 each from enteric fever and infantile diarrhoea, and 1 from measles.

VITAL STATISTICS OF LONDON DURING JULY, 1920.

In the accompanying table will be found summarised statistics relating to sickness and mortality in the City of London and in each of the metropolitan boroughs. With regard to the notified cases of infectious disease, it appears that the number of persons reported to be suffering from one or other of the ten diseases notified in the table was equal to an annual rate of 6·5 per 1000 of the population, estimated at 4,358,309 persons; in the three preceding months the rates had been 6·7, 6·3, and 6·0 per 1000. Among the metropolitan boroughs the lowest rates from these diseases last month were recorded in Chelsea, the City of Westminster, Hampstead, Holborn, the City of London, and Camberwell; and the highest in Fulham, Finsbury, Bethnal Green, Stepney, and Greenwich. The prevalence of scarlet fever was somewhat greater than in the preceding month; this disease was proportionally most prevalent in Fulham, Bethnal Green, Stepney, Bermondsey, and Greenwich. The Metropolitan Asylums Hospitals contained 1940 scarlet fever patients at the end of the month, against 1795, 1671, and 1674 at the end of the three preceding months; the weekly admissions averaged 234, against 223, 228, and 251 in the three preceding months. Diphtheria was slightly less prevalent than in June; the greatest prevalence of this disease was recorded in Paddington, Fulham, Shoreditch, Bethnal Green, Poplar, and Battersea. The number of diphtheria patients under treatment in

the Metropolitan Asylums Hospitals, which had been 1937, 1783, and 1590 at the end of the three preceding months, further fell to 1470 at the end of July; the weekly admissions averaged 179, against 221, 214, and 189 in the three preceding months. The prevalence of enteric fever was considerably higher than in the preceding month; of the 43 cases notified during the month 6 belonged to Kensington, 6 to St. Marylebone, 4 to Fulham, 3 to Islington, and 3 to Lewisham. There were 24 cases of enteric fever under treatment in the Metropolitan Asylums Hospitals at the end of the month, against 29, 18, and 19 at the end of the three preceding months; the weekly admissions averaged 6, against 4, 3, and 3 in the three preceding months. Erysipelas was proportionally most prevalent in St. Marylebone, Hampstead, Holborn, Finsbury, Bethnal Green, and Southwark. The 10 cases of cerebro-spinal meningitis included 2 in Wandsworth, while of the 7 cases of poliomyelitis 2 belonged to Lambeth.

The mortality statistics in the table relate to the deaths of civilians actually belonging to the several boroughs, the deaths occurring in institutions having been distributed among the boroughs in which the deceased persons had previously resided. During the four weeks ended July 31st the deaths of 3203 London residents were registered, equal to an annual rate of 9·6 per 1000; in the three preceding months the rates had been 15·4, 12·4, and 10·3 per 1000. The death-rates ranged from 6·8 in Hampstead, 7·7 in Fulham, 7·8 in Hammersmith, 7·8 in Woolwich, 8·4 in the City of London, and 8·4 in Wandsworth, to 11·2 in Chelsea, 11·4 in Bermondsey, 11·5 in Poplar, and 11·6 in Shoreditch, in Bethnal Green, and in Stepney. The 3203 deaths from all causes included 192 which were referred to the principal infectious diseases; of these, 34 resulted from measles, 9 from scarlet fever, 44 from diphtheria, 18 from whooping-cough, 4 from enteric fever, and 83 from diarrhoea and enteritis among children under 2 years of age. No death from any of these diseases was recorded last month in Holborn or in the City of London. Among the metropolitan boroughs the lowest death-rates from these diseases were recorded in Hammersmith, Fulham, Hampstead, and Greenwich; and the highest in Kensington, Stoke Newington, and Deptford. The 34 deaths from scarlet fever were 37 below the average in the corresponding period of the five preceding years; this disease was proportionally most prevalent in Kensington, Hammersmith, Hackney, Stepney, Poplar, and Battersea. The 9 fatal cases of scarlet fever were 5 fewer than the

* Including membranous croup.

average. The 44 deaths from diphtheria exceeded the average by 6; the greatest proportional mortality from this disease occurred in Chelsea, Stoke Newington, Southwark, Deptford, and Lewisham. The 18 fatal cases of whooping-cough were 31 below the average; of these deaths, 2 belonged to each of the boroughs of Stepney, Battersea, Wandsworth, and Woolwich. Four deaths from enteric fever were registered during the month, against an average of 7; of these deaths, 2 belonged to Deptford. The 83 fatal cases of infantile diarrhoea were 23 in excess of the average; the greatest proportional mortality from this disease occurred in Kensington, Stoke Newington, Finsbury, Shoreditch, Bethnal Green, and Stepney. In conclusion, it may be stated that the aggregate mortality in London during July from these principal infectious diseases was 19.7 per cent. below the average in the corresponding period of the five preceding years.

The Services.

ROYAL NAVAL MEDICAL SERVICE.

Surg. Cmdr. C. H. Rock is placed on the retired list at own request.
Surg. Lieut.-Cmdr. E. St. G. S. Goodwin is appointed to the *Blake*.

ROYAL ARMY MEDICAL CORPS.

Major and Brevet Lieut.-Col. H. J. Crossley relinquishes the acting rank of Lieutenant-Colonel.
Capt. J. R. Hayman, from Spec. Res., to be Captain.
Temp. Capt. W. D. Arthur, E. J. Mannix, to be Captains.
The undermentioned late Captains, R.A.M.C. Spec. Res., to be temporary Captains: D. B. Robertson, H. A. Hill, W. H. Simmons, D. E. Hearn.
Temp. Capt. M. J. Whelton to be Lieutenant and to be temporary Captain.

Officers relinquishing their commissions:—Temp. Lieut.-Col. J. R. Lord (on ceasing to serve with the Horton War Hospital, and retains the rank of Lieutenant-Colonel); Temp. Capt. W. L. English. Temporary Captains retaining the rank of Captain: J. T. Bleasdel, R. J. Aherne, C. E. Hibbard, L. H. Woods, D. Mitchell.

Overseas Force.

S. T. Mackay and V. B. Ditcham relinquish their commissions on ceasing to be employed as Dental Surgeons and retain the rank of Captain.

TERRITORIAL FORCE.

Major J. W. Bird and Capt. H. Seddon resign their commissions and are granted the rank of Lieutenant-Colonel.
Capt. R. Armstrong and R. C. Neill resign their commissions and are granted the rank of Major.
Capt. A. H. Brewer, A. C. C. Lawrence, and C. C. Lavington resign their commissions and retain the rank of Captain.
1st London General Hospital: Capt. W. B. Ainger resigns his commission and retains the rank of Captain.

TERRITORIAL FORCE RESERVE.

Major C. B. Whitehead, from General List, to be Major.
Capt. W. F. Munro to be Major.
Lieut. H. C. Mee, from North Midland Divisional Train, to be Lieutenant.

ROYAL AIR FORCE.

Flight Lieut. J. H. Porter (Medical) is granted a permanent commission in the rank stated.

INDIAN MEDICAL SERVICE.

The King has approved the grant of the honorary rank of Lieutenant-Colonel in the Indian Medical Service to Dr. Suresh Prasad Sarbadhikari.

The King has approved the retirement of Lieut.-Cols. E. A. W. Hall, F. W. Gee, and W. D. Hayward.

Captains to be temporary Majors: A. F. Babonau, W. M. Lupton, J. B. Lapsley, J. C. Bharucha.

The King has approved the relinquishment of temporary rank by Temp. Capt. Sailendra Nath Chandra and Surapati Ghosh.

PRESENTATION TO DR. W. L. H. DUCKWORTH.

Last week the large theatre of the Cambridge School of Anatomy was the scene of an interesting presentation to Mr. W. L. H. Duckworth, M.A., M.D., D.Sc., senior demonstrator in anatomy, on the completion of 21 years of devoted service to the University as lecturer in physical anthropology. This tribute to the esteem and affection in which he is held was the spontaneous desire of every demonstrator, assistant, and student to contribute to some token of their appreciation of their chief's unfailing courtesy and sympathy, which have made him one of the most approachable and popular of teachers. The presentation took the form of an inscribed silver salver, and was handed to Dr. Duckworth, together with a book containing the signatures of 220 subscribers, by Dr. D. Reid on August 13th in the presence of the staff and students of the anatomy department. In addition to his brilliant academic qualities Dr. Duckworth has shown great capacity for organisation, especially during the past year, when the chair of anatomy has been vacant and the entire control of the anatomy department has devolved upon him.

"Audi alteram partem."

THE TEST FOR OCCULT BLOOD IN THE STOOLS.

To the Editor of THE LANCET.

SIR,—The examination of the stools for occult blood has always the disquieting accompaniment that although a negative result is unequivocal evidence of the absence of blood throughout the alimentary tract, a positive result, especially a comparatively feeble one, introduces the doubt whether an ulcerated lesion of the stomach or intestine is actually present or whether the result may not be due to the fortuitous introduction of hæmoglobin, either from food or from blood itself arising from the naso-pharynx, the mouth, or from hæmorrhoids.

Whilst, however, all clinicians are agreed upon the necessity of eliminating the former possibility by insistence upon a hæmoglobin-free diet for at least three days preceding the test, it does not appear to be a point of universal agreement how far it is possible satisfactorily to exclude all sources of minute hæmorrhages or, from an equally practical standpoint, what degree of such hæmorrhage may be neglected. I am encouraged to raise this question by a statement in Dr. R. Coope's article in your issue of August 7th. He says: "Patients who use hard toothbrushes or who have a habit of sucking their gums often give the reaction for occult blood in the stools." It is, of course, beyond question that the greatest refinement as regards precautions is commendable; and, indeed, in a discussion upon the subject with a well-known chemical pathologist he gave the opinion that the slightest abrasion—even from the passage of an œsophageal tube—would supply sufficient blood to produce a definitely positive reaction in the stools, so sensitive was the benzidine reaction, the test which, like myself, he invariably employed.

My own investigations specifically related to this point certainly do not confirm the idea of an inconveniently exquisite sensitiveness. I lived for a month on a diet free from all hæmoglobin-containing constituents and green vegetables, during which time I ingested measured quantities of my own blood and tested every stool. This investigation was repeated during the war upon a large scale by the administration to patients upon a rigid milk diet of increasing quantities of their own blood. Lieutenant R. M. Mackay, R.A.M.C., working under my directions, embodied the results in a thesis for M.D. Edin., but I do not think the thesis was ever widely circulated, if published at all. The conclusion was that not until 1 c.cm. blood at one dose was taken could we be certain of a positive reaction. One cannot say, of course, if the more frequent ingestion of tiny quantities throughout the day would more easily lead to a positive result—the question of absorption is an important one—but certainly a cubic centimetre of blood is a fairly considerable quantity, and I am prompted to inquire if Dr. Coope or any other observer is really satisfied as the result of crucial tests that small gum abrasions alone have been responsible for a positive result.

I ought to add that whilst these tests were in operation the reagents were regularly tested and results controlled by the use of a solution of blood, whereby it was certain that even up to a dilution of 1 in 300,000 a marked positive reaction was obtained. The circumstance, then, of a negative reaction being possible when as much as $\frac{1}{3}$ c.cm. of blood has been introduced into the stomach hardly suggests that the benzidine test is "too sensitive"; nor, may I add, have I found it unreliable if all precautions with the reagents are taken; whilst its simplicity is a feature which must always make a strong appeal.

I am, Sir, yours faithfully,

ADOLPHE ABRAHAMS.

Park-crescent, Portland-place, W., August 14th, 1920.

FOOD POISONING FROM PARATYPHOID B INFECTION.

To the Editor of THE LANCET.

SIR,—Your annotation last week on the Carrier in Food Poisoning leads me to put on record the following case on account of the importance of bacteriological examination:—

I was called to see J. B., aged 59, on July 19th, suffering from severe diarrhoea and vomiting. Temp. 100° and pulse corresponding. Foul, coated tongue, but no abdominal pain beyond that caused by retching. Physical examination negative except for slight tenderness over stomach and descending colon. Normally a man with systolic pressure bordering on 200 mm. Hg. and therefore frugal in diet. Had retired to rest on previous evening feeling well, but was awakened at 4 A.M. with violent diarrhoea and sickness. He had had his usual diet with the exception of a small piece of cold sausage, which naturally fell under suspicion, but as the rest of the family had partaken of the same food without untoward results no food analysis was undertaken. The vomited matter appeared to be bile and the stools were liquid and almost milky in appearance. The following day he had 11 fluid evacuations during the 24 hours, still the same colour and very offensive. An injection of emetine hydrochlor., gr. $\frac{1}{2}$, was given and digalen hypodermically. That evening he seemed better, temp. 98°, pulse stronger, no evacuation of the bowels for four hours. Next morning diarrhoea was constant and the patient in a condition of profound collapse, temp. 95°, pulse almost imperceptible at the wrist, knee-jerks and plantar reflex absent.

Dr. W. H. Willcox was called in consultation and a specimen of faeces was sent to Dr. E. J. Storer, Inoculation Department, St. Mary's Hospital, who reported as follows:—

Macroscopically: Milk-like fluid.

Microscopically: I found debris, few pus cells.

Culturally: Many non-lactose fermenting organisms giving the sugar reactions of the *Solmonella* group.

Morphologically: Gram-negative motile bacilli; serological reaction. Agglutination: Gaertner serum, 1/20; *B. para. A*, 1/20; *B. para. B*, 1/320; *B. aertrycke*, 1/32.

Sera absorbed with organisms: *B. para. B* serum, 1/25; *B. aertrycke*, 1/160; *B. botulinus* not isolated.

Conclusion: *B. para. B* infection.

A specimen of blood sent to Dr. Knyvett Gordon was returned "paratyphoid B positive in a dilution of 1 in 100."

Energetic stimulant measures were taken, salines were injected freely, oxygen inhalations through spirit, and pituitrin hypodermically. Patient remained gravely ill, with subnormal temperature, weak intermittent pulse, and four or five fluid evacuations a day until the 25th, when his temperature rose to 98° and he had only one semi-solid stool, less offensive and almost normal in colour. Since then his condition has steadily improved.

I had a similar case of paratyphoid B infection with much milder symptoms two months ago in a young adult. In this case there came under suspicion a veal pie, partaken for luncheon at his golf club, and yet on inquiry others who had lunched with him suffered no ill-effects. In the third week he developed a left-sided pleural effusion. These cases must be more common than one is led to believe, and in view of the evidence given by Dr. J. Priestley in the cases that occurred in London recently, the after-care of such patients is of the utmost importance.

I am, Sir, yours faithfully,

W. J. MCKEAND, M.B., Ch.B. Edin.

Compton-terrace, N., August 17th, 1920.

HERPES AND CHICKEN-POX.

To the Editor of THE LANCET.

SIR,—I have read Dr. Claude Ker's paper on Herpes and Chicken-pox in your issue of August 14th with interest. A number of instances of the supposed association of the two conditions have been recorded in *Guy's Hospital Gazette* in the last few years. One enthusiast even went so far as to record that, having diagnosed herpes in a parent, he prophesied successfully that the children would develop chicken-pox. I do not doubt his word; but it is difficult to weigh the evidence of all prophecy, because there are no records of the false ones. I have seen many cases of both diseases

without finding any evidence to connect them, except for one patient with typical herpes zoster and a rash indistinguishable from chicken-pox, both present at the same time. The notes were recorded in the above-named gazette. However, there is enough evidence of a possible connexion to make the subject an interesting study; and more figures are needed, as Dr. Ker suggests, which will deal with all cases and not lay undue emphasis on the exceptional ones.

There are two points which he does not discuss which might be emphasised. First, from the clinical point of view, is the question of pain; it is a very constant symptom in herpes zoster, and of real practical importance in justifying the diagnosis of herpes if an unusual distribution of chicken-pox were under discussion. The second, much more important and apparently not generally known, is that the cerebro-spinal fluid in herpes zoster shows a marked excess of lymphocytes; several times I have found more than 100 per c.mm. (more than five may be taken as abnormal). The fluid must be examined early, as the lymphocytes soon subside.

I do not know whether any observations of the cerebro-spinal fluid have been made in chicken-pox, but it seems to me that this examination is likely to prove the most important single piece of evidence towards joining or separating the two diseases.

I am, Sir, yours faithfully,

Derby, August 17th, 1920.

HUGH BARBER.

Obituary.

SINCLAIR WHITE, C.B.E., M.D.R.U.I., F.R.C.S.ENG.

LIEUTENANT-COLONEL, R.A.M.C.; LATE PROFESSOR OF SURGERY, UNIVERSITY OF SHEFFIELD.

BY the death of Sinclair White Sheffield loses one who has been a prominent figure in medical circles for many years, and latterly has taken a leading part in the affairs of the profession. His early death so soon after retiring from active practice, to enjoy the leisure for which he had worked so hard, is deeply regretted by a wide circle of colleagues and friends. Nearly 40 years ago he went to Sheffield, a stranger, unknown to anybody in the district; there he spent the whole of his active life. A year ago on his retirement his name as a great surgeon was a household word for many miles around, and the calls upon his services were more numerous than he could fulfil.

The story of his life is the old story of what a man can do by his own efforts provided he has brains, courage, and determination. Born in 1858 and graduating in 1879 after a brilliant career as a student at Queen's College, Galway, fate brought him for his first appointment to the Sheffield School of Medicine in the humble capacity of so-called "tutor." Coming as a complete stranger, the first impressions which he received of his new post and its duties could not have been very inviting. The School of Medicine was at that time about at its lowest ebb. Other schools had begun to develop on new lines, but for some years the medical school in Surrey-street remained as an example of the old medical schools of the period which Dickens described. Dark and dismal, it consisted of an anatomical theatre upstairs, leading out of a dissecting room with sawdust on the floor and an appearance of something between a stable and a dirty butcher's shop; whilst downstairs there was a musty old library and a so-called students' room in which the porter also prepared "bone specimens." In this room the students spent much of their time sitting round the fire, smoking. It was not exactly a healthy atmosphere. The "tutor" was the only paid teacher, and his duties included taking charge of the dissecting room, holding tutorial classes in anatomy and physiology, and generally superintending everything. For these varied functions a stipend of £100 per annum was paid. In the case of many men such surroundings would have either frightened them away or broken their spirit, but White was not of that kind. He set to work to make the best of it, and in helping the students helped himself to get the Primary Fellowship.

In course of time he became a resident at the Public Hospital and Dispensary (now the Royal Hospital), and, whilst there, took his Final Fellowship in 1884. His ability and energy soon brought him into favourable notice with the board and the staff, so that on completing his period of service he had no difficulty in getting recommended for the post of medical officer of health of Sheffield, which was then vacant. He entered upon the duties of his new post with vigour and zeal, and soon proved himself a public servant of exceptional value to the corporation. Of his work in that capacity deserve particular mention his important and fruitful researches upon "The Action of the Sheffield Water on Lead Piping and its Effects on the Health of the Community." The results of this work were of immediate practical value, and brought about a complete cessation of lead poisoning from water in the district. Apart from its technical side, there is no doubt that the tenure of this post afforded him many and varied experiences of business methods and general knowledge of all kinds which proved of value in his later career. It is obvious, however, that even at this stage of his life his aim was to become an operating surgeon, and that he was only holding the post of medical officer of health in order to keep going until opportunity offered itself.

After a few years he resigned this post to take up general practice in the west-end. His first surgical appointment was in connexion with the Sheffield Hospital for Sick Children, which was followed in the early "nineties" by his appointment to the Royal Hospital. Up to this time he continued his general practice, and it is probable that the amount of operative surgery which he obtained outside his hospital duties was not very great. It was not until a few years later that the real opportunity for which he had been waiting and preparing himself arose. A series of vacancies amongst the senior members of the Royal Infirmary staff having arisen rather rapidly, White was invited to join the staff as surgeon. From that time onwards his career as an operating surgeon progressed by rapid strides, and for many years, practically up to the time of his retirement, his surgical life was an extremely full one. Few men worked harder or spared themselves less. As a surgeon he was undoubtedly a master of his craft, with a sound and ripe judgment, courageous and resourceful, untiring and undismayed by difficulties. Outside his own wide sphere of operations, he was less well known than he deserved to be, and his name was less familiar than that of many whose ability was no greater. This is easily explained by the circumstances of his career. During the "writing" period of his life he had not the surgical opportunities; when the surgical experience offered itself he was too busy to write! Such few surgical writings as he published were all valuable contributions to practical knowledge, but he was not a writing man.

His connexion with teaching, which began as tutor at the medical school, was kept up almost without intermission, and culminated in the professorship of surgery, accepted in 1911, which he resigned only two years ago. As a lecturer he was not at his best. Speaking in public was always distasteful to him. He did not cultivate it, and anything in the nature of lecturing was an effort. In medical affairs, both local and general, he was deeply interested and took an active part, being secretary of the British Medical Association when it visited Sheffield in 1908, and later, on the death of the President (Professor Simeon Snell), occupying the presidential chair for the remainder of the year. He also held the posts of President of the Sheffield Medico-Chirurgical Society and of the Yorkshire Branch of the B.M.A. During the war his services in connexion with the 3rd Northern General Hospital were very strenuous. His work as medical officer in charge of the surgical department, and later as officer in charge of the hospital, undoubtedly hastened the breakdown which ended his life. Even before the armistice his health broke down, and a somewhat serious operation left him very much shaken. For his military services he was made a Commander of the British Empire.

Of his personality it is somewhat difficult to speak, for he was a reserved man really known only to very few. His manner was somewhat brusque and the kindness which lay behind it was not always allowed to be seen. Those, however, who had the privilege of really knowing him, whether as colleagues, patients, or personal friends, realised that there was a kind heart behind the outward manner, and that in all things he was generous, straightforward, and conscientious.

JAMES HERBERT RHODES, M.B. LOND., M.R.C.P.

Dr. J. H. Rhodes, who died in London on August 5th after a long and trying illness suffered with excellent fortitude, was born at Kendal in 1874. He took his medical course at St. Bartholomew's Hospital, qualifying in 1899, and becoming house physician to Sir Lauder Brunton, with whom he conducted a research on the presence of glycolytic ferment in muscle. Brunton then expressed his appreciation of the powers of keen insight along with patient and persevering work shown by his junior colleague. After four years as senior resident medical officer at the London Temperance Hospital Dr. Rhodes became officer in charge of the electrical department there and honorary physician to the Farringdon General Dispensary and Lying-in Charity. He was also consulting radiographer to the Royal Eye Hospital. Unfitted by his health for service abroad, Dr. Rhodes during the war was medical officer in charge of the Queen's Gate Red Cross Hospital and the electrical department at Lewisham Military Hospital.

In October, 1914, however, hearing that there was no X ray outfit in working order at Boulogne or its neighbourhood, he went out on behalf of the British Red Cross Society to see what he could do, taking with him two outfits and finding in seven hospitals either no apparatus or the apparatus unworkable. He was happy to see five hospitals fitted up with X ray apparatus in working order within a month and arrangements made in regard to two others. Since 1904 he had been in practice in South Kensington, latterly being occupied largely with the practice of artificial pneumothorax, in which he was specially interested.

One of his professional colleagues writes: Rhodes was undoubtedly one of the best types of general practitioner. An all-round knowledge of the scientific sides of medicine and surgery combined with an expert equipment in electrical work and in tuberculosis, these were only one side of his qualifications. On the other was a conscientiousness which refused to allow him to spare himself. With him the interest of the patient came before everything else, and this fact was so patent that it earned for him in no ordinary degree the affectionate regard of those who came under his care. Scrupulously sensitive in his relations with brother practitioners, he kept the spirit as well as the letter of a lofty ethical code. Thorough and painstaking, he was also modest and self-effacing to a degree, but with better health he would have attained great success as a London general practitioner.

JAMES KING KERR, M.D. Q.U.I., J.P.

Dr. Kerr, who died on August 10th at Belfast in his seventy-fifth year, was well known as a medical practitioner and esteemed as a citizen. He had long been suffering from diabetes, but continued to take an active part in public affairs. A native of county Antrim, he was born near Randalstown, studied at the Royal Academical Institution and at Queen's College, Belfast, graduating M.D. of the old Queen's University of Ireland in 1871. He then acquired a practice at Leytonstone, remaining there until his health broke down from overwork, when, after a voyage to China, he settled in practice at Knock, in the suburbs of Belfast. His public life began by unsuccessfully contesting a Parliamentary seat in county Antrim in 1900 as an independent Conservative. He entered the Belfast Corporation, where he rose to be an alderman and, in 1904, chairman of the Public Health Committee, and subsequently he became chairman of the Hospitals and Dispensaries Committee. He was a justice of the peace for Belfast and a governor of Campbell College. He is survived by a widow.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

MINISTRY OF HEALTH (MISCELLANEOUS PROVISIONS) BILL.

SOME highly important questions of medical interest are dealt with in the Ministry of Health (Miscellaneous Provisions) Bill, which Dr. ADDISON, the Minister of Health, presented in the House of Commons on Monday, August 16th.

Incipient Mental Disorder.

Clause 10 relates to treatment for incipient mental disorder. It sets out that—

"(1) Notwithstanding the provisions of any Act, a person shall not, if the required conditions are complied with, be liable to any penalty for receiving to board, lodging, or taking charge of for a period not exceeding six months, or such longer period not exceeding in all 12 months, as may be approved by the Minister, and whether for payment or not, any person suffering from mental disorder which is incipient in character and of recent origin, but not being a person who has been certified as a lunatic under the Lunacy Acts, 1890 to 1911, or in respect of whom an order has been made under the Mental Deficiency Act, 1913. Provided that nothing in this section shall authorise any person who has been received into any institution, home, or house under this section to be detained therein if he delivers to the superintendent or other person, by whatever name called, having the charge of the institution, home, or house, or sends by post to the Minister, notice in writing that he desires to be discharged therefrom.

(2) The required conditions for the purposes of this section are as follows: (a) The institution, home, or house in which the person is received must be approved for the purposes of this section by the Minister. (b) No such person shall be received into the institution, home, or house except with his previous consent in writing and except on a certificate in writing by two duly qualified medical practitioners to the effect that that person is reasonably likely to benefit by treatment therein. (c) The superintendent or other person, by whatever name called, having charge of the institution, home, or house, shall on the demand of any person having authority to inspect the institution, home, or house produce all such written consents and certificates as aforesaid. (d) The reception under this section of any person into the institution, home, or house shall be reported to the Minister by the superintendent or other person aforesaid.

(3) Any institution, home, or house approved by the Minister under this section shall be periodically inspected by officers appointed for that purpose by the Minister.

(4) The Minister may make regulations for the purpose of carrying this section into effect."

The maximum penalty for a contravention of the section is a fine of £100 or imprisonment for six months, or both fine and imprisonment.

Hospitals on the Rates.

Clause 11 confers on county councils the power to provide hospitals and ambulances. The main part of the clause is in the following terms:—

"(1) The council of a county shall have power (a) to supply and maintain hospitals (including out-patient departments) for the treatment of illnesses and diseases generally, or for the treatment of any particular illness or disease, or any particular class of illnesses or diseases; and (b) to contribute, on such terms and conditions as may be approved by the Minister, to any voluntary hospitals or similar institutions within their area; and (c) to undertake the maintenance of any Poor-law hospitals or infirmaries within their area; and (d) to establish and maintain, or to contribute towards the cost of or otherwise aid in establishing or maintaining, an ambulance service for dealing with cases of accident or illness within their area.

(2) The councils of two or more counties may, with the consent of the Minister and subject to such conditions as he may prescribe, combine for the purposes of supplying and maintaining hospitals under this section, and where any councils so combine they may appoint a joint committee under Section 81 of the Local Government Act, 1888, and that section shall have effect accordingly.

(3) Section 132 of the Public Health Act, 1875 (which gives powers to recover the cost of the maintenance in hospital of a person who is not a pauper), shall apply to any patient who has received treatment in a hospital maintained by the council of a county under this section, and the council shall have the same power of recovering expenses as is given to a local authority under that section."

The expression "council of a county" includes the council of a county borough.

Clause 12 lays down that no person shall sell, supply, or deliver any clinical thermometer unless it has been tested,

approved, and marked in accordance with regulations made by the Minister.

Certain amendments are proposed in enactments relating to the sale of food and drugs.

Clause 14 permits a port sanitary authority, with the approval of a Secretary of State and of the Minister, to authorise the medical officer of health of the authority to perform any duties in connexion with the medical inspection of aliens landing or desiring to land within the area.

HOUSE OF LORDS.

TUESDAY, AUGUST 10TH.

Dangerous Drugs Bill.

The Dangerous Drugs Bill was read a third time and passed.

WEDNESDAY, AUGUST 11TH.

Blind Persons Bill.

The Blind Persons Bill was read a third time and passed.

HOUSE OF COMMONS.

WEDNESDAY, AUGUST 11TH.

National Health Insurance Valuation.

Mr. CAUTLEY asked the Minister of Health if he would state when the valuation of the National Health Insurance Societies was likely to be completed.—Dr. ADDISON replied: The separate valuation of each of the 12,000 Approved Societies and branches which administer National Health Insurance is a task of immense magnitude. The work is being proceeded with under the supervision of the Government actuary, and very satisfactory progress is being made, but it will be some months before a general announcement of the results can be made.—Mr. CAUTLEY: Is it not possible to give some approximate date?—Dr. ADDISON: I am afraid it will not be before the end of the year at the earliest.

A Standard for Condensed Milk.

Mr. GRATTAN DOYLE asked the Minister of Health if he could now state what progress had been made by the committee set up to inquire into the determination of a standard for condensed milk; if he would take immediate steps to prevent the importation or manufacture of condensed milk with low standards of fat, to the great detriment of the consumer; if the committee had yet reported; and, if not, if he would state the reasons for the delay.—Dr. ADDISON replied: I understand that the committee hope to present their report to me very shortly. The matter will then have my careful attention.—Mr. HOWARD GRITTEN: May I ask when the right honourable gentleman proposes to proceed with the Milk and Dairies Bill, and whether there is not a good deal of opposition to it in the country?—Dr. ADDISON: I am aware that there is considerable interested opposition to one clause. We certainly hope to proceed with the Bill at the first possible opportunity.

Third London General Hospital, Wandsworth.

Mr. CLYNES asked the Minister of Health whether he could make any statement as to the present position regarding the Third London General Hospital, Wandsworth.—Dr. ADDISON replied: I have made every effort to secure the retention of this hospital for the use of the civilian population, but I have ascertained that the site of the hospital is held by the London County Council on trust for the purpose of an open space; that it was acquired by them before the war for that purpose from the Royal Patriotic Fund Corporation at less than market value in consideration of the use to which it was to be put; and that the Royal Patriotic Fund Corporation object to its use for a civilian hospital, and urge that the conditions on which the land was sold must be adhered to. Moreover, I understand that part of the price paid for the land was subscribed locally and that there is strong opposition to the land being diverted from use by the public as an open space. I am advised that legislation would be necessary in order to secure the retention of the hospital on its present site, and in the circumstances I do not think that Parliament would be willing to give the necessary powers. I have therefore regretfully come to the conclusion that I must abandon my efforts to obtain the use of the hospital on its present site for the civilian population.

Ventilation of Factories, Schools, and Coal-mines.

Major Sir KEITH FRASER asked the Minister of Health if he would take steps to improve the ventilation of the factories and schools in Leicestershire with a view of checking the increase of tuberculosis in that area; and would he consider a better system of ventilating the coal-mining levels than that which existed at present.—Dr. ADDISON replied: The number of notifications of tuberculosis in Leicestershire has diminished from 524 in 1914 to 364 in 1919. I am glad to state that this decrease is general throughout the country, the corresponding figures for England and Wales being 95,808 in 1914 and 74,647 in 1919. Questions as to the ventila-

tion of factories and coal-mining levels and of schools should be addressed to my right honourable friends the Home Secretary and the President of the Board of Education respectively.

Poor-law Reform Promised.

Mr. GILBERT asked the Minister of Health whether the Government proposed to bring in any legislation during the present Parliament dealing with the reform of the Poor-law and in any way altering the composition of the bodies which now administered the existing laws.—Dr. ADDISON replied in the affirmative.

Injurious Foreign Potable Spirits.

Colonel GRETTON asked the Minister of Health if he was aware that many complaints and allegations had been made of the bad quality and injurious results arising from the consumption of certain imported potable spirits; if the Ministry had taken any steps to test the truth or otherwise of such statements; if the Ministry had powers under the Food and Drugs Act to condemn imported potable spirits of bad quality; and, if so, had such powers ever been used.—Dr. ADDISON replied: Inquiries have been instituted into the allegations referred to, and I should be happy to consider any specific information in the honourable and gallant Member's possession. Under the Sale of Food and Drugs Acts the vendor of any article of food or drink which is either injurious to health or not of the nature, substance, and quality demanded is liable to prosecution. The Acts are administered by local authorities, and the Ministry of Health have no powers of condemnation.

A Hardship to Limbless Officers.

Colonel GREIG asked the Minister of Pensions whether, owing to the hardship caused by Army Council Instruction 326, of 1920, 2 (a), to limbless officers whose stumps were not sufficiently healed for an artificial leg or arm to be fitted in the time therein allowed, he would specially supplement their disability pensions until such limbs were fitted, so that it might amount to as much as their Service pay.—Major TRYON (Parliamentary Secretary to the Ministry of Pensions) replied: When an officer, who has been demobilised, is waiting to be fitted with an artificial limb and is unable to provide for his own support he may be granted, from the Ministry, disability retired pay at the maximum rate during the waiting period, and I have no authority to make any larger allowances.

Inferior Drugs and Dressings in India.

Mr. SPOOR asked the Secretary of State for India whether his attention had been drawn to the circular letter issued on Sept. 15th, 1919, by the Government of India (Indian Munitions Board) to the various local governments and administrations in India concerning the drugs and surgical dressings required by the forces in the field supplied to Government by a firm of chemists in Bombay, and stating that the drugs were so adulterated and the dressings so medicated and otherwise below the represented quality as to imperil the lives of soldiers; that this was done deliberately by the firm in question to swell its own profits; that the name of the firm had therefore been removed from the Government of India list of contractors, and recommending that it should be removed from the lists of contractors to the provincial governments; whether, in communicating this information to the public through the press, the name of the firm in question was suppressed and was still being withheld, and why; whether he would communicate the name of this firm to the House and explain the reasons of the Government of India for their failure to prosecute the directors or managing directors, or both; and whether he would direct that such prosecution should take place.—Mr. MONTAGU replied: I have no information on the matter to which the honourable Member refers, but I will inquire.

MONDAY, AUGUST 16TH.

Travelling Facilities to Men under Treatment.

Colonel ASHLEY asked the Minister of Pensions whether any facilities could be given to wives to visit their husbands while undergoing treatment away from home when the treatment was prolonged and the man's condition prevented him travelling; and whether, in view of the hardship otherwise involved, he would consider the question of granting such facilities.—Major TRYON replied: Under the present regulations of the Ministry a man undergoing treatment in an institution away from home may be provided with a half-fare railway ticket to enable him to visit his home after each three months' treatment, or alternatively with a full-fare ticket after each six months' treatment. I am satisfied that there is hardship where a married man is not sufficiently convalescent to visit his home, and is therefore debarred from benefiting by the concession. I am glad to be able to say that arrangements have now been sanctioned under which the free travelling privileges now granted to the man during treatment in an institution can, in future, be transferred to his wife when the husband's condition does not admit of his travelling home.

The London University Site.

Mr. GILBERT asked the Chancellor of the Exchequer whether, having regard to the fact that the Government did not propose to proceed with the purchase of the Bloomsbury site for the University of London unless and until the University accepted the offer, and having regard to the report of the valuer of the London County Council as to the relative value of certain sites and the present inability of the Government to offer any contribution towards the erection of the required buildings on the Bloomsbury site, he would hold over the purchase money for the site to be devoted to such purposes, subject to the approval of the Government, as the Senate of the University might recommend as most serviceable for the recognised object of the University, and for the furtherance of university education in London as the metropolis of the British Empire.—Mr. BALDWIN (Financial Secretary to the Treasury) replied: No, Sir. For the reasons which I gave on Tuesday last the offer of the Government relates only to the Bloomsbury site.

Facilities for Transfer to Ordinary Hospitals.

Mr. BRIANT asked the Secretary for the Home Department whether he would consider the desirability of further facilities for the transfer of sick prisoners to ordinary hospitals.—Mr. SHORTT replied: The powers which already exist and are very freely used for the transfer of sick prisoners to ordinary hospitals are found to be sufficient for the purpose.

Third London General Hospital, Wandsworth.

Colonel Sir GODFREY COLLINS asked the Secretary for War if he could state the approximate cost of the Third London General Hospital, Wandsworth; and would he say if this hospital was to be broken up or transferred to either the Ministry of Health or a local authority.—Sir A. WILLIAMSON (Financial Secretary to the War Office) replied: The Third London General Hospital consisted of the Royal Victoria Patriotic School buildings and grounds and a hutted portion on the common adjoining the school. Approximately £69,000 was spent on the hutted portion. During 1919 the school buildings and grounds were surrendered and the hospital concentrated in the hutted portion on the common. The hospital was closed on July 31st last, and is being reported to the Disposal Board as surplus to military requirements. With regard to the latter part of the question I would refer the honourable and gallant Member to the reply given by my right honourable friend the Minister of Health to a similar question asked by the right honourable Member for Plating on Wednesday last.

Protection of Mentally Defective Persons Bill.

Mr. WIGNALL presented a Bill to make further provision for the protection of lunatics, idiots, and imbeciles, and other mentally defective persons from sexual immorality and from conduct akin thereto or connected therewith; and for purposes relating to the matters aforesaid. The Bill was read a first time.

Medical News.

KING'S COLLEGE (UNIVERSITY OF LONDON): PUBLIC HEALTH DEPARTMENT.—At King's College the department of Public Health, recently reorganised under the general supervision of Professor W. J. R. Simpson, now offers complete courses of instruction for the various special degrees and diplomas. Lectures are delivered on hygiene, sanitary law and administration, sanitation, and vital statistics by Dr. D. Sommerville, and on the Food and Drugs Acts by Mr. Rhys Charles. Bacteriology and parasitology are taught by Professor R. T. Hewlett and Dr. F. E. Taylor, and the chemical laboratory work is in charge of Mr. William Partridge. The laboratories are open daily for instruction and research, and arrangements have been made to suit the convenience of those engaged in practice. Weekly demonstrations on sanitary appliances and visits to places of sanitary interest are arranged. A special course on industrial hygiene will be given by Dr. T. M. Legge (October to February), and on school hygiene by Dr. A. J. Malcolm (October to June).

AMALGAMATION OF THE BRISTOL HOSPITALS.—The Bristol General Hospital committee has signified its willingness to enter, on certain conditions, into an amalgamation with other voluntary medical institutions of the city for a period of three years. As has already been stated in THE LANCET, this committee could not see its way to an irrevocable surrender of its trust to a newly constituted comprehensive council, but it considers a trial of three years feasible on condition that its present assets are not pooled with those of the other hospitals, and that the hospital remains a general hospital.

WHITE CLIFF HOSPITAL, TORQUAY.—The Western Hospital, Torquay, was established in 1850 for the treatment of incipient consumption and was supported by voluntary contributions. During the war it was used for the treatment of tuberculous soldiers, and has recently been purchased by the Devon County Council. It will be known in the future as the "White Cliff," and will be used for the treatment of tuberculous patients.

THE LATE DR. R. G. FENDICK.—Robert George Fendick, late senior surgeon to the Bristol Dispensary, died recently at Eastbourne in his seventy-fifth year. A son of the late Mr. J. Fendick, M.R.C.S., of Bristol, Dr. Fendick was educated at Bristol Medical School, qualified M.R.C.S. in 1867, and practised for many years in Bristol and Clifton, where he was highly esteemed.

DORSET MENTAL HOSPITAL.—Dr. G. E. Peachell, the medical superintendent of this hospital, in his annual report for 1919 states that the institution now accommodates 541 patients from the county of Dorset, 95 from out-county unions, 22 service patients, and 233 private patients. No other county mental hospital has so large a number of private cases, which were very beneficial for the county rates. In alluding to the chief causes of insanity amongst the patients, Dr. Peachell mentions that he has been struck with the few cases in which alcohol appeared to be a factor.

ROYAL CORNWALL INFIRMARY, TRURO.—The medical report presented at the annual meeting of this institution showed that 711 in-patients and 1459 out-patients had been treated. The expenditure was £5947 and the total deficit against the infirmary up to last May was £419. The chairman, Canon Graves, urged the advisability of making a charge to those patients who were able to pay, and the matter was recommended to the governors for consideration. A tender for £13,819 for the renovation and enlargement scheme had been accepted and the work was now proceeding. £9800 had been received in response to the appeal for this purpose, but it is estimated that a sum of £15,000 will be required to meet the total cost.

ROYAL DEVON AND EXETER HOSPITAL.—At a recent meeting of the governors of this hospital it was reported that the cost of the new Victory wing which is to be added to this institution will be about £40,000, towards which £24,000 have been raised. The governors considered that for the better accommodation of the nursing staff it would be advisable to build a second storey on to the Victory wing, at an estimated cost of about £12,000, and this was agreed to by the meeting. It was stated that the patients will have to make contributions towards their cost of maintenance, and a special meeting will be held to consider this question. The president, General Stirling, said that the question of the amalgamation of the hospital with the Exeter Dispensary had been carefully considered, but it was decided that such a scheme was not feasible.

ROYAL MEDICAL BENEVOLENT FUND.—At the last meeting of the committee, held on August 10th, 22 cases were considered, and £244 11s. 1d. voted to 20 of the applicants. The following is a summary of some of the cases relieved:—

* L.S.A. Lond., aged 63, married, who for some years has acted as locum tenens. Has recently completely broken down in health, and is suffering from tabes dorsalis and is in Guy's Hospital. Last year only earned £121. Rent £32 10s., and wife lets an unfurnished room at £11 4s. Friends have given £10. No prospect of applicant being able to work again, and they are practically destitute. Voted £26 in 12 instalments. —Daughter, aged 62, of M.R.C.S. Eng. who practised at Bradford, Yorks, and died in 1903. Owing to nervous breakdown applicant has been for some time in a nursing home. Is now staying with friends, who will be unable to keep her. Income £50 from investments. Desirous of getting into a home. Voted £12 in 12 instalments. —Wife, aged 46, of F.R.C.S. Irel. who practised in London. Owing to overwork during the war and financial worry applicant's husband is now completely incapacitated, and it is not expected that he will be able to work again. Three children, aged 23, 20, 10. The eldest, a daughter, earns £3 a week. The son, aged 20, is going to Australia. Rent £115, for 11-roomed house, the lease of which runs out in September, when £300 will be required for dilapidations. A friend has lent the money to pay the rent up to September. Desirous of getting a house and letting rooms, and asks for help to make a start and towards the youngest son's education. Voted £10. —Daughter, aged 56, of M.R.C.S. Eng. who practised at Box and died in 1894. Suffers from ill-health, and is unable to earn anything. Shares everything with her two sisters, one of whom has help from the Fund. Relieved ten times, £132. Voted £12 in 12 instalments. —Daughter, aged 61, of M.R.C.S. Eng. who practised at Leatherhead and died in 1861. Until recently has acted as school matron at £30 a year, but is at present out of employment, and, owing to her age, finds it difficult to obtain another post. Is at present staying with friends. Has no income but that which she earns. Relieved once, £10. Voted £5.

Subscriptions may be sent to the honorary treasurer, Sir Charters J. Symonds, at 11, Chandos-street, Cavendish-square, London, W.1.

ROYAL SANITARY INSTITUTE.—The next Congress of the Royal Sanitary Institute will be held at Folkestone in June, 1921.

THE Wellcome Historical Medical Museum, at 54A, Wigmore-street, London, W., will be closed for cleaning and decoration from Sept. 1st to 30th.

THE LATE DR. C. W. VICKERS.—Charles William Vickers died at Paignton, Devon, on August 1st, in his seventy-third year. Dr. Vickers received his medical education at King's College Hospital and the London Hospital, and after qualifying M.R.C.S. in 1870, practised for a time in London, and came to Paignton for the benefit of his health in 1883. He took his D.P.H. in 1896 and was for 29 years medical officer of health for Paignton. Dr. Vickers was a painstaking medical officer of health, and his work was much appreciated by the residents of Paignton until his recent retirement. About 20 years ago small-pox occurred amongst the men working on the construction of the waterworks, and his energetic methods prevented any spread of the disease. Dr. Vickers leaves a widow and one son.

TECHNICAL PHARMACY.—Courses are now instituted in technical schools to prepare students for the examinations of the Pharmaceutical Society, and the Pharmaceutical Society of Great Britain has decided to divide its qualifying examination into two parts. The subjects of Part I. are Chemistry, Botany, and Physics, and the subjects of Part II., Pharmacy, Materia Medica, and other technical subjects. The society will henceforth require that students who offer themselves for the qualifying examination shall have pursued an approved course of study in an institution approved by the society. A circular from the Board of Education to local educational authorities as well as technical schools points out that the Board is informed that the society recognises and approves, for the purposes of Part I. of its examination, all those institutions which are already recognised by the General Medical Council. Special considerations, however, arise in connexion with Part II. of the examination. The efficient teaching of the subjects of this part of the examination entails considerable expenditure on equipment and stores, and for certain subjects the appointment of a specially qualified teacher. The Board understands that the society has approved courses preparing for Part II. of its examination in nine technical schools and colleges in various parts of the country, and that in these institutions alone provision can be made for 700 students, a number which is largely in excess of the number who annually qualified in pharmacy before the war. In these circumstances the Board does not propose to recognise, under its regulations, any course in the subjects of Part II. of the Pharmaceutical Society's Qualifying Examination, unless the Pharmaceutical Society has previously approved the course for its own purposes.

Appointments.

Successful applicants for vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to THE LANCET Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.

- BURROUGHS, A. E., M.D. Edin., has been appointed Specialist Medical Referee for Ophthalmic Cases under the Workmen's Compensation Act, 1906, for County Court Circuit No. 6.
- St. Thomas's Hospital: HUMPHREYS, R. M., M.B., B.Ch. Oxon., Whitcombe, R. C. P., M.R.C.S., L.R.C.P. Lond., KENDALL, G. M., M.B. Cantab., GARNETT, D. G., M.R.C.S., L.R.C.P. Lond., WONG, M., M.R.C.S., L.R.C.P. Lond., D.T.M., MAXWELL, L. B., M.R.C.S., L.R.C.P. Lond., Low, W. A., M.R.C.S., L.R.C.P. Lond., Casualty Officers and Resident Anaesthetists; HOBBS, F. B., M.R.C.S., L.R.C.P. Lond., BLAMPIED, H. J., M.R.C.S., L.R.C.P. Lond., ORME, E. S., M.R.C.S., L.R.C.P. Lond., BRETT, P. C., M.R.C.S., L.R.C.P. Lond., Resident House Physicians; WARE, S. A. T., M.R.C.S., L.R.C.P. Lond., Resident House Physician for Children; CHURCHER, D. G., M.B., B.S. Lond., SMART, A. H. J., M.B., B.Ch. Cantab., NEILSON, D. F. A., M.R.C.S., L.R.C.P. Lond., BROCKMAN, E. P., M.B., B.Ch. Cantab., Resident House Surgeons; MARRINER, H. I., M.R.C.S., L.R.C.P. Lond., Resident House Surgeon for Ear, Nose, and Throat; ROBINSON, R. H. O. B., M.B., B.Ch. Cantab., House Surgeon; COOKE, R. C., M.R.C.S., L.R.C.P. Lond., Senior Obstetric House Physician; HALE, J., B.Ch. Cantab., Junior Obstetric House Physician; CARDELL, J. D. M., M.R.C.S., L.R.C.P. Lond., Senior Ophthalmic House Surgeon; ROBERTS, E. D. T., M.R.C.S., L.R.C.P. Lond., Junior Ophthalmic House Surgeon; CAVENAGH, J. B., M.B., B.Ch. Oxon., BYRNE, C. H. C., M.B., B.S. Lond., HOLMES, H. W. H., M.R.C.S., L.R.C.P. Lond., Clinical Assistants (Throat); BACK, G. A., M.R.C.S., L.R.C.P. Lond., Clinical Assistant (Skin); HOLMES, H. W. H., M.R.C.S., L.R.C.P. Lond., Clinical Assistant (Ear).
- Certifying Surgeons under the Factory and Workshop Acts: JARDINE, W. C., M.B., Ch.B. Edin. (Wombwell); HEMMING, C. P., M.R.C.S. (Bishop's Waltham); KINNEAR, F., M.B., Ch.B. Aberd. (Shefford); DARBY, W. S., M.B., B.C. Camb. (Hartow); COURT, C. C. C., M.B., Ch.B. Birm. (Okehampton).

Vacancies.

- For further information refer to the advertisement columns.
- Barnsley, Beckett Hospital and Dispensary.—Sen. H.S. £250.
- Battersea General Hospital (Incorporated), Battersea Park, S.W.—Third Res. M.O. £200.
- Belfast County Borough.—Bacteriologist and Pathologist. £700.
- Bengal, University of Dacca.—Chair of Physical Education. Rs. 9000 to Rs. 12,000.
- Bethnal Green Infirmary, Cambridge-road, Bethnal Green, E.—Asst. Med. Supt. £400.
- Birmingham Children's Hospital.—Jun. Vis. Anaesth. £50. Res. M.O. £150.
- Birmingham General Hospital.—Res. H.S. £100. Res. M.O. £155. Res. Anaesth. £100.
- Birmingham, Queen's Hospital.—Third P. to Out-patients. £50. Cas. S. £100. Dent. S. £50. Surg. Registrar. £100.

- Birmingham University.—Demonstrator in Pathology. £350.
- Blackburn and East Lancashire Royal Infirmary.—Jun. H.S. £250.
- Brighton, Royal Sussex County Hospital.—Asst. H.S. £150.
- Bristol Eye Hospital.—H.S. £150.
- Bristol General Hospital.—Two H.P.'s, H.S., and Obstet. O. and H.S. £175 each.
- Cancer Hospital, Fulham-road.—Asst. P. and Med. Reg. £250.
- Canterbury, Chatham Mental Hospital.—Asst. M.O. £350.
- Cardiff, Talgarth, Breconshire, South Wales Sanatorium.—Second Asst. Res. M.O. £400.
- Chester County Asylum.—Second Asst. M.O. £425.
- Church Army Lads' Sanatorium, near Farnham, Surrey.—Medical Superintendent.
- Colonial Service.—M.O.'s for West African Medical Staff, Government Service in Malaya, East African Protectorates, West Indies (including British Guiana), Fiji, and the Western Pacific, &c.
- Deplford Metropolitan Borough.—Second Asst. M.O.H. and Welfare Officer. £600.
- Devonport, Royal Albert Hospital.—H.S. £200.
- Dorset County Council.—Asst. County M.O.'s. £500.
- Edinburgh Royal Infirmary.—Asst. Path., Asst. Clin. Path. £500 each. Also Second Asst. Clin. Path. £350.
- Egyptian Government, Ministry of Education.—Prof. of Pharmacology. L.E. 1,200-1,440. Lecturer in Anat. L.E. 720.
- Essex Education Committee.—Sch. Med. Inspec. £500.
- Gloucestershire Royal Infirmary and Eye Institution.—H.P. £175.
- Great Yarmouth General Hospital.—H.S. £250.
- Hove, Carr-Burton Memorial Hospital, Sackville-road.—Res. M.O. £250.
- Huddersfield Royal Infirmary.—Asst. H.S. £150.
- Hull Royal Infirmary.—H.S. £200. Asst. H.S. £150.
- Ingham Infirmary and South Shields and Westoe Dispensary.—Jun. H.S. £175.
- Lancashire County Council, Ryfford Sanatorium and Training Centre.—Med. Supt. £800.
- Leeds University, School of Medicine.—Lect. in Exper. Phys. £500.
- Leicester City Isolation Hospital and Sanatorium, Groby-road.—Two Res. M.O.'s. £500 and £350 respectively.
- Leicestershire and Rutland Mental Hospital, Narborough, near Leicester.—Jun. Asst. M.O. £350.
- Liverpool, Royal Liverpool Children's Hospital.—Two Res. H.P.'s and Two Res. H.S.'s. £90 each.
- Liverpool, Royal Southern Hospital.—Two H.P.'s and Three H.S.'s. £100.
- Liverpool School of Tropical Medicine.—Three Medical Men for Clinical and Research Work in Tropical Medicine.
- London County Council Mental Hospital Service.—Asst. M.O.'s.
- London Lock Hospital, Soho, W.—H.S. £200.
- London Temperance Hospital, Hampstead-road, N.W.—Hon. Radiographer. Cas. O. £200. H.P. £120.
- M.A.B. Tuberculosis Service.—Asst. M.O.'s at Margate, £515; at Brentwood, £579.
- Maidstone, Kent County Mental Hospital.—Jun. Asst. M.O. £300.
- Manchester, Ancoats Hospital.—H.S. £150.
- Manchester Royal Eye Hospital.—Jun. H.S. £120.
- Manchester, St. Mary's Hospitals for Women and Children.—H.S. for Whitworth Park Hospital. £100.
- Margate, Royal Sea Bathing Hospital.—Res. S. £200.
- Metropolitan Borough of Wandsworth.—Asst. Tuberc. O. £818.
- Middleton-in-Wharfedale Sanatorium, near Ilkley.—Asst. M.O. £500.
- Newcastle-upon-Tyne Hospital for Sick Children.—Hon. Asst. P.
- Newcastle-upon-Tyne, University of Durham College of Medicine.—Lecturer on Medical Jurisprudence. Sen. and Jun. Demonstrators of Anatomy. £450 and £350 respectively.
- Nottingham General Hospital.—H.S. and H.P. £200 each.
- Orkney, Parish of Rousay and Egilsay.—Res. M.O. £300.
- Reading, Royal Berkshire Hospital.—Second H.S. £200.
- Scarborough Education Committee.—Sch. Dent. S. £250.
- Sheffield Royal Infirmary.—H.P. £150.
- Southport County Borough.—Asst. M.O.H. and Asst. Sch. M.O. £500.
- Southport General Infirmary.—Sen. H.S. £250.
- Stafford, Staffordshire General Infirmary.—H.S. £250.
- University of London.—Prof. of Med. and Director of Med. Clin. £2000.
- Whalley, near Blackburn, "Calderstones," Certified Institution for the Reception of Mental Defectives.—Sen. Asst. M.O. £665.
- The Chief Inspector of Factories, Home Office, S.W., gives notice of a vacancy for a Certifying Surgeon under the Factory and Workshop Acts at Gatehouse.

Births, Marriages, and Deaths.

BIRTHS.

- CARR.—On July 18th, at Makwar, Blue Nile, Sudan, the wife of B. G. D'Rastricke Carr, M.C., Medical Inspector, of a daughter.
- DICKSON.—On August 14th, at Grindley House, Newcastle, Staffordshire, the wife of Robert H. Dickson, F.R.C.S.—a daughter.
- OSBORN.—On August 14th, at Sheet-street, Windsor, the wife of Dr. A. G. Osborn, of a daughter.
- PRENTISS.—On August 9th, the wife of Dr. H. H. Prentiss, of Cowbeech, Sandhurst, Kent, of a daughter.
- WOOLLEY.—On August 13th, at Brunswick-place, Hove, the wife of Lieut.-Col. J. M. Woolley, I.M.S., of a son.

DEATHS.

- CHRISTIE.—On July 22nd, on s.s. *Moghilev*, William Ledingham Christie, M.D., F.R.C.S.
- HENSLEY.—On August 8th, at The Ark, Farnham, Philip John Hensley, M.A., F.R.C.P., M.D., in his 82nd year.
- JONES.—On August 13th, at Lewisham-road, James Jones, M.D., aged 77 years.
- MEARS.—On August 10th, at 13, Windsor-gardens, North Shields, Frederick Charles Mears, M.B., M.R.C.S., L.S.A.
- N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

A NATIVE MEDICAL SCHOOL IN UGANDA.

By E. N. COOK, M.B., B.Sc. LOND.

A NOVEL and interesting experiment in training natives in medical and surgical work is being made in Uganda. The romance of the undertaking lies in this. Native boys who are the raw material from the best schools of the country are being taken, and are receiving a three years' course of training at the large C.M.S. Hospital at Mengo, the native capital of Uganda, where the medical school began its work three years ago. Twelve lads, of the highest standard of education as yet attained in Uganda, were selected by the Native Government and sent to the hospital to be trained. They are extraordinarily keen and readily absorb any knowledge imparted to them. They live in a hostel attached to the hospital and attend lectures on anatomy, physiology, medicine, surgery, elementary chemistry, pharmacy, and English. In the operating theatre they give anaesthetics and assist in the sponging, &c., at operations; in the wards they act as clerks and dressers to the doctors; in the pathological laboratory they examine blood-films and various kinds of specimens. In the dispensary, with its crowd of native and Indian patients, they themselves examine the cases under the direction of the doctors.

It is curious to watch the black man writing a prescription or making up accurately the mixture that has been ordered. The teachers responsible for the training are the doctors and sisters in the hospital, who, over-worked as they are, make time for this voluntary work for the good of the country. Thus the need has arisen for a young and enthusiastic doctor to devote his time to the work. I have taken a part in the working of this school, and can speak from experience of the fascination of breaking new ground—taking intelligent natives and building a medical education upon their school training.

The study of tropical diseases in Central Africa, with all its opportunities of investigating methods of treatment in connexion with a well-organised hospital, is of never-failing interest. Blackwater fever, malaria, tick fever, sleeping sickness, and the like can be studied there better perhaps than in any other country. Research work is needed in many un-pigeonholed diseases, and a well-established medical training centre at the capital will, it is believed, be of value to the whole country in sending out natives trained up to the standard of clinical assistants who will be able to run native dispensaries throughout the country.

The British Government have this year guaranteed the stipend of a doctor to go out under the C.M.S. as superintendent of the medical training in Uganda. It is a unique opportunity for a man keen on teaching, and offers unlimited opportunities of investigating new or partly-known tropical diseases. There is at the present time an urgent need felt for supplying native dispensaries with natives trained in the country, and along with this an anti-venereal campaign is being planned by the Government. Treatment of venereal diseases is taken as a special part of the curriculum, and the students have great facilities in the practical treatment of venereal diseases in the special wards devoted to them. The present lot of students completed their three-years' course last January, and entered for a final examination for a Government certificate. Four students obtained the certificate, and this marks but the first stage in the progress of medical training in Uganda. There is a vast difference between the native medicine-man with his beads and incantations and these lithe and athletic young Baganda Christians, trained under up-to-date medical methods.

The difficulty of this work in Uganda, as compared with India or China, where the medical training of natives has

been going on for years, is that there they have an already educated manhood upon which to graft the medical knowledge, whereas in Uganda general education is as yet in its earliest stages. It is, moreover, a country with no literature as yet, and eventually it is hoped the training will be given in English, but meantime medical handbooks in the vernacular are urgently required. At the present moment the school is closed owing to depletion of staff and the fact that I am on leave in England.

Geographically, the strategic importance of Uganda is fully recognised, and now that German East Africa has been re-labelled Tanganyika Territory there is an "all-red" strip of British territory from Cairo to the Cape. Uganda lies half-way along this journey and is also the terminus of the railway through East Africa from Mombasa. Uganda is rapidly becoming the hub of the African universe, and from

A laboratory class of native students in Uganda.

it will radiate knowledge, progress, and relief of suffering to the surrounding millions who are placed under British protection.

A HANDY INCOME-TAX GUIDE.

A STIFF paper folder of 10 pages entitled "Income-tax and Super-tax: a Tabular View, 1842-1921," explains the 1920 Budget changes, and shows in a concise and handy form the present position of income-tax and super-tax, along with the several rates, exemptions, deductions, allowances, and so forth, now in force. The publication can be obtained from Messrs. Oliver and Boyd, 33, Paternoster-row, London, E.C., at 1s. (post-free, 1s. 2d.), and is well worth the money to any income-tax payer.

THE LONDON ASSURANCE, 1720-1920.

AN assurance company is naturally proud of a history of 200 years, and the souvenir of the bicentenary of the London Assurance which lies before us, written in Mr. G. S. Street's graceful manner and printed for private circulation, gives an interesting picture of bygone days and also a remarkable record of how a well-managed business concern can fight disaster successfully, and from small beginnings grow into a vast and eminently prosperous undertaking. The London Assurance grew out of a scheme of Marine Insurance started in 1719 by Lord Chetwynd, unkindly known as "Chetwynd's Bubble," and another insurance scheme known as "Overall's." A Royal Charter for Marine Insurance was granted in 1720, and one for Fire and Life in 1721. Chetwynd was the first governor, and Overall was an official of the company. In 1731 he was secretary, and in 1755, about which date he died, it appears that there was a deficiency in the funds of £213 3s. 11d. The company had a hard time in its early youth, for some eight months after the granting of the Charter the South Sea Bubble burst. In the first year of its existence the value of the shares (£25) fluctuated between £160 and practically nothing, but nevertheless they weathered the storm.

Mr. Street has collected from the minute books of the company and from sundry newspaper cuttings preserved by

the secretary a collection of interesting facts and occurrences in the history of the institution. In March, 1806, we find the firemen and porters being supplied with clothing. The jacket of the former cost £4 10s., that of the latter £4 8s., "including waistcoats with sleeves and plush breeches." Such clothing inspired the W.S. of Rejected Addresses.

"Starting from short and broken snooze
Each sought his ponderous hob-nailed shoes,
But first his worsted hosen plied,
Plush breeches next in crimson died
His nether bulk embraced.
Then jacket thick of red or blue
Whose massy shoulder gave to view
The badge of each respective crew
In tin or copper traced."

A picture of such badges is given opposite p. 36 of Mr. Street's book.

We have only space for two more incidents. On Feb. 29th, 1768, the office in Birch Lane was held up, quite in to-day's fashion, by a madman, who hit the one clerk over the head with a pistol and decamped with nearly 250 guineas. In 1786 a lady, by name Elizabeth Wade, was tried for setting fire to her lodgings near Coldbath Fields. Much combustible material was found lying about, and the whole of her property was valued at £20. She had shortly before insured with the company for £1500. The chairman of the quarter sessions, however, proceeded, after dwelling on the enormity of her offence, to sentence her to a fine of 1s. and 12 months' imprisonment. Considering the draconic nature of the criminal code at that date—stealing from a shop to the value of 5s. was a capital offence—Elizabeth was extraordinarily lucky.

EGYPTIAN WATER-SUPPLIES.

SINCE the early part of 1915 the Department of Public Health in Egypt has made special efforts to undertake the regular inspection of all public water-supplies, whether in the hands of the Government, of municipalities, companies, or private individuals. Although no special staff was then available for this purpose, the Director of the Public Health Laboratories was placed in charge, in collaboration with the Chief Engineer of the Municipalities and Local Commissions Section of the Ministry of the Interior. These officers visited and reported on the more important supplies, and regular bacteriological examinations were made of drinking water, aerated waters, and ice in Cairo. It is stated by Mr. C. Todd, Director of the Public Health Laboratories,¹ that although a great deal has been done for the provision of water-supplies for the larger towns, much remains to be done even in Cairo and Alexandria; and that most of the smaller towns are still taking their water generally from very questionable sources. Since the beginning of 1915 regular and systematic examination has been made of the Nile water at Cairo by collecting weekly samples "from near the surface of the river in mid-stream at a point opposite the north end of Roda Island, a bottle being let down to arm's length in the river." During the period of low Nile, from January to June inclusive, the suspended solids are low (below 100 parts per million). During June or July the river begins to rise, and from July to September continues to do so, the water being charged with suspended matter amounting to 1235 parts per million (August, 1915) and even 1547 per million in August, 1917. Questions arose as to the plumbo-solvency of Nile water and the use of bleaching powder for purification purposes; its addition up to an amount corresponding to 5 parts of active chlorine per million does not increase the plumbo-solvency in the case of the Nile water, which is not unduly high and lower than that of some European city supplies. From experiments on bleaching powder dried "by passing a current of dry CO₂-free air over the powder contained in a U-tube, and immersed in an oil bath, the temperature of which was slowly raised to a maximum of just under 100° C.," it was found that this mode of drying removes practically every trace of water, leaving a powder which, *when kept dry*, undergoes practically no decomposition when maintained at as high a temperature as 45° C. for a very long period. The Jewell system of mechanical filtration is in use at Beni Suef, and is giving satisfactory results. There are two "decantation basins" (which would be better called "settling tanks" because "decant" means "to pass off gently by inclining," or tilting up the vessel containing the fluid) where alum is added, and from which the water is run on to gravel and sand filters. Samples are examined by a transparency test, which consists in noting the visibility of a platinum wire through a column of the filtered water, 1·20 metres long. This system of filtration is also in use satisfactorily at Giza, Mansura, and elsewhere. At Port Said, Suez, and Ismailia the Puech-Chabal system of sedimentation and filtration also works well. The bacterial content is reduced from 610 per c.c.m. in

the raw water at Port Said to 13 per c.c.m. after decantation and filtration. During the war the laboratories were constantly referred to by the military authorities in regard to water-supplies for the troops in Egypt and the Sinai Peninsula. Several hundreds of these analyses and descriptions of the sources of water are collected in the present report, and form an invaluable record for future reference.

Medical Diary.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

LONDON HOSPITAL MEDICAL COLLEGE.

MEDICAL UNIT, in the Clinical Theatre of the London Hospital, E.

MONDAY, August 23rd.—2 P.M., Mr. Goulden: Eye Conditions in Focal Brain Disease.

WEST LONDON POST-GRADUATE COLLEGE, West London Hospital, Hammersmith, W.

MONDAY, August 23rd.—12.15 P.M., Dr. Burnford: Pathological Demonstration. 5 P.M., Mr. MacDonald: Stricture.

TUESDAY.—10.30 A.M., Surgical Registrar: Demonstration of Cases. (Surgical Wards.) 4.30 P.M., Mr. Addison: Practical Surgery.

WEDNESDAY.—10.30 A.M., Mr. MacDonald: Demonstration of Cystoscopy. 4.30 P.M., Dr. Owen: Demonstration of Medical Cases. (Lecture Room.)

THURSDAY.—12 noon, Mr. Sinclair: Abdominal Diagnosis. 4.30 P.M., Mr. B. Harman: Disorders of the Lacrymal Sac.

FRIDAY.—12.15 P.M., Dr. Burnford: Applied Pathology. 4.30 P.M., Mr. D. Buxton: Local Analgesia in Dental Cases.

SATURDAY.—12 noon, Mr. Sinclair: Surgical Diseases of the Abdomen.

Daily.—10 A.M., Ward Visits. 2 P.M., In-patient, Out-patient Clinics and Operations.

MALE LOCK HOSPITAL, Dean-street, W.

MONDAY, August 23rd, WEDNESDAY, AND FRIDAY.—5 P.M., Dr. C. Russ: Demonstration of the Treatment of Gonorrhœa by Electrolysis.

Subscriptions may commence at any time, and are payable in advance. Cheques and P.O.'s (crossed "London County Westminster and Parr's Bank, Covent Garden Branch") should be made payable to Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C. 2

¹ Report on Egyptian Water-Supplies, Cairo, Government Press, 1920.

STUDENTS' GUIDE—SESSION 1920-1921.

THE scheme upon which the Students' Number of THE LANCET is constructed will make it easy, we hope, for all who consult it to find what they seek. The General Council of Medical Education and Registration is the controlling authority of all the medical education of the country, and its responsibility for the efficiency of the Medical Register and for the maintenance of the examination standard is first explained. The student must be taught as well as examined, and as the systems under which he or she can obtain instruction do not conform to one pattern, the various curricula are described in detail, and under their respective headings the necessary information will be found concerning the facilities for medical study offered at the different teaching centres of the United Kingdom. The regulations for the examinations, both preliminary and professional, at these centres are set out so that the student desiring to obtain a medical degree from any university, or a diploma from any medical corporation, may ascertain the course of clinical instruction and the conditions under which submission for examination has to take place. The metropolitan medical schools and hospitals are grouped under the University of London, of which they are constituent bodies, although their educational opportunities are offered to other universities as well as to the medical corporations. A similar plan is adopted in dealing with the provincial universities, the hospitals in direct connexion with which are described with the universities; for though the hospitals may not be official schools of the universities they supply an integral section of the teaching required by the graduates. Upon obtaining degrees or diplomas admission to the Register follows, and greater education begins. The prudent young doctor already knows what he or she desires to make the next step, and there is a large range of choice displayed. The inducements to enter one of the Services should prevail more than they have done of recent years. An account is given of the conditions under which commissions can be obtained in the Navy, Army, Indian, and Air Force Medical Services, and in the Colonial Medical Service.

GENERAL COUNCIL OF MEDICAL EDUCATION AND REGISTRATION OF THE UNITED KINGDOM.

POWERS, DUTIES, AND CONSTITUTION OF THE GENERAL MEDICAL COUNCIL.

THE powers and duties of the General Medical Council, or "General Council of Medical Education and Registration of the United Kingdom" to give the Council its full title, have been set out in detail in many previous Students' Numbers of THE LANCET. It is first a registering body: no person, even though his qualifications have been obtained, is a legally qualified medical practitioner unless his name appears on the Medical Register. Secondly, it is a standardising body, ensuring that the education of medical men is kept up to an efficient standard by scientific examination. Thirdly, it is a penal and disciplinary body, having power to remove from the Register any practitioner adjudged guilty of conduct "infamous in a professional respect." Fourthly, to the Council is committed the codification of pharmaceutical remedies. The duties of the Council are thus primarily of a public nature, and its construction shows its fitness for its fourfold responsibilities.

The Council at present consists of 38 members, of whom, as will be seen by the annexed list, all but 11 are official representatives of some corporate body. Five members are chosen by the Crown on the advice of the Privy Council, and six others are elected by the members of the medical profession as Direct Representatives.

President of the General Council: Sir Donald MacAlister. Members of the General Council: Sir Norman Moore, chosen by the Royal College of Physicians of London; Mr. Holburt Jacob Waring, F.R.C.S., Royal College of Surgeons of England; Dr. Benjamin Bloomfield Connolly, Apothecaries' Society of London; Mr. Arthur Thomson, F.R.C.S., University of Oxford; Mr. Frederick Gowland Hopkins, M.A., M.B., University of Cambridge; Dr. Robert Howden, University of Durham; Dr. Sydney Russell Wells, University of London; Dr. Henry Roy Dean, Victoria University of Manchester; Sir Harry Gilbert Barling, University of Birmingham; Dr. Richard Caton, University of Liverpool; Dr. Thomas Wardrop Griffith, University of Leeds; Dr. John Beresford Leathes, University of Sheffield; Sir Isambard Owen, University of Bristol; and Dr. David Hepburn, University of Wales. Dr. William Russell, chosen by the Royal College of Physicians of Edinburgh; Sir James William Beaman Hodsdon, Royal College of Surgeons of Edinburgh; Dr. James Alexander Adams, Royal Faculty of Physicians and Surgeons of Glasgow; Dr. H. Harvey Littlejohn, University of Edinburgh; Sir Donald MacAlister, University of Glasgow; Dr. Matthew Hay, University of Aberdeen; and Dr. John Yule Mackay, University of St. Andrews. Sir John William Moore, chosen by the Royal College of Physicians of Ireland;

Sir Arthur Gerald Chance, Royal College of Surgeons in Ireland; Dr. Edward Magennis, Apothecaries' Hall of Ireland; Dr. Andrew Francis Dixon, University of Dublin; Denis Joseph Coffey, M.B., National University of Ireland; and Mr. Thomas Sinclair, F.R.C.S., Queen's University of Belfast. Nominated by His Majesty, with the advice of his Privy Council: Sir Francis Henry Champneys, Sir George Newman, Mr. Norman G. Bennett, Dr. John Christie McVail, and Dr. Edward Coey Bigger. Elected as Direct Representatives: Dr. J. A. MacDonald, Sir Thomas Jenner Verrall, Dr. Robert A. Bolam, Mr. E. B. Turner, Dr. Norman Walker, and Dr. Leonard Kidd. Treasurers of the General Council: Sir Norman Moore and Mr. Holburt J. Waring.

THE EDUCATIONAL CURRICULUM.

Professional Education.—The course of professional study after registration occupies at least five years. The Final Examination in Medicine, Surgery, and Midwifery must not be passed before the close of the fifth academic year of medical study.

Registration and Preliminary Examination of Medical Students.—The following are the General Medical Council's Regulations in reference to the registration of students in medicine:—Every medical student should be registered in the manner prescribed by the Council. The registration of medical students is placed under the charge of the Branch Registrars. Every person desirous of being registered as a medical student should apply to the Branch Registrar of the division of the United Kingdom in which he is residing; and should produce or forward to the Branch Registrar a certificate of his having passed a preliminary examination as required by the General Medical Council, and evidence that he has attained the age of 16 years, and has commenced medical study at an institution approved by the Council. The Branch Registrar shall enter the applicant's name and other particulars in the Students' Register and shall give him a certificate of such registration. Each of the Branch Registrars shall supply to the several licensing bodies, medical schools, and hospitals, in that part of the United Kingdom of which he is registrar, a sufficient number of blank forms of application for the registration of medical students. The commencement of the course of professional study recognised by any of the qualifying bodies should not be reckoned as dating earlier than 15 days before the date of registration. In addition to the universities and schools of medicine there are many institutions where medical study may be commenced. Applications for special exceptions are dealt with by the Students' Registration Committee, which reports all such cases to the Council.

Regulations for Maintenance of Register of Medical Students.

The following examinations have been approved by the Council:—(a) The final examinations for the degrees in Arts and Science of any University of the United Kingdom or of the British Dominions. (b) All examinations which are accepted for Matriculation in the Faculties of Arts or

Pure Science in any one of the Universities of Great Britain or in the Queen's University of Belfast. (c) All examinations not included under the foregoing section (b), which are accepted for Matriculation in the Faculty of Medicine in any one of the Universities of the United Kingdom of Great Britain and Ireland provided the examination is completed at not more than two periods of examination, and that the pass-certificate (or certificates) includes English, Mathematics, Latin (or Greek or Hebrew), and at least one other subject named in the following list:—Latin, Greek, Hebrew, Arabic, Persian, French, German, Spanish, Italian, Russian, or any approved modern language. (d) The Council may grant special recognition to the following examinations not included under the foregoing sections (a), (b), and (c):—(1) The final examinations for the degrees in Arts and Science of any specially recognised Foreign University. (2) Examinations conducted by approved Examining Bodies within the United Kingdom under the provisions set forth in the foregoing section (c). (3) Examinations conducted by approved Examining Bodies out of the United Kingdom under the provisions set forth in the foregoing section (c), and under such other conditions as the Council may impose in each case.

List of Bodies whose Examinations are accepted under the foregoing Regulations.

I. Examinations in Great Britain.

(1) The Matriculation Examinations in the Faculties of Arts and Science of, and all examinations accepted in lieu thereof by, the following Universities: Oxford (including Responsions and Moderations), Cambridge (including the Previous Examination and the General Examination), Durham, London, Manchester, Birmingham, Liverpool, Leeds, Sheffield, Bristol, Wales, Edinburgh, Glasgow, Aberdeen, St. Andrews. These examinations are accepted subject to the conditions set forth under Section 2 (b) above. (2) The Preliminary Examinations in the Faculty of Medicine of, and all examinations accepted in lieu thereof by, the Universities of Durham, Edinburgh, Glasgow, Aberdeen, St. Andrews. These examinations are accepted subject to the conditions of Section 2 (c) above. (3) Specially recognised Examinations conducted by approved bodies.

The following Schools Examinations have been recognised by the English Board of Education and are accepted by the General Medical Council under the conditions noted below.

AS FIRST EXAMINATIONS.

1. School Certificate Examination of the Oxford and Cambridge Schools Examination Board.
2. Senior Local Examination of the Oxford Delegacy for Local Examinations.
3. Senior Local Examination of the Cambridge Local Examinations and Lectures Syndicate.
4. School Certificate Examination of the University of Bristol.
5. First School Certificate Examination of the University of Durham.
6. General School Examination of the University of London.
7. School Certificate Examination of the Northern Universities Joint Matriculation Board.

AS SECOND EXAMINATIONS.

8. Higher Certificate Examination of the Oxford and Cambridge Schools Examination Board.
9. Higher School Certificate Examination of the Oxford Delegacy for Local Examinations.
10. Higher School Certificate Examination of the Cambridge Local Examinations and Lectures Syndicate.
- (a) 11. Higher School Certificate Examination of the University of Bristol.
12. Higher Certificate Examination of the University of Durham.
- (a) 13. Higher School Certificate Examination of the University of London.
14. Higher Certificate Examination of the Northern Universities Joint Matriculation Board.

(A) The First Schools Examination Certificate is accepted, provided it shows either (a) that English and mathematics have been passed "with credit," or (b) that English and a language other than English have been passed "with credit"; and also that mathematics has been passed on a "sufficient" standard. (The certificate under (b) must show by explicit attestation of the examining authority that mathematics has been passed on a "sufficient" standard.)

(B) A First Schools Examination Certificate which does not fulfil one or more of the foregoing conditions is accepted, provided it is supplemented either (i.) by further Schools Examination Certificates obtained subsequently which fulfil (a) or (b); or (ii.) by certificates obtained in the Second (Higher) Schools Examination which show that the deficient subjects (English, another language, mathematics, as the case may be) have been passed (whether as "full" or as "subsidiary" subjects) at the Second Schools Examination.

Other certificates accepted under Clause 2 (b). Scottish Education Department: Leaving Certificates.

Other certificates accepted under Clause 2 (c). Scottish Education Department: Intermediate Certificate. Central Welsh Board: Senior Certificate. University of St. Andrews: Final Examination for Diploma of L.L.A. College of Preceptors: Senior Certificate; Preliminary Examination for Medical Students Certificate. Educational Institute of Scotland: Preliminary Medical Examination Certificate.

II. Irish Examinations.

University of Dublin: Matriculation Examination (a) Junior Freshman Term Examination (exclusive of Trigonometry); (b) Special Preliminary Examination to be held in March, the standard and subjects of which shall be those of a Junior Freshman Examination (exclusive of Trigonometry); (c) Junior Exhibition Examination on obtaining marks of sufficient merit in the subjects of (a) or (b); (d) Examinations for the First, Second, Third, or Fourth Year in Arts. (Certificate to be signed in the approved form by the Medical Registrar of the University.) Queen's University of Belfast: Matriculation Examination. National University of Ireland: Matriculation Examination. Intermediate Education Board of Ireland: Middle Grade Examination, with Honours in three subjects; Senior Grade Examination. Royal Colleges of Physicians and Surgeons in Ireland: Preliminary Examination. These Examinations are accepted subject to the conditions set forth in Section 2 (c) above.

The remainder of the curriculum, though all under the supervision of the Council, is in detail in the hands of the various degree- and diploma-granting bodies whose representatives are members of the General Medical Council. In the next pages we give the regulations of the various examining bodies, but it must always be remembered that the examinations are under the supervision of the General Medical Council, who visit the various centres in turn and closely inspect the procedure.

III. Examinations Held Out of the United Kingdom.

Every Certificate from Indian, Colonial, and Foreign Universities and Colleges must contain evidence that the Examination has been conducted by or under the authority of the Body granting it, must include all the subjects required by the General Medical Council, and must state that all the subjects of Examination have been passed in at not more than two examinations; copies of the form of the required Certificate are supplied by the Registrar of the Council for the purpose. In the case of Natives of India or other Oriental countries whose vernacular is other than English an Examination in a Classical Oriental Language (e.g., Sanskrit, Arabic, Chinese) may be accepted instead of an Examination in Latin. The Abiturienten-Examen of the Gymnasien and Real Schulen on the continent and the examinations entitling to the French diplomas of Bachelier ès Lettres and Bachelier ès Sciences and other corresponding Entrance Examinations to the Universities in Europe are recognised by the General Medical Council.

These examinations are accepted subject to the conditions set forth in Section 2 (c) above.

Further particulars are given in the Students' Regulations, which can be obtained at the offices of the Council, price 1s. 2d.

Registration of Medical Practitioners.

Under the provisions of the Medical Act, 1858, any person possessing one or other of the medical qualifications enumerated in the schedule to the Act is entitled to registration by the General Medical Council on producing to the registrar of a Branch Council proper evidence of qualification. Registration entitles him, in the words of the Act of 1886:—

"..... To practise medicine, surgery, and midwifery in the United Kingdom, and (subject to any local law) in any other part of [Her] Majesty's dominions, and to recover in due course of law in respect of such practice any expenses, charges in respect of medicaments or other appliances, or any fees to which he may be entitled"

These qualifications are enumerated in the Medical Register, printed each year under the direction of the Council, and the course of study necessary to obtain each of them is duly set out in the succeeding pages.

A number of diplomas granted in British possessions and in certain foreign countries entitle the holder to registration in the colonial or foreign list respectively of the Medical Register, and therefore to practise medicine within the borders of the United Kingdom. Some account of these diplomas will be given in a later issue. It should, however, be carefully noted that, where any local registration is required for legal qualification, it is essential that, before registration in the United Kingdom, evidence should be produced of registration in the country, province, or state in which the qualification was obtained.

Officers of the Council.

Norman C. King, Registrar of the General Council and of the Branch Council for England, 44, Hallam-street, Portland-place, W. 1.—T. H. Graham, O.B.E., Registrar of the Branch Council for Scotland, 20, Queen-street, Edinburgh.—Richard J. E. Roe, Registrar of the Branch Council for Ireland, 35, Dawson-street, Dublin. All communications should be addressed to "The Registrar" and not by name.

THE MEDICAL EXAMINING BODIES

AND

SCHOOLS OF THE UNITED KINGDOM.

A GUIDE TO THE FACILITIES FOR OBTAINING THE VARIOUS
MEDICAL DEGREES AND OTHER QUALIFICATIONS
FOR THE BRITISH MEDICAL REGISTER.

I.—ENGLAND AND WALES.

THE UNIVERSITIES.

UNIVERSITY OF OXFORD.

THERE are two degrees in Medicine, *B.M. and D.M.*, two degrees in Surgery, *B.Ch. and M.Ch.*, and two diplomas, *Public Health and Ophthalmology*.

Graduates in Arts (*B.A. or M.A.*) are alone eligible for the degrees. The most convenient course for the *B.A.* degree for intending graduates in Medicine is to take Responsions, the Preliminary Science Examinations mentioned below, and the Final Honour School of Physiology. In order to obtain the degrees of *B.M.* and *B.Ch.* the following examinations must be passed:—1. Preliminary subjects: Mechanics and Physics, Chemistry, Zoology, and Botany. 2. Professional. (a) First Examination: Subjects—Organic Chemistry, unless the candidate has satisfied the Examiners in Part I. Chemistry in the Natural Science School; Human Physiology, unless he has obtained a first or second class in Animal Physiology in the Natural Science School; Human Anatomy. (b) Second Examination: Subjects—Medicine, Surgery, Midwifery, Pathology, Forensic Medicine with Hygiene, Materia Medica and Pharmacology. The approximate dates of the examinations are as follows:—Preliminaries—Zoology, Botany, and Chemistry, December and June; Mechanics and Physics, March and June; Professional (First and Second *B.M.*), June and December.

The First Examination for the degrees of *B.M.* and *B.Ch.* may be passed as soon as the Preliminary Scientific Examinations have been completed. Anatomy and Physiology are to be passed together, and Organic Chemistry may be taken before or after these have been passed.

The Second Examination may be passed after the completion of the first, but Pathology, Hygiene, and Materia Medica and Pharmacology may be taken before or with the remaining subjects. Before admission to the Second Examination candidates must present certificates of attendance on a course of laboratory instruction in Practical Pathology and Bacteriology and of having acted as post-mortem clerk for three months, surgical dresser for six months, and clinical clerk for six months. Also they must produce certificates of instruction in Infectious and Mental Diseases, and of attendance on Labours, of proficiency in the practice of Vaccination and Anæsthetics, and of having attended a course of Practical Pharmacology. Also in respect of the First Examination candidates must present certificates showing that they have dissected the whole body once and have attended courses of laboratory instruction in Practical Histology and Practical Physiology.

The degree of *D.M.* is granted to Bachelors of Medicine of the University provided they have entered their thirtieth term and have composed on some medical subject a dissertation which is approved by the professors in the Faculty of Medicine and examiners for the degree of *B.M.* whose subject is dealt with. The degree of *M.Ch.* is granted to Bachelors of Surgery of the University who have entered their twenty-first term, who are members of the surgical staff of a recognised hospital, or have acted as Dresser or House Surgeon in such a hospital for six months, and who have passed the *M.Ch.* examination in Surgery, Surgical Anatomy, and Surgical Operations. This examination is held annually, in June, at the end of the Second *B.M.* Examination.

Diploma in Ophthalmology, the examination is held in July; Diploma in Public Health, in June and November.¹ Travelling Fellowship, Scholarships, and Prizes.—A Radcliffe Travelling Fellowship is awarded annually after an examination held in February. It is tenable for three years and is of the annual value of £200. The examination is in Physiology, Pathology, and Hygiene,

and is partly "practical." Candidates must be graduates in Medicine of the University. The holder must travel abroad for the purpose of medical study. Application should be made to the Radcliffe Examiners, Radcliffe Library, University Museum. A Rolleston Memorial Prize is awarded once in two years to members of the Universities of Oxford and Cambridge of not more than ten years' standing for an original research in some Biological subject, including Physiology or Pathology. The Radcliffe Prize, founded by University College (1907), is of the value of £50 and is awarded biennially for research in some branch of medical science. The Theodore Williams Scholarships of the value of £50 each are awarded annually in the subjects of Anatomy, Physiology, and Pathology. A King's College Hospital Burney Yeo Scholarship of £80 is awarded each year. The Scholarships in Science which are offered by several Colleges are open to those who intend to pursue Medicine. The value of these scholarships is usually £80 a year for four years.

In addition to the University lectures and classes the several Colleges provide their undergraduates with tuition for all examinations up to the *B.A.* degree.

In the Radcliffe Infirmary and County Hospital clinical instruction is given by the Regius Professor of Medicine, the Litchfield Lecturers in Medicine and Surgery, and the other physicians and surgeons. Instruction is also given in post-mortem work and Clinical Pathology in connexion with the courses in Pathology. Post-graduate courses will be held at the beginning of October.

More detailed information may be obtained from the University Calendar; from the Examination Statutes, 1918 (both of which are published by the Clarendon Press); from the Regius Professor of Medicine; and from the Professors in the several departments of medical science.

UNIVERSITY OF OXFORD: RADCLIFFE INFIRMARY AND COUNTY HOSPITAL.—Courses of instruction are given in connexion with the Oxford University Medical School. These include (1) a course in Practical Medicine by the Regius Professor of Medicine; (2) Clinical lectures by the Litchfield Lecturers in Medicine and Surgery; and (3) tutorial instruction and demonstrations in special Regional Anatomy (medical and surgical), methods of Medical and Surgical Diagnosis, and Surgical Manipulation. (4) Pathological demonstrations and instruction in post-mortem work are given by the Assistant Pathologist. Practical Pharmacy is taught in the Radcliffe Dispensary. Opportunities are offered to students who wish to act as surgical dressers and clerks. The Hospital contains 210 beds.

UNIVERSITY OF CAMBRIDGE.

The student must enter at one of the Colleges, or as a non-collegiate student, and keep nine terms (three years) by residence in the University. He must pass the Previous Examination in Classics, Mathematics, &c., if possible, before he comes into residence in October, or he may obtain exemption through the Oxford and Cambridge Schools Examination Board, the Oxford or Cambridge Senior Local Examinations, the London Matriculation Examination, the Scotch Education Department, Responsions at Oxford, and the Joint Matriculation Board of the Universities of Manchester, Liverpool, Leeds, and Sheffield, the Matriculation Examination of the University of Birmingham, or by being graduates of certain other Universities in the United Kingdom. He may then devote himself to medical study in the University, &c. Or he may, as nearly all students now do, proceed to take a degree in Arts by passing either (a) the General Examination and one Special Examination, or (b) two Special Examinations for the ordinary *B.A.* degree, or an Honours degree in one of the Triposes. The Natural Sciences Tripos is taken most frequently, as some of the subjects are practically the same as those for the first and second *M.B.*

For the degree of Bachelor of Medicine (*M.B.*) five years of medical study are required either in Cambridge or at one of the recognised Schools of Medicine. The first three or four years are usually spent in Cambridge till he has passed, say, the examination for Part I. of the Natural Sciences Tripos and the first and second examinations for *M.B.* Hospital practice and many of the requisite lectures may be attended in Cambridge, and some students remain to attend lectures and hospital practice until they

¹ The regulations for the Diplomas in Public Health and Sanitary Science of the various Examining Bodies will be found on p. 473.

have passed the second part of the second examination for M.B. The laboratories for Botany, Chemistry, Physics, Biology, Zoology, Human Anatomy, Physiology, Biochemistry, Pathology, Bacteriology, Pharmacology, Psychology, and Public Health are well equipped. Addenbrooke's Hospital, the Infectious Diseases Hospital, the Cambridge Research Hospital, and the Field Laboratories are utilised for study and research.

There are three examinations for M.B. The *first* includes (1) Chemistry, (2) Physics, and (3) Elementary Biology. These parts may be taken together or separately. The *second* is divided into two parts—viz., (1) Human Anatomy and Physiology; and (2) Pharmacology and General Pathology. The *third* is also divided into two parts: (1) Principles and Practice of Surgery (including Special Pathology and Midwifery and Diseases Peculiar to Women); and (2) Principles and Practice of Physic (including Diseases of Children, Mental Diseases, Medical Jurisprudence), Pathology (including Hygiene and Preventive Medicine), and Pharmacology (including Therapeutics and Toxicology). The examinations are partly in writing, partly oral, and partly practical, in the hospital, in the dissecting room, and in the laboratories. An Act has then to be kept in the Public Schools, by the candidate reading an original dissertation composed by himself and being examined orally on some subject approved by the Regius Professor of Physic.

Candidates who have passed both parts of the third M.B. examination are admitted to the registrable degree of *Bachelor of Surgery (B.Ch.)* without separate examination and without keeping an Act.

The degree of *Doctor of Medicine (M.D.)* may be taken three years after that of M.B. or four years after that of M.A. The candidate is required to produce certificates of having been engaged in Medical Study for five years, and if an M.A., to pass the same examinations as are required for the degree of M.B. An Act has to be kept, consisting of an original Thesis sustained in the Public Schools with *viva voce* examination; and a short extempore essay has to be written on a topic taken from the general subject of his thesis, whether it be Physiology, Pathology, Pharmacology, the Practice of Medicine, State Medicine, or the History of Medicine.

For the degree of *Master of Surgery (M.Ch.)* the candidate must have passed all the examinations for B.Ch., or, if he is an M.A., have obtained some other registrable qualification in surgery. He is required either (1) to pass an examination in Principles and Practice of Surgery, Surgical Anatomy and Surgical Operations, and Pathology, and to write an extempore essay on a Surgical Subject; or (2) to submit to the Medical Board original contributions to the advancement of the Science or Art of Surgery. Before he can be admitted to the examination two years at least must have elapsed from the time when he completed all required for the degree of B.Ch. Before submitting original contributions he must have been qualified at least three years.

Diplomas are granted in Medical Radiology and Electrology, and in Psychological Medicine. Candidates must hold a recognised medical qualification.

Women Students.—Increased facilities have been offered to students of Girton and Newnham Colleges, and they are admitted to the First and Second M.B. Examinations under certain conditions.

University Prize in Medicine.—The one University Prize in Medicine, the Raymond Horton Smith Prize (value £19), is awarded to that candidate for the degree of M.D. who presents the best thesis for the degree during the academical year, provided that he has taken honours in a tripos examination. Medical Studies are endowed by the numerous Natural Science scholarships at the various colleges, information about which can be obtained from the respective Tutors.

An abstract of the Regulations and Schedules of the range of the examinations in Chemistry, Physics, Biology, Pharmacology, and General Pathology may be obtained upon sending a stamped directed envelope to the Registry, the Registry, Cambridge.

ADDENBROOKE'S HOSPITAL.—Clinical Lectures in Medicine and Surgery, in connexion with Cambridge University Medical School, are given at this hospital twice a week during the academical year; and practical instruction in Medicine and Surgery is given in the wards and out-patients'

rooms by the physicians and surgeons daily during the term time and vacations. The fee for pupilship is 3 guineas a term. All communications by students should be made to Dr. Aldren Wright.

UNIVERSITY OF LONDON.

The University of London was established by Royal Charter in 1836 as an examining and degree conferring body with affiliated colleges but no direct teaching functions. In 1900 it was reconstituted under the Act of Parliament 1898 and became a teaching as well as an examining body. Many schools already existing became constituent colleges, including all the metropolitan medical schools. Lecturers were also appointed in special subjects.

Teaching Staff.—The teaching staff of the University is organised under two heads: 1. Appointed teachers—i.e., such as are appointed by, and are paid out of the funds of, the University. 2. Recognised teachers—i.e., those who have been appointed and are paid by the several schools of the University and other institutions at which instruction is given under the auspices of the University, and who have been recognised by the Senate as conducting work of University standard. Courses by non-recognised teachers may also be approved in schools of the University. The lecturers in the Medical Sciences and the professors in the Faculties of Medicine in University College, London, and King's College, London, will be found enumerated under their respective schools.

Internal and External Students.—All the examinations of this University are open to men and women alike. Matriculated students of the University may be either internal or external. Internal students of the University are students who have matriculated at the University and who are pursuing a course of study approved by the University, either (a) under the direct control of the University or a committee appointed thereby; or (b) under one or more of the appointed or recognised teachers of the University. Centres for preliminary and intermediate medical studies have been established by the University at University and King's Colleges. Internal students must pursue their studies at one of the above centres, or at one of the medical schools connected with the University. These are St. Bartholomew's Hospital, Charing Cross Hospital, St. George's Hospital, Guy's Hospital, King's College Hospital, the London Hospital, St. Mary's Hospital, the Middlesex Hospital, St. Thomas's Hospital, University College Hospital, Westminster Hospital, and the London (Royal Free Hospital) School of Medicine for Women. The London School of Tropical Medicine and the Lister Institute of Preventive Medicine are also recognised as schools of the University in special departments. External students are all other matriculated students, and may pursue their studies at other universities and medical schools, presenting themselves for examination at the University.

Faculty of Medicine.—The Faculty of Medicine grants the joint degrees of M.B., B.S. (*Bachelor of Medicine and Surgery*), and the higher separate degrees of M.D. (*Doctor of Medicine*) and M.S. (*Master of Surgery*).

The curriculum for the Bachelor's degrees is now five and a half years from the time of matriculation, with certain exceptions which must be looked for in the official regulations of the University, to be obtained from the Principal Officer, University of London, South Kensington, S.W. 7, and the examinations formerly known as the Preliminary Scientific, the Intermediate, and the Final Examination in Medicine are now respectively entitled the First, Second, and Third Examinations for Medical Degrees. Part II. of the former Preliminary Scientific Examination has now been made Part I. of the Second Examination.

A. Internal Students.—In order to be admitted to the Bachelor's degrees a student must normally, after registration as an internal student, have: (1) Attended prescribed courses of study for five and a half years in one or more schools of the University. (2) Passed the following examinations, under the conditions mentioned below: (a) The First Examination for Medical Degrees in Inorganic Chemistry, Physics, and General Biology; (b) the Second Examination for Medical Degrees: Part I., Organic and Applied Chemistry; Part II., Anatomy, Physiology, and Pharmacology, including Pharmacy and Materia Medica; (c) the Third Examination for Medical Degrees, or M.B., B.S. Examination; Medicine and Surgery, Midwifery and Diseases of Women, Pathology, Forensic Medicine and Hygiene.

B. External Students.—To be admitted to the Bachelor's degrees an external student must (1) have passed the Matriculation examination or have been exempted therefrom under Statute 116 not less than five and a half years previously; (2) have passed subsequent examinations similar to those required of an internal student; and (3) have been engaged in professional studies during the five and a half years subsequently to Matriculation and four and a half years subsequently to passing the First Examination for Medical Degrees at one or more of the medical institutions or schools recognised by this University for the purpose, one year at least of the four and a half years to have been spent in one or more recognised institutions or schools.

The First Examination for Medical Degrees (Inorganic Chemistry, Physics, and General Biology) will take place twice in each year, commencing on the Monday following Dec. 7th and on the second Monday in July. It must be passed not less than nine months after matriculation.

The Second Examination for Medical Degrees (Part I.): Organic and Applied Chemistry.—This examination will take place twice in each year, commencing on the Wednesday following the third Monday in March and on the afternoon of the Thursday following the second Monday in July. No candidate will be admitted to this examination within six months of having passed the First Examination.

The Second Examination for Medical Degrees (Part II.) takes place twice in every year, commencing on the Tuesday following the third Monday in March and on the Tuesday following the first Monday in July. The subjects of the examination are Anatomy, Physiology, and Pharmacology, including Pharmacy and Materia Medica. No candidate shall be admitted to the examination unless he has passed the First Examination for Medical Degrees at least 18 months previously, and has passed Part I. of the Second Examination for Medical Degrees.

The Third or M.B., B.S. Examination.—The M.B., B.S. examination takes place twice in each year, commencing on the fourth Monday in October and on the first Monday in May. No candidate will be admitted to this examination unless he has completed the Second Examination for Medical Degrees, together with a course of study summarised below, nor within three years from the date of passing the Second Examination, Part. II. (1) Principles and Practice of Medicine; (2) Clinical Methods and Physical Diagnosis; (3) Insanity (with clinical demonstrations at a recognised Asylum); (4) Therapeutics; (5) Vaccination; (6) Principles and Practice of Surgery; (7) Operative Surgery, Surgical Anatomy, Practical Surgery, and the Administration of Anæsthetics; (8) Diseases of the Eye, Ear, Throat, and Skin; (9) Lectures and Demonstrations on Midwifery and Diseases of Women; (10) Practical Midwifery, the conduct of at least 20 Labours, and practice as a Clinical clerk in Gynaecological work; (11) Pathology and Bacteriology; (12) work of the Post-mortem room; (13) Forensic Medicine; and (14) Hygiene. He must also have attended the Medical and Surgical practice of a recognised hospital for two years and a course of instruction at a recognised Fever Hospital for two months. He must have had clinical instruction and must have held the posts of medical clinical clerk and surgical dresser for periods of six months each. Candidates will be examined in Medicine (including Therapeutics and Mental Diseases), Pathology, Forensic Medicine and Hygiene, Surgery, Midwifery, and Diseases of Women. The subjects may be divided into two groups—namely: (1) Medicine, Pathology, Forensic Medicine, and Hygiene; and (2) Surgery, Midwifery, and Diseases of Women. These groups may be taken either separately or together. The list of candidates who have passed will be published in two parts—namely, an Honours list and a Pass list. Bachelors of Medicine of this University who graduated in or before May, 1904, may obtain the B.S. degree by passing the Surgical part of the M.B., B.S. examination.

Doctor of Medicine.—The examination for this degree takes place twice in each year, commencing on the first Monday in December and on the first Monday in July. Candidates may present themselves for examination in one of the following branches, namely: (1) Medicine; (2) Pathology; (3) Mental Diseases; (4) Midwifery and Diseases of Women; (5) State Medicine; and (6) Tropical Medicine. Any candidate for the degree of M.D. may transmit to the Registrar a thesis or published work having definite relation to the branch of Medicine in which he is a candidate, and

if the thesis be approved by the examiners the candidate may be exempted from a part or from the whole of the written examination in that subject.

Master in Surgery.—The examination for the degree of Master in Surgery takes place twice in each year and commences on the first Monday in December and on the first Monday in July.

Fees.—Matriculation £2 2s. for each entry. At provincial examinations an additional local fee is charged. First examination for Medical Degrees: £6 6s. for each entry to the entire examination. For re-examination in one subject the fee is £2 2s. In the second examination, Part I. £2 2s., repeated on each subsequent entry; Part II. £3 8s. for the whole examination. Third examination: £10 10s. for each entry to the whole examination. M.D. Examination: £21; for re-examination £10 10s. M.S. Examination: As for M.D.

Full details of the prescribed curricula of study and the names of the recognised Internal and External Schools of the University, can be obtained free on application to the Principal Officer, University of London, South Kensington, S.W.

MEDICAL SCHOOLS OF THE UNIVERSITY OF LONDON.¹

ST. BARTHOLOMEW'S HOSPITAL AND COLLEGE.—The hospital contains 757 beds, of which 687 are for patients in the hospital at Smithfield and 70 for convalescent patients at Swanley. It receives over 8000 in-patients annually and its out-patients and casualties amount to more than 75,000 annually. Special departments have been organised for Diseases of Women and Children, the Eye, Ear, Larynx, and Skin, as well as for Orthopædic and Dental Surgery, and for Electro-therapeutics and X Ray work. Surgical operations take place every day at 1.30 P.M. and Surgical Consultations are held on Thursdays at the same hour. Medical Consultations are held on Thursdays at 3.15 P.M. The physicians and surgeons deliver clinical lectures weekly during both the winter and the summer sessions. Clinical Lectures on all special subjects are also given. The visits of the physicians and surgeons are made at 1.30.

Ten house physicians and ten house surgeons are appointed annually, and are provided with rooms and board by the hospital authorities and receive £80 a year as salary. A resident midwifery assistant, an ophthalmic house surgeon, and a house surgeon for diseases of the throat, nose, and ear are appointed every six months, and are provided with rooms and board and receive a salary of £80 a year. Three resident anæsthetists are appointed annually, and receive salaries of £120, £100, and £100 respectively, with rooms. An extern midwifery assistant is appointed every three months, and receives a salary of £80 a year. The clinical clerks, the obstetric clerks, the clerks to the medical out-patients, the dressers to the surgical in-patients and to the out-patients, and the dressers in the special departments are chosen from the students. A residential college is attached to the hospital.

New Buildings.—The new buildings comprise residential quarters for the resident staff, casualty, medical, surgical, and special out-patient departments, casualty wards, dispensary, and clinical lecture theatre. A new chemical laboratory has been added to the Medical School, and a laboratory devoted to instruction in Public Health. A second new block is devoted to Pathology, and contains the post-mortem room as well as extensive laboratories for bacteriology, clinical pathology, pathological histology, and pathological chemistry. The Medical School Buildings include three large lecture theatres, a large dissecting room, a spacious library (containing 13,000 volumes), a well-appointed museum of anatomy, physiology, comparative anatomy, materia medica, botany, and pathological anatomy. The pathological museum is the most complete in the kingdom. There are laboratories for chemistry, physiology, pharmacology, physics, public health, and biology, giving ample accommodation in every department.

Special Classes for the Primary and Final F.R.C.S. are held twice yearly. *Instruction in Preliminary Science* is given to University of London students in chemistry, biology, and physics throughout the year. *Laboratory Instruction for the D.P.H.* is provided during the winter and summer sessions.

¹ For Ancillary Metropolitan Medical Schools see p. 447.

The recreation ground of 10 acres is at Winchmore Hill for the use of the members of the Students' Union, which all students are expected to join. The Students' Union contains a large reading and smoking room, a committee and writing room, luncheon and dining hall, and a miniature rifle range.

Scholarships given in aid of Medical Study.—At this school various Scholarships, prizes, &c., are given. For five of the Scholarships and the Exhibition—namely, (a), (b), two Entrance Scholarships of the respective values of £75 and £100; (c) Entrance Scholarship in Arts, £100; (d) Jeaffreson Exhibition, £50; and (e) Shuter Scholarship, £50—a full or University course at St. Bartholomew's Hospital is required. The awards of (a), and (b) are made after examination in selections from the subjects of Chemistry, Physics, Zoology, Botany, Physiology, and Anatomy; (c) and (d) are awarded after examination in Latin, Mathematics, and Greek or French or German; (e) is awarded after competitive examination among Cambridge Graduates in Anatomy and Physiology. The remaining Scholarships and prizes are as follows:—Four Junior Scholarships: (f) No. 1, £30, Anatomy and Physiology; (g) No. 2, £20, Anatomy and Physiology; (h) No. 3, £25, Chemistry, Physics, and Biology; (i) No. 4, £15, Chemistry, Physics, and Biology; (j) Senior Scholarship, £50, Anatomy, Physiology, and Chemistry; (k) Kirkes Scholarship, £30 and medal, Clinical Medicine; (l) and (m) two Brackenbury Scholarships, £39 each, one in Medicine and one in Surgery; (n) Sir G. Burrows Prize, £10, Pathology; (o) Skynner Prize, 13 guineas, Regional and Morbid Anatomy; (p) Matthews Duncan Medal and Prize, £20, Midwifery and Gynaecology; (q) Luther Holden Research Scholarship in Surgery, awarded by election, £105; and (r) Lawrence Research Scholarship and gold medal in Pathology, awarded by election, £115.

Information may be obtained on application to the Dean to the Medical School: Dr. T. W. Shore. The Warden of the College is Mr. W. Girling Ball.

CHARING CROSS HOSPITAL.—The Hospital, to which the School is attached, contains 300 beds. Over 3000 cases pass through its wards each year, and some 24,000 out-patients and casualties are treated. There are special departments for Mental Diseases, Midwifery, Diseases of Women, of Children, of the Skin, Eye, Ear, Throat, Nose, and Teeth, for Orthopaedic Cases, X Ray work, and for Electrical Examination and Treatment.

Appointments.—In the Medical School Demonstratorships and Assistant Demonstratorships are open to students of the School. Medical, Surgical, and Obstetric Registrars to the Hospital are appointed annually. Six House Physicians, six House Surgeons, and two Resident Obstetric Officers are appointed each year after competitive examination.

Primary and Intermediate Studies.—By an agreement with the University of London the School sends its Primary and Intermediate Students to receive their lectures and practical work at King's College, which is situated within four minutes' walk. This arrangement has proved successful.

Final Studies.—These are taken in the school and hospital, where systematic lectures, demonstrations, and tutorial classes are arranged to cover all the subjects necessary for qualifying examinations. Departments are also available for other final subjects of Materia Medica, Toxicology, and Operative Surgery.

An Institute of Pathology with a whole-time staff of scientific workers and fully equipped Laboratories has been established in the School. Students receive their training in Preventive Medicine, Pathology, and Bacteriology here, and are encouraged to undertake Research. Special facilities for Post-graduate Research and Study.

The course in Ophthalmology is given in the Royal Westminster Ophthalmic Hospital. Special lectures and demonstrations are arranged for Post-graduates.

The *Museum* contains over 4000 specimens, including a notable collection of over 800 gynaecological specimens, "The Cuthbert Lockyer Collection."

Students' Club.—The social comfort and convenience of students are met by library, reading, and smoking-rooms, refreshment-room, &c. The Club, which is under the control of a Committee of Students, provides needful athletic recreation, and includes the Medical Society.

Women Students.—Women students are accepted by the School and Hospital upon the same terms and conditions as

men, and after qualification are eligible for resident Hospital appointments. A separate common-room and a female attendant are provided, but beyond this no further distinction is made. This system of co-education, under which men and women are placed on terms of complete equality throughout the whole of the curriculum, has been found to work successfully and to their mutual advantage.

Fees.—An entrance fee of 10 guineas and 8 guineas is payable by full-course and final-course students respectively, and an annual fee of 35 guineas covers all other expenditure, with the exception of 7 guineas for vaccination, dispensing, and fever hospital attendance, which must be taken outside the hospital. Membership of the Students' Club is included in these fees.

Further information may be obtained on application to the Dean, Dr. W. J. Fenton, Medical School, Charing Cross Hospital, London, W.C.

ST. GEORGE'S HOSPITAL.—This hospital has a service of 436 beds, of which 180 are allotted to surgical, 150 to medical cases, and 100 are at the Convalescent Hospital at Wimbledon. One ward is set apart for Diseases Peculiar to Women. Children's beds are placed in all the women's wards. Two wards are allotted to ophthalmic cases.

Entrance Scholarships and Endowed Prizes of a total value of £576 are awarded annually; a detailed list is placed below. The entire teaching and laboratories are now devoted to purely clinical subjects, and arrangements have been made with the University of London for students who enter during the first, second, or third year of the curriculum as students of St. George's to carry out the necessary courses of instruction at either University College or King's College. Students then complete their course, without payment of any entrance fee, in a school entirely devoted to Clinical work.

Eight house physicians and eight house surgeons are appointed annually. Special attention is directed to the following paid appointments, among others, which are open to students after they have held house office:—Resident Assistant Physician and Resident Assistant Surgeon, at £350 per annum each; Medical Registrarship at £200 per annum; Surgical Registrarship at £200; Assistant Curatorship of the Museum at £100; Obstetric Assistantship (Resident) at £50; the post of Resident Anaesthetist at £100; the posts (2) of Senior Anaesthetists at £50; the posts (2) of Junior Anaesthetists, each at £30. The St. George's Hospital Club, with smoking- and luncheon-rooms on the hospital premises, and an athletic ground at Wimbledon, is an amalgamation of the Hunterian Society, the *Gazette*, and the chess, lawn tennis, boxing, hockey, rifle, and golf clubs. Students have the advantage of a library of medical and scientific books which is kept up to date.

Scholarships and Prizes.—At this school two entrance scholarships are given, the money value and the subjects of examination being as follows: (a) and (b) two University Entrance Scholarships, 70 guineas and £50 respectively, Anatomy and Physiology. The others are as follows: (c) William Brown Exhibition, tenable for two years and open to perpetual pupils having registrable qualifications, £135 per annum, Practice of Medicine, Midwifery, and Surgery; (d) William Brown Exhibition, tenable for three years and open to perpetual pupils qualified not more than three years previously, £45 per annum, Essay and Original Work; (e) Allingham Scholarship in Surgery for Students qualified not more than three years, £60, Competitive Essay; (f) and (g) two Brackenbury Prizes, one in Medicine and one in Surgery, £30 each, open to students of not more than five years' standing; (h) H. C. Johnson Memorial Prize, £15, Practical Anatomy; (i) Pollock Prize, £17, Physiology, Physiological Chemistry, and Histology; (j) Clarke Prize, £5; (k) Thompson Medal, £5, Clinical Reports; (l) Brodie Prize, £7, Clinical Reports; (m) Webb Prize, open to perpetual pupils, £30, Bacteriology; (n) Sir Francis Laking Memorial Prize, £65, open to students having registrable qualifications.

Further information may be obtained from the Dean of the Medical School, Mr. R. R. James.

GUY'S HOSPITAL.—This hospital, founded by Thomas Guy in 1721 for the reception of 400 patients, and enlarged through the aid of a large bequest from the late William Hunt, contains at the present time 644 beds. The

school buildings have been rebuilt and now offer very complete accommodation. Within the grounds of the hospital are situated the residential college, with accommodation for 60 students, the students' club, with reading, smoking, luncheon, and dining-rooms, a fives court, and swimming bath. The athletic ground and club house is situated at Honor Oak Park, and can be reached in 20 minutes from the hospital.

House physicians, house surgeons, out-patient officers and assistant house surgeons, obstetric residents, ophthalmic house surgeons, clinical assistants, clerks to anaesthetists, surgeons' dressers, medical clinical clerks, post-mortem clerks, extern obstetric attendants, and dressers and clerks in the special departments are appointed from among the students upon the recommendation of the Medical Council according to merit. The establishment of a Venereal Clinic, in accordance with the Scheme of the Local Government Board and London County Council. Lectures and clinical instruction are given, to which Medical Students and Practitioners are admitted without fee.

A Post-graduate Course is held in connexion with the Fellowship of Medicine.

The following new Clinics have been opened: Salomon's Welfare Centre (for Maternity and Children), Tuberculosis Department, and V.D. Department.

Scholarships.—Seven entrance scholarships are awarded annually as follows:—(a) one War Memorial scholarship, providing a free Medical Education for five years—the annual value is about £40, to be awarded either in Arts or in Science, according to the discretion of the Examiners and to the percentage of the marks obtained; (b) one Arts scholarship of £100 for students under 21 years of age, Latin, English, Greek or French or German, Arithmetic, Euclid, and Algebra; (c) one Science scholarship for students under 21 years, £120, Inorganic Chemistry, Physics, and Biology; (d) a Scholarship of £50, open to candidates under 21 years of age, to be awarded either in Arts or in Science, according to the discretion of the Examiners, and to the percentage of the marks obtained; (e) three scholarships, one of £80, one of £75, and one of £35, for students under 25 years of age who have completed the curriculum for, or passed the examination in, Anatomy and Physiology for a medical degree in any University of the British Empire, and have not entered as students in any Metropolitan Medical School. Subjects: Any two of the following: Anatomy, Physiology, Pharmacology, General Pathology, Organic Chemistry.

In agreement with the practice of the Universities, an allowance will be made (1) for Military Service performed by candidates, the term "military service" meaning service in the Naval or Military Forces of His Majesty or of His Majesty's Allies during the war; or (2) in respect of other approved duties in connexion with national defence.

The Dean of the Medical School is Professor T. B. Johnston, from whom further information may be obtained.

UNIVERSITY OF LONDON: KING'S COLLEGE.—The medical department (Faculty of Science, Medical Division) at this College only deals with Preliminary and Intermediate subjects, and instruction in these subjects is given in the College laboratories by university professors and their assistants. The following four hospital schools prepare their students only for the final examinations—viz., King's College Hospital, Westminster Hospital, St. George's Hospital, and Charing Cross Hospital—sending them to King's College for the earlier part of the curriculum. The department is open to both men and women.

Fees.—(a) Entrance fee, £6. (b) Tuition fee of 12 guineas per term, or a composition fee of 35 guineas per annum if paid at the commencement of the session, or a composition fee of 100 guineas for the three years' course if paid at the commencement of the course. For prospectus and further information application should be made to the Dean of the department (Professor E. Barclay-Smith).

KING'S COLLEGE HOSPITAL MEDICAL SCHOOL.—The advanced subjects in the curriculum are dealt with at the Medical School attached to King's College Hospital, which is situated at Denmark Hill, S.E. The hospital stands in the midst of a South London population, from which an immense amount of clinical material is forthcoming. During the past year there were 174,626 attendances in the

out-patient and casualty departments. There are 400 beds available for in-patients, and provision will ultimately be made for 600 beds. There are special departments for Bacteriology, Children, Clinical Pathology, Dermatology, Gynaecology and Obstetrics, Laryngology, Massage, Neurology, Odontology, Ophthalmology, Orthopaedics, Otolaryngology, Physiotherapy, Psychological Medicine, Radiology, Rhinology, and Urology, each in charge of a specialist and his staff. Clinics are also held in applied pharmacology, cardiology, and medical chemistry. The appointments open to students are those of senior clinical assistant to the special departments; medical, surgical, and obstetric tutorships; resident casualty officers; resident anaesthetist; bacteriologist; clinical pathologist; pathological registrar; and medical, surgical, and obstetric registrarships. Fifteen resident medical and surgical officers are appointed half-yearly.

Scholarships and Prizes.—For the first two scholarships in the list here shown a complete course at King's College is required. The money value and subjects of examination are as follows:—(a) Two Warneford Scholarships, tenable for four years, £25 each per annum; (b) Sambrooke Scholarship, £50; (c) Rabbeth Scholarship, £20; (d) Medical Entrance Scholarships, £50, Anatomy and Physiology, and, £50, Pathology and Pharmacology, open to students who (1) propose to take a degree at any British University, and have passed their University examination in Biology, Chemistry, and Physics, and who (2) will become students at King's College Hospital from date of entering upon Scholarship; (e) Two Medical Entrance Scholarships one in Arts and one in Science, £50 each, tenable for five years, successful candidates to study at King's College and King's College Hospital; (f) Three Medical Scholarships, £40 for fifth-year students, £20 for third-year students, and £20 for second-year students; (g) Two Sambrooke Registrarships, open to matriculated students who have filled certain appointments in hospital, £50 each; (h) Carter Prize, £15, Botany; (i) Tanner Prize, £10, Obstetrics and Diseases of Women; (j) Todd Prize, £4 4s. and medal, Clinical Medicine; (k) Two Burney Yeo Entrance Scholarships, £80 each, open to students of Oxford and Cambridge on the nomination of the Regius Professors.

Athletics.—The King's College Hospital Clubs and Societies Union was formed in 1908, and consists of the Listerian and Musical Societies, the Students' Common Rooms, and the various athletic and sports clubs. Admirable playing fields, over six acres in extent, have been provided for the use of the students on Dog Kennel Hill, Lordship-lane, S.E., about ten minutes' walk from the hospital. There are also Tennis Courts in the grounds of the Hospital and of "The Platanes," the hall of residence for students belonging to the hospital.

Fees.—The composition fee for Hospital work and Final subjects of the curriculum is 93 guineas if paid in one sum, or 95 guineas if paid in two instalments, in addition to the Entrance Fee of 10 guineas. Dean: Dr. H. Willoughby Lyle. Secretary of the Medical School: Mr. S. C. Ranner, King's College Hospital, Denmark Hill, S.E. 5.

LONDON HOSPITAL.—The hospital, with its Medical College and Dental School, is situated in the Mile End-road, E. The hospital contains 933 beds, which are in constant use, and is the only general hospital for East London. During last year 19,699 in-patients and 118,685 out-patients received treatment, while 7793 major operations were performed. 37,006 out-patients attended the special departments for diseases of the Eye, Ear, Nose and Throat, Skin, Teeth, &c., and the Obstetric, Orthopaedic, Venereal, Radiographic, Electro- and Physico-Therapeutical and Inoculation Departments. The hospital presents, therefore, a large field for clinical instruction, and in its Wards and Out-patient Departments exceptional opportunities are afforded for acquiring an extensive and practical experience in all phases of disease.

The Clinical Units in Medicine and Surgery coördinate the teaching of their subjects in the Hospital. The directors and their assistants give practical instruction in Elementary Clinical Medicine and Surgery to all students before they are allowed to enter the Wards and Out-Patient Department. Senior Students are encouraged to work with the units. Special courses of lectures and demonstrations are arranged in Medicine and Surgery and their ancillary subjects. Opportunities for research will be provided under the supervision of the staffs of the units.

Owing to the large number of patients more appointments are open to students before and after qualification than at any other hospital. Holders of resident appointments have free board. Special classes are held for the examinations of the University of London, for the Fellowship of the Royal College of Surgeons, and for other higher examinations. Special entries for medical and surgical practice can be made. A residential Hostel on hospital grounds is provided for the convenience of students. The Clubs Union Athletic Ground of over 13 acres is within easy reach of the hospital.

Scholarships and Prizes.—At this school the successful candidates for the first items in the list here shown must enter for the course subsequent to passing the first examination in Biology, Chemistry, and Physics. The value and the subjects of examination are as follows:—Price Scholarship £100, and one Entrance Scholarship of £50, subjects of First Medical Examination at the University of London; Epsom College Scholarship, free education, subjects of First Medical Examination as above; Price Scholarship, open to students of Oxford and Cambridge Universities, £52 10s., Human Anatomy and Physiology; Buxton Scholarship, £31 10s., subjects of Anatomy and Physiology; three Scholarships for Clinical Work, £20 each, Medicine, Surgery, and Obstetrics and Gynaecology; Sutton Prize, £20, Pathology; Duckworth Nelson Prize, biennial, £10, Practical Medicine, and Surgery; Letheby Prizes (2), £25, Chemistry and Chemical Pathology; eight Dressers' Prizes, amounting to £40, zeal, efficiency, and knowledge of Elementary Clinical and Minor Surgery; Hutchinson Prize, triennial, £40, Clinical Surgery; two Practical Anatomy Prizes, £6 and £4 respectively; Andrew Clark Prize, biennial, £26, Clinical Medicine and Pathology; James Anderson Prizes, £9, Elementary Clinical Medicine; Forensic Medicine; Arnold Thompson Prize, £15, Medical and Surgical Diseases of Children; and Liddle Prize, triennial, £120.

Medical Research Funds.—Research Funds of over £26,000, including the Eliza Ann Alston Endowment Fund for Medical Research, provide valuable scholarships for men wishing to undertake research or desirous of preparing Theses for University degrees.

Dean: Professor William Wright, London Hospital Medical College, E.

ST. MARY'S HOSPITAL.—305 beds. The number of in-patients treated during 1919 was 3591. The number of out-patients was 15,833 with 21,802 casualty cases, a total of 37,635. The situation of the hospital and Medical School in the centre of the residential districts of Paddington, Bayswater, and North Kensington renders it exceptionally convenient for students' rooms, a register of which is kept by the authorities for the use of students.

Laboratories, &c.—The Medical School provides for the entire curriculum. Special laboratories are in use for Biology, Chemistry, and Physics, a series of lecture theatres and laboratories for Anatomy and Physiology, and a spacious and well-lighted dissecting-room. The Pathological Department is under the direction of Dr. E. H. Kettle, and a block of consulting-rooms and laboratories in the New Wing of the Hospital has been equipped for the department of Therapeutic Inoculation.

Appointments.—All clinical appointments in the hospital are free to students of the Medical School and the resident medical officers are chosen by competitive examination. Six house physicians, six house surgeons, four obstetric officers are appointed in each year and receive board and lodging in the hospital. Two resident anaesthetists are appointed in each year and receive a salary at the rate of £100 per annum, with board and lodging. Four casualty house surgeons are appointed in each year upon the same conditions. Several assistants in the department of Therapeutic Inoculation are appointed annually at salaries of £100 per annum and upwards. In addition to the above, the senior appointments, medical, surgical, and obstetric registrar, casualty physician, demonstrator of anatomy, physiology, and biology, are made annually.

Clinical Facilities.—The clinical teaching has recently been greatly extended by the introduction of Clinical Units in Medicine and Surgery, and by the affiliation, for teaching purposes, of the Paddington Infirmary, Paddington Green Children's Hospital, and Maida Vale Hospital for Nervous Diseases, bringing up the total number of beds available for teaching purposes to more than 1000.

Clubs, &c.—The amalgamated clubs include all the various athletic clubs, as well as the Medical Society, &c. There is a students' club on the Hospital premises, the membership of which is included in the amalgamated clubs.

A new athletic ground (10 acres) has been obtained at Wembley and is now in use.

Special Tuition.—Special tuition is provided for the Intermediate and Final Examinations of the Universities of Oxford, Cambridge, and London, and for the Primary and Final F.R.C.S.

The composition fee for full students is £200 if paid in one sum, or £210 if paid in four instalments. University students who have completed their examinations in Anatomy and Physiology are admitted on payment of a composition fee of 90 guineas paid in one sum or by payment of two annual instalments of 50 guineas and 45 guineas respectively. A system of annual fees is also in force as an alternative to composition fees. Separate courses of lectures, laboratory work, or hospital practice may be taken.

Scholarships and Prizes.—The money value and subjects of examination of these are as follows: (a) and (b) Entrance Scholarships in Natural Science, £100 and £50 respectively, awarded by competition in September; (c) the Frederic John Palmer Scholarship in Natural Science, £25; (d) University Scholarship in Natural Science, open to members of Oxford or Cambridge University, £52 10s.; (e) University Scholarship in Natural Science, open to members of any British University, £52 10s.; (f) Epsom Scholarship, awarded by nomination, £52 10s.; (g) Gold Medal, £20, an Essay on Some Special Point in Clinical Medicine; (h) Meadows' Prize, awarded in alternate years, £8, Obstetrics; (i) Wallace Memorial Prize and Medal, for work in Vaccine Therapy, £5 5s.; (j) David Lees Prize in Clinical Medicine, £8; (k) Sir William Broadbent Prize in Clinical Medicine, £8.

Dean: Sir John Broadbent, M.D. Secretary: Mr. B. E. Matthews, St. Mary's Hospital Medical School, Paddington, W.

MIDDLESEX HOSPITAL.—The Hospital contains over 450 beds, with special wards for Cancer, Maternity, and Gynaecological and Ophthalmological cases, and for Diseases of Children. The Cancer Charity, containing 92 beds and Special Investigation Laboratories, offers unrivalled opportunities for the study of Cancer, both in its clinical and pathological aspects.

In the Electro-Therapeutic Department (under the direction of the Professor of Radiology) students obtain instruction in the Treatment of Lupus and Cancer by the X Ray method of treatment. An Electrocardiograph Department is also established.

The Medical School, which now includes the Bland-Sutton Institute of Pathology and the Cancer Research Laboratories is fully equipped for the theoretical and practical teaching of all the subjects of the medical curriculum, and for the Diplomas in Public Health, for which two courses are held yearly, commencing in April and October. Ample laboratory and class-room accommodation is provided. The teaching staff includes 6 Professors, 29 recognised Teachers, 6 Demonstrators, 3 Tutors.

The Bland-Sutton Institute of Pathology is completely equipped for routine investigation, teaching and research work, and contains a new lecture theatre and large pathological, bacteriological, and clinical laboratories, also smaller laboratories for individual research work. A well-equipped Anatomical and Pathological Museum and Reference Library offer every facility for study.

Other features of interest are: The institution of a course in Medical Radiology and Electrolgy, under the direction of the Professors of Radiology and Physics. The D.P.H. course, under the direction of Dr. Charles Porter, M.O.H., St. Marylebone, will commence on Oct. 1st. Primary F.R.C.S. class will resume on Sept. 1st. Final F.R.C.S. class begins on Sept. 1st.

Special classes are held to prepare students for the Intermediate examinations of the Universities. There is a Residential College in the hospital for students.

Hospital Appointments.—All appointments are made without fee of any kind, and the following are appointed at intervals annually: six house physicians, eight house surgeons, two obstetric and gynaecological house surgeons, two casualty medical officers, two casualty surgical officers, one resident anaesthetist, and two resident officers to the

special departments. The medical and surgical casualty officers are appointed twice a year. The medical, surgical, and obstetric and gynaecological registrars are appointed as vacancies arise.

Non-resident qualified clinical assistants are appointed to assist in the various out-patient departments. Clinical clerks and surgical dressers are also appointed in every department.

Scholarships, Prizes, &c.—(a), (b), and (c) Three Entrance Scholarships, value £100, £50, and £25, and (d) a University Scholarship, value £50, are awarded annually in September. The successful candidates are required to become general students of the school. (e) A Freer Lucas Scholarship for Foundationers or Council Exhibitioners of Epsom College is awarded annually on the nomination of the Headmaster. There are also, (f) and (g), two Broderip Scholarships, value £60 and £40 respectively; (h) the Lyell Gold Medal and Scholarship, value £55 5s.; (i) the John Murray Medal and Scholarship, value £25 (awarded every third year); (k) the Freeman Scholarship, value £30; (l) the Hetley Clinical Prize, value £25; (m) the Leopold Hudson Prize, value 11 guineas; and (n) the Second Year's Exhibition, value 10 guineas. There are also numerous class prize examinations.

In connexion with the Cancer Research Department the following Scholarships are awarded:—Richard Hollins Research Scholarship, value £100; Walter Emden Scholarship, value £100; and a Cancer Research Scholarship, value £60.

Fees.—The fees are arranged on a basis of an annual payment of £42 for the five years of the curriculum. After five years, if the student is not qualified, the annual fee is £21.

The Amalgamated Students' Club includes the following: the Medical Society, the Common Room Society, the cricket club, the football clubs, the athletic club, the rowing club, the musical society, the chess club, the lawn tennis club, and the hockey club. A subscription to the Amalgamated Students' Club is payable by all General and Dental students. Full particulars on application to the Dean, Middlesex Hospital Medical School, W. 1.

ST. THOMAS'S HOSPITAL.—This hospital received its present charter from King Edward VI., but as a monastic institution was in existence prior to the year 1207. The building occupies a unique position by the river, opposite the Houses of Parliament, and contains 632 beds. The in-patients last year numbered 7687, whilst the number of attendances as out-patients, including the casualty and light departments, was 331,278. There are special departments for the treatment of women, children, the eye, ear, nose and throat, skin, and teeth. The Tuberculosis Department forms a part of the Lambeth scheme for treatment of patients and for instruction. The Venereal Department has been established as part of the London County Council scheme. Departments for light treatment, X rays, and the Physio-therapeutic Department are also special features. A speech clinic has been inaugurated in connexion with the Children's Department. Exceptional facilities are offered in the hospital laboratories for the study of general pathology, clinical pathology, chemical pathology, cardiology, and of treatment by serums and vaccines. Surgical operations take place in the main theatres every day except Saturdays at 2 P.M. Clinical teaching in the wards, out-patients' and special departments, is available every day of the week. Clinical lectures are delivered every Wednesday during the sessions. All appointments in the hospital are open to students without extra fee. Clinical assistants to all the special departments are appointed every three months. A resident assistant physician and a resident assistant surgeon, at a salary of £200 each, are appointed biennially; also four hospital registrars (medical, surgical, obstetric, and ophthalmic), the two former receive a salary of £250 and the latter £50. Three assistants in the clinical laboratory are paid, one at the rate of £400, and two at £250 each, per annum. There is also an assistant in the laboratory for chemical pathology, paid at a salary of £200. Appointments open to students before qualification: Clinical clerks and dressers for in- and out-patients are selected from students who have completed their third year's work. Every student acts as clerk in the post-mortem room and in one of the pathological laboratories, takes his turn on maternity duty under proper supervision

in the maternity ward, thus obviating any necessity for seeking instruction elsewhere. Students are instructed in the administration of anaesthetics by one of the hospital anaesthetists. The Students' Club comprises a spacious restaurant and smoking and reading room. There is no occasion for students to leave the hospital buildings during working hours. The curriculum is arranged to meet the requirements of all the Examining Bodies. Special classes are held for the examinations at the University of London and for the First and Final Fellowship Examinations of the Royal College of Surgeons of England. Tutorial classes in all subjects precede the various examinations. The hospital is easily accessible from all parts.

Fees.—The annual fees are: for first year (preliminary subjects) £25, and for each subsequent year £50. These fees cover all tutorial classes, but do not include instruction in infectious fevers, pharmacy, and vaccination. Qualified practitioners are permitted to attend the hospital practice on terms which may be ascertained from the medical secretary.

Scholarships and Prizes.—At this school there are five Entrance Scholarships—namely, two in Arts, equivalent to the tuition fees for the first medical examination; two in Natural Science, of the value of £150 and £60 respectively; and the University Scholarship of £100 in Anatomy, Physiology, and Chemistry. The value of all entrance scholarships must be taken out in tuition fees. The money value and subjects of examination of the remainder are as follows: (a) William Tite Scholarship for second-year students, £25; (b) and (c) Musgrove Scholarship or (alternately) Peacock Scholarship, each for third-year students and tenable for two years, £35 each; (d) Cheselden Medal, Surgery and Anatomy; (e) Mead Medal, Medicine, Pathology, and Hygiene; (f) Toller Prize, Medicine, Pathology, and Hygiene; (g) Bristowe Medal, Pathology and Morbid Anatomy; (h) Solly Medal and Prize, biennially, Surgical Reports; (i) Treasurer's Gold Medal for the most distinguished fifth-year student; (j) Wainwright Prize, Medicine, Pathology, and Hygiene; (k) Hadden Prize, Pathology; (l) Beane Scholarship, £50 biennially, Surgery and Surgical Pathology; (m) Sutton Sams Prize, biennially, reports of cases in Obstetric Medicine; (n) Grainger Testimonial Prize, £31 10s. Anatomy and Physiology; (o) Louis Jenner Research Scholarship, tenable for two years, £60 annually, Pathology; and (p) Research Scholarship, tenable for two years, £200 per annum.

The Dean of the Medical School is Sir Cuthbert S. Wallace, the Sub-Dean Dr. C. R. Box, and the Medical Secretary Dr. A. Elliot, from whom any further information may be obtained.

UNIVERSITY OF LONDON, UNIVERSITY COLLEGE.—University College has been constituted a University centre for the teaching of medical sciences. The College Faculty of Medical Sciences comprises the Departments of Physics, Chemistry, Botany, and Zoology (the Preliminary Medical Sciences); also the Departments of Anatomy, Physiology, and Pharmacology (the Intermediate Medical Sciences), and the Department of Hygiene and Public Health (Post-graduate Study).

Faculty of Medical Sciences.—Composition fees.—For the courses required by the University of London. 1. For the First Medical Course, 35 guineas, entitling to one attendance and to the privileges of the Union Society for one session. 2. For the Second Medical (Intermediate) Course 80 guineas, payable in two instalments of 40 guineas each. This fee entitles to attendance at Anatomy and Physiology during three years and to one attendance at Organic and Applied Chemistry, Pharmacology, and Materia Medica, and to the privileges of the Union Society for two sessions.

For the medical education required by the Examining Board in England and the Society of Apothecaries. First examination, Parts I., II., III., 29 guineas, entitling to attendance for the First and Second Terms and to the privileges of the Union Society for one session; 35 guineas, entitling to attendance throughout the session and to the privileges of the Union Society for one session. First Examination, Part IV., and second examination, 80 guineas, payable in two instalments of 40 guineas each. This fee entitles to attendance during three years in all subjects

but Practical Pharmacy and to the privileges of the Union Society for two sessions.

Scholarships and Prizes.—The first three items on the present list require a complete intermediate course at University College. The money value and subjects at examinations are as follows: (a) The Bucknill Scholarship, 135 guineas; (b) and (c) two Entrance Exhibitions, 55 guineas each, Chemistry, Physics, Botany, and Zoology; (d) Cluff Memorial Prize, £15 biennially, Anatomy, Physiology, and Chemistry; (e) Schäfer Prize in Physiology, £18 triennially; (f) Sharpey Physiological Scholarship, £105, Biological Sciences; (g) Morris Bursary for sons of deceased professional men, by nomination, tenable for two years, £16 a year; and (h) five Gold and five Silver Medals awarded annually in various departments.

Women students are admitted.

UNIVERSITY COLLEGE HOSPITAL MEDICAL SCHOOL.—Dean: Dr. G. F. Blacker. Vice-Dean: Dr. A. M. H. Gray. Secretary: G. E. Adams. Open to men and women students. Fees for Preliminary and Intermediate Course: See under University College. For the Final M.B., B.S. (London) Course, 112 guineas if paid in one sum, 115 guineas if paid in two instalments, as follows—first year, 70 guineas; second year, 45 guineas. This fee entitles to attendance on Lectures and Hospital Practice during three years and to one attendance on Practical Pathology and Practical Surgery. Vaccination and attendance at a Fever Hospital are not included. This course of instruction is also suitable for the corresponding examinations at the Universities of Oxford, Cambridge, and Durham, and for the medical education required by the Examining Board in England and the Society of Apothecaries.

There are over 300 beds in the hospital.

Medical and Surgical Unit.—Whole-time Directors of medical and surgical units have recently been appointed. They are responsible for the systematic teaching of the principles of medicine and surgery and are assisted by whole-time assistants. The teaching of practical medicine and surgery and of their special branches continues to be conducted by the honorary staff of the hospital.

The school has recently been the recipient of a large donation from the Rockefeller Foundation, which will enable it largely to increase its facilities for clinical and pathological study and also to establish an obstetrical unit on similar lines to those of medicine and surgery.

Special Departments, Clinical and Laboratory Facilities.—Those who are desirous of carrying out original research in Pathology, including Morbid Anatomy, Bacteriology, Experimental Pathology, and Chemical Pathology, are admitted to work in the laboratories of the school by the Professor of Pathology, and under certain conditions can receive grants from the Charles Graham Medical Research Fund. A special course of instruction is given in conjunction with University College for preparation for the examinations for Diplomas in Public Health of the various universities and examining bodies. In the Dental School in Great Portland-street, formerly known as the National Dental Hospital, there is afforded the opportunity for attending lectures and practical instruction in diseases of the mouth and teeth.

Appointments tenable by Students.—Clerkships and dresser-ships to the physicians, surgeons, anaesthetist, and pathologist are allotted amongst the students of the hospital. Maternity students are appointed each month and reside in the Students' House connected with the Medical School and Hospital. Eight house physicians and house surgeons, four senior and four junior obstetric assistants, are selected annually by examination from among the senior students who have a medical qualification. The house physicians and house surgeons reside free in the hospital for six months, and the senior obstetric assistants for three months. In addition to these posts there are certain special appointments which are vacant from time to time and are filled by senior students of the hospital: 1. The Resident Medical Officer. This officer is appointed for a period of two years and is chosen from amongst the more senior recent residents of the hospital. 2. The two Surgical Registrars are also chosen from among the more senior recent residents of the hospital. 3. The Obstetric Registrar. 4. Two Casualty Medical Officers and a Casualty Surgical Officer are appointed, each for a period of six months. 5. Assistant in Ear and Throat Department, appointed for one year. 6. Assistant in

Ophthalmic Department, appointed for one year. 7. Registrar in Anaesthetic Department, appointed for one year. 8. Deputy Anaesthetists. During the absence of one or another of the Anaesthetists in the summer months a senior qualified student is appointed as a substitute and is granted a special certificate.

Museum of Pathological Anatomy.—The Museum is open for study from 9 A.M. to 5 P.M. Microscopic sections of most of the specimens in the Museum have been prepared and are available for the use of students on application to the Curator. The Museum contains 1100 admirable paintings by Sir Robert Carswell and Sir Charles Bell and a collection of old surgical instruments formerly belonging to Robert Liston.

The Anatomical Museum of the University of London, University College, is open to all students of University College Hospital and Medical School on the recommendation of the School Committee.

The Medical Library is open daily for the purposes of study to every student of the Medical School from 9 A.M. to 5 P.M., Saturdays 9 A.M. to 1 P.M. It contains about 13,500 works on medical subjects, including all the current text-books and works of reference required for study or research.

The Medical Society of University College Hospital Medical School exists for the dual purpose (1) of promoting the study of Medical and Surgical Science, and (2) of promoting social intercourse among its members. All Students of the Medical School are eligible for membership. Meetings are held once a fortnight for the purpose of discussing subjects connected with the study of medicine. In its social aspect the society includes various athletic clubs and superintends the gymnasium and squash racquet court in the Medical School. The Athletic Ground, which is used in conjunction with the Union Society of the University of London University College, is situated near the Great Western Railway station at Perivale.

Scholarships and Prizes.—At this School the first two Scholarships (a) and (b) entitle the holder to a complete course at University College and University College Hospital Medical School; the second two (c) and (d) entitle to a final course at the Medical School. The money value and subjects of examination are as follows:—(a) Entrance Scholarship, Bucknill, 167 guineas, Chemistry, Physics, Botany, and Zoology; (b) Epsom Free Medical Scholarship, subjects of Preliminary Scientific Examination and Nomination by Epsom College; (c) and (d) two Goldsmid Entrance Exhibitions, 112 guineas each, Anatomy and Physiology; (e) Graham Scholarship in Pathology, £400 per annum for two years, awarded by the Senate of the University of London; (f) Atkinson Morley Scholarship, tenable for three years, £45 per annum, Surgery; (g) Atchison Scholarship, tenable for two years, £55 per annum; General Proficiency in Medical Studies; (h) Magrath Clinical Scholarship, about £100, Clinical Cases; (i) Percival Allyn Scholarship, about £60, Surgery; (j) Filliter Exhibition, £30, Pathology; (k) Erichsen Prize, £10 10s., Practical Surgery; (l) two Senior and two Junior Fellowes Clinical Medals for Clinical Medicine; (m) two Liston Gold Medals for Clinical Surgery; (n) Alexander Bruce Gold Medal for Pathology and Surgery; and (o) Tuke Silver and Bronze Medals for Pathology. (p) Radcliffe Crocker Travelling Scholarship for Dermatology. (q) Leslie Pearce Gould Travelling Scholarship for Surgery.

Residence of Students.—University College Hall, Ealing, is recognised by the Medical School authorities as a residential hostel. The Students' House in University-street contains large and comfortable rooms. The Maternity Students occupy them on payment of a moderate charge. Gentlemen who desire assistance in their studies should consult the Dean or Lecturers.

WESTMINSTER HOSPITAL.—The hospital contains 215 beds and affords relief to upwards of 2000 in-patients and 15,000 out-patients annually. There are separate departments for Diseases of the Eye, Ear, Skin, Teeth, and Throat, for Orthopaedic practice, for Diseases of Women, for Diseases of Children, for Radiography, and for the Light Treatment. The Anatomical, Pathological, and Materia Medica Museums are open to all students of the school.

The usual registrarships and house appointments are open to male and female students.

By a scheme for the concentration of the teaching of the preliminary and intermediate subjects of the curriculum, which has the support of the London University, an arrangement has been made by the Westminster School for the teaching of these subjects at King's College. Students, however, may join the Westminster Medical School as formerly and may compete for Entrance Scholarships as heretofore.

Scholarships and Prizes.—The following Entrance Scholarships are offered for competition: Winter Session: (a) Arts Scholarship, the "Guthrie," £60. (b) Science Scholarships: Natural Science Scholarship, £60; Chemistry and Physics Scholarship, £30; and Two Scholarships in Anatomy and Physiology, £50 each. Summer Session: Two Scholarships in Anatomy and Physiology, £50 each. During the period of study the following prizes may be competed for: Sturges Prize in Clinical Medicine, about £6, Notes of Cases; Clinical Surgery Prize, £5, Notes of Cases; Chadwick Prize £21 in books or instruments—Medicine and Surgery, including Pathology and Applied Anatomy and Physiology; Frederic Bird Medal and Prize, open to Fourth-year Students, £14 in medal and books or instruments—Midwifery, Diseases of Women, Medicine, Pathology, Forensic Medicine and Bacteriology, and Public Health and Toxicology; Abrahams Prize in Clinical Pathology, 5 guineas, a Paper and Tests in Practical Work; Alfred Hughes Memorial Prize, open to Second-year Students, about £5 in books or instruments—Anatomy; Huxley Memorial Prize, 3 guineas in books or cash, open to Second-year Students—Physiology; Carter Gold Medal and Prize for Botany, open to Students of not more than three years' attendance, gold medal and books of the joint value of £15; Jelf Medal awarded to Third-year Students; Second-year Scholarship, £20, Elementary Anatomy, Physiology, Histology, and Organic Chemistry; Daniell Scholarship, tenable for two years, £20, Chemistry; Rabbeth Scholarship, open to First-year Students, £20, Class Examinations in the Preliminary Scientific Course; and the Sambrooke King's College Scholarship in Science, value £25.

The Dean is Dr. A. S. Woodwark, to whom inquiries may be addressed.

LONDON (ROYAL FREE HOSPITAL) SCHOOL OF MEDICINE FOR WOMEN, 8, Hunter-street, Brunswick-square, W.C.—The fee for the medical course for the degrees of the University of London and for the diplomas of the Royal Colleges of England and for other qualifications is £240 in five instalments. This sum includes library and laboratory fees.

The Royal Free Hospital contains 237 beds. Students also attend the in-patient and out-patient practice of the Elizabeth Garrett Anderson Hospital, Cancer Hospital, Hospital for Sick Children, Great Ormond-street, National Hospital for Paralysed and Epileptic, and Brompton Chest Hospital.

An agreement has been made under which students of the school attend full clinical courses at St. Mary's Hospital, Paddington (305 beds).

Special courses are arranged for the Primary Fellowship Examination of the College of Surgeons; also for dental students in conjunction with the London Dental Hospital, Leicester-square, and the National Dental Hospital.

Students after qualification can hold the posts of house physician, house surgeon, obstetric assistants, clinical assistants, assistant anaesthetist, medical, gynaecological, and surgical registrars, assistant pathologist, and museum curator; and at the Medical School the posts of demonstrators in the departments of Anatomy, Physiology, Pharmacology, Biology, Chemistry, and Physics. Many other resident posts in London and elsewhere are also open to them.

The School buildings have been entirely rebuilt in recent years, and there are spacious, well-equipped laboratories, which afford every facility for efficiency of teaching and practical work in all departments.

There are residential chambers at 8, Hunter-street, 25, Gordon-square, 16, Brunswick-square, and 36, Tavistock-square, and the Warden can be consulted on the subject of other residences for students. The Students' Union arranges the social, athletic, and other clubs and societies.

Scholarships and Prizes.—(a) Isabel Thorne Scholarship, £30. (b) St Dunstan's Medical Exhibition, £60 a year,

tenable for three or five years. (c) Mrs. George M. Smith Scholarship, £50 a year, tenable for three or five years and next to be awarded in 1921. (d) Bostock Scholarship, tenable for two or four years, and next to be awarded in June, 1923, £60. (e) Mabel Sharman-Crawford Scholarship, tenable for four years, £20 a year. (f) Sir Owen Roberts Scholarship, £75 a year for four years. (g) Mabel Webb Research Scholarship, tenable for one year and renewable, £30, Physiology, Chemistry, or Pathology. (h) Fanny Butler Scholarship, tenable for four years; next award in July, 1922, £14 10s. (i) John Byron Bursary, tenable from two to four years, for students already in the School requiring assistance for the prosecution of their medical studies, application to the Secretary by March 31st; next award in March, 1921, £20. (k) Ellen Walker Bursary tenable for two years, awarded to a student beginning fourth year of medical study, £25 a year. (l) Helen Prideaux Scholarship, awarded every second year to a student who has become qualified during the two years immediately preceding the award, and to be spent in assisting the holder to further study, £40. (m) Agnes Guthrie Bursary, value £50, is offered annually to students who desire to pursue a full course of study for the Licentiate in Dental Surgery. (n) Dr. Edith Pechey Phipson Post-graduate Scholarship of the value of £100, awarded annually in June. It is open to all medical women, preferably coming from India, or going to work in India, for assistance in Post-graduate study. (o) Sarah Holborn Scholarship, value £20 a year for three or five years, awarded every alternate year; next award in 1921. (p) Dr. Margaret Todd Scholarship, tenable for four years, £37 10s. a year, awarded in alternate years; next award in July, 1921. (q) Lieutenant Edmund Lewis and Lieutenant Alan Lewis Memorial Scholarship, tenable for four years, awarded every four years; next award in July, 1924. Two Richardson-Kuhlmann Prizes are given each year, value £12, for proficiency in Clinical Obstetrics, value £8, for proficiency in senior subjects respectively. Two Evans Prizes of £2 2s. and £1 1s. are given each year on the results of the class examination in Midwifery. The Evans Prize for Operative Midwifery, value £5 5s., is awarded yearly. The Edith Pechey Phipson Prize in Pharmacology, value £3 3s., is awarded annually. There is also a small loan fund from which assistance can occasionally be given to students and to graduates who specially require pecuniary help. Prizes and Certificates of Honour are awarded in each class at the end of the session.

The Dean of the Medical School is Miss Aldrich-Blake, M.D., M.S.; the Honorary Secretary, Dr. May Thorne; and the Warden and Secretary, Miss L. M. Brooks, to whom inquiries may be addressed.

UNIVERSITY OF DURHAM.

Two Diplomas, one Licence, and six degrees are conferred—viz., the Diploma in Public Health, Diploma in Psychiatry, the Licence in Dental Surgery, and the degrees of Bachelor of Medicine, Bachelor of Surgery, Master of Surgery, Doctor of Medicine, Bachelor of Hygiene, and Doctor of Hygiene.

For the degrees of *Bachelor of Medicine* and *Bachelor of Surgery* there are four professional examinations. The subjects of the First Examination are—Elementary Anatomy, Elementary Biology, Chemistry, and Physics. The subjects of the Second Examination are—Anatomy and Physiology. The subjects for the Third Examination are—Materia Medica and Pharmacy, Pharmacology, Medical Jurisprudence, Public Health, and Pathology and Elementary Bacteriology. The subjects of the Fourth Examination are—Medicine, Clinical Medicine and Psychological Medicine, Surgery and Clinical Surgery, Operative Surgery, Midwifery and Gynaecology, Therapeutics, and Diseases of the Skin, of the Throat, Nose, and Ear, and of Children.

It is required that at least one of the five years of professional education shall be spent in attendance at the University College of Medicine, Newcastle-upon-Tyne.

For the degrees of *Doctor of Medicine* and *Master of Surgery* a candidate must not be less than 24 years of age. He must also have obtained the degrees of Bachelor of Medicine and Surgery of the University of Durham and must have been engaged for at least two years subsequently to the date of acquirement of the degree of Bachelor of Surgery, in attendance on the practice of a recognised hospital, or in the naval or military services, or in medical

or surgical practice. The candidate for the M.D. degree may present an essay or undergo an examination in the Principles and Practice of Medicine, &c. The subjects of examination for the M.S. are:—Principles and Practice of Surgery, Surgical Pathology, Surgical Anatomy, Surgical Operations, Clinical Surgery.

Doctor of Medicine (without residence).—The University of Durham has instituted a special examination whereby the degree of Doctor of Medicine may be obtained without residence. Candidates shall not be under 40 years of age and shall have been in active practice for 15 years as registered medical practitioners. They shall produce certificates of moral character from three registered members of the medical profession. The fee will be 50 guineas, of which 20 guineas will be retained if the candidate fails to satisfy the examiners.

Candidates for any of the above degrees, diplomas or licence, must give at least 28 days' notice to Professor Howden, Registrar, College of Medicine, Newcastle-upon-Tyne. In the case of the M.D. (essay) examination candidates must send in their essays before the 1st of April.

Scholarships and Prizes.—In connexion with this University the following Scholarships and prizes are awarded:—(a), (b), (c), and (d). Four Scholarships of £25 a year each, tenable for four years; the examination will be the September Matriculation Examination. Candidates must take English, Latin, Arithmetic, Euclid, Algebra, Geography, English History, and one, or two, of the three languages—French, Greek, German. (See College Calendar for special books.) Open to candidates desirous of being admitted as Medical Students. The successful candidates must take out their entire curriculum at the University of Durham College of Medicine, Newcastle-upon-Tyne. (e) Pears Scholarship of £50 a year (when vacant), tenable for three years; Matriculation Examination.—At the College of Medicine are: (f) Dickinson Scholarship, interest on £400 and gold medal; examination in Medicine, Surgery, Midwifery, and Pathology. Open to full students of the College of Medicine who have passed the third M.B. Examination. (g) Tulloch Scholarship, interest on £400; examination in Elementary Anatomy, Biology, Chemistry, and Physics. (h) Charlton Memorial Scholarship, interest on £700; examination in Medicine. Open to full students of the College entered for the class on the Principles and Practice of Medicine. (i) Gibb Scholarship, interest on £500; awarded annually as a Scholarship in Pathology to full student who passes the best examination in that subject. No student is eligible after completion of his curriculum. (j) Luke Armstrong Memorial Scholarship, interest on £680: Original Essay in Comparative Pathology. Open to all Graduates in Medicine or Hygiene and candidates for these degrees who have spent six months at the University and whose age does not exceed 30 years. (k) Stephen Scott Scholarship, interest on £1000; Original Essay on any Surgical subject. Open to any graduate in Medicine or Surgery of the University or any student of the College of Medicine. Student's age must not exceed 30 years. (l) Heath Scholarship in Surgery, of the value of £200, awarded every second year. All Graduates in Medicine or Surgery of the University are eligible. (m) Philipson Scholarships (2). The interest on £1800 to the candidates who obtain the highest marks in the Final M.B. Examinations held in March and June respectively. (n) Gibson Prize, interest on £250 stock; examination in subject of Midwifery and Diseases of Women and Children. Open to students who have attended one course of lectures on Midwifery and Gynaecology. (o) Outtersen-Wood Prize, interest on £250, in Psychological Medicine. (p) Turnbull Prize and Medal; examination in Surface Anatomy. Open to students at end of their second winter session.—At the Royal Infirmary is (q) Goyder Memorial Scholarship, interest on £325; awarded annually to student who most distinguishes himself in Clinical Medicine and Clinical Surgery at the Royal Infirmary. For further information apply to Professor R. Howden, Registrar of the College.

THE COLLEGE OF MEDICINE, Newcastle-upon-Tyne.—Clinical instruction is given at the Royal Victoria Infirmary, containing about 580 beds. In it adequate accommodation is provided for the study of the various special subjects, in addition to the ordinary clinical work. Post-graduate classes are held.

NEWCASTLE-UPON-TYNE ROYAL VICTORIA INFIRMARY.—The Infirmary was founded in 1751, but has been entirely rebuilt, the new hospital being opened by His late Majesty King Edward VII. in 1906. The number of beds is 550. The number of in-patients annually is 9500 and of out-patients 70,000. The medical students of the University of Durham attend the practice of this hospital. Clinical Lectures are delivered by the Physicians and Surgeons weekly and ward demonstrations are given daily. Tutorial classes are held by the Assistant Physicians, Assistant Surgeons, and Surgical Registrars weekly, and demonstrations are given in the several out-patient departments daily. Pathological demonstrations are given by the Pathologist daily or as opportunity occurs, and in the new buildings nothing has been spared in perfecting scientific equipment. In addition to medical and surgical in-patient and out-patient departments the following special departments are fully equipped for teaching students: Ophthalmic, Throat, Nose, and Ear, Skin, Gynaecological, and Electrical. The hospital building contains the following laboratories: 1. Special Pathological Laboratory, attached to the post-mortem rooms. 2. Bacteriological Laboratory, in which all clinical bacteriological investigations are carried out—opsonic indices estimated with a view to treatment by vaccines and serums, &c. 3. There is in addition a Clinical Laboratory attached to each ward and to the out-patient department. There are five operating theatres in use in the hospital. The surgical practice is especially good. The session opens on April 17th and Oct. 2nd of each year. Applications for detailed information should be made to the Dean, Dr. Horsley Drummond, at the hospital.

There are other institutions in addition to the Royal Victoria Infirmary at which the student of medicine of the University of Durham can receive clinical instruction. Practical Midwifery can be studied at the Newcastle Lying-in Hospital. Instruction is given in Psychological Medicine at the Sunderland Mental Hospital, Ryhope. A special course of instruction is given in the City Hospital for Infectious Diseases by the City Officer of Health. Ophthalmology is further taught at the Northumberland, Durham, and Newcastle Infirmary for Diseases of the Eye. Secretary: Mr. Richard Smith, 61, Westgate-road, Newcastle-on-Tyne.

UNIVERSITY OF BIRMINGHAM.

The University of Birmingham grants the degrees of M.B., Ch.B., M.D., Ch.M., and Ph.D. (for Research Study), and also a degree and a diploma in Public Health. The course for the Bachelors' degrees extends over five years from the date of commencement of professional study. As a rule the first four of these years must be spent in the University, but the Senate has power of recognising attendance at another University as part of the attendance qualifying for these degrees and of recognising examinations passed at such other Universities as exempting from the examinations in Chemistry, Physics, and Elementary Biology. In the case of such students at least three years must be spent in attendance upon classes at the University. The fifth year may be spent at any other medical school recognised by the University.

Degrees of Bachelor of Medicine and Bachelor of Surgery.—The student must have passed the Matriculation Examination of the Joint Board or an examination accepted in lieu thereof. All communications respecting the Matriculation Examination, and examinations accepted in lieu thereof, must be sent to the Secretary to the Board, Joint Matriculation Board, 315, Oxford-road, Manchester. First Examination.—Chemistry and Physics and Elementary Biology. Second Examination.—Anatomy and Physiology. Third Examination.—General Pathology and Bacteriology, Materia Medica, and Practical Pharmacy. Fourth Examination (at the end of the fourth year).—Forensic Medicine, Toxicology, Public Health, Therapeutics, and Special Pathology. Two years' hospital work must have been accomplished. Final Examination.—Medicine, Surgery, Midwifery, Diseases of Women, Mental Diseases, and Ophthalmology. Attendance at a general hospital for a year after the passing of the fourth examination will be required, also attendance at a fever hospital three months, maternity hospital one month, and lunatic asylum three months. Vaccination instruction must be taken out and courses of Ophthalmology, Medical and Surgical Anatomy, and Operative Surgery.

Degrees of Doctor of Medicine and Master of Surgery.—At the end of one year from the date of having passed the final M.B., Ch.B. examination the candidate will be eligible to present himself for the higher degrees of either Doctor of Medicine or Master of Surgery or both. Candidates have to present a thesis on some subject embraced in the medical curriculum, and pass a general examination in Principles and Practice of Medicine for the M.D., and one in Principles and Practice of Surgery, including operations on the cadaver for the M.Ch. A thesis of exceptional merit may exempt from any part of these examinations.

Degree of Ph.D.—The Degree of Doctor of Philosophy is conferred upon candidates who possess a medical degree of a British, Colonial, or other university approved of by the Senate of the University, and who have been engaged, to the satisfaction of the Medical Faculty, in advanced study and research for a period of not less than two years, either in a laboratory of the University or in one or more of the hospitals associated with the University. After the first year of the course candidates may carry on research elsewhere, under approved conditions, and on completing the course present an original thesis on the subject and submit themselves for oral and possibly written examination.

Fees.—Matriculation, £2; First Examination, £2; Second Examination, £2; Third Examination, £2; Fourth Examination, £2; Final Examination, £8; M.D. or Ch.M., £10.

At the University of Birmingham the following Scholarships are awarded:—(a) Myers Travelling Studentship of £150, tenable for one year, awarded by vote of committee to M.B., Ch.B. Birm., B.Sc. candidates, tenable at some University or Hospital not in Great Britain or Ireland; (b) Ingleby Scholarship of £10, awarded to the candidate at Final Examination obtaining highest "first-class" marks in the subjects of Midwifery and Diseases of Women; (c) Sydenham Scholarship of £42, tenable for three years, award of Council to orphan sons of medical practitioners; (d) Sands Cox Scholarship of £42, tenable for three years, awarded to the candidate, not being more than 19 years of age, taking the highest marks at the July Matriculation; (e) Dental Scholarship of £37 10s., Open Competitive Examination in subjects learned during apprenticeship; (f), (g), (h), and (i) Four Queen's Scholarships of £10 10s. each. In the Second and Fourth Examinations the Scholarship is awarded respectively to the student taking the first place and obtaining "first-class" marks. In the Third Examination the Scholarship is awarded to the student obtaining the highest "first-class" marks in Pathology and Bacteriology, provided that such student passes at the same examination in the subjects of *Materia Medica* and *Practical Pharmacy*. In the Final Examination the Scholarship is awarded to the candidate taking the first place in the examination—that is, obtaining the greatest aggregate number of marks—provided that in each of the subjects of Medicine, Surgery, and Midwifery he gains not less than 60 per cent. of the total available marks; (j) George Henry Marshall Scholarship of £10, awarded annually, for the encouragement of Research Work in Ophthalmology; and (k) Russell Memorial Prize, a prize of books, value about £2, awarded annually to the student who, not being of more than six years' standing as a student of the School of Medicine of the University, shall pass the best examination in the subject of Nervous Diseases.

Clinical Instruction.—The medical students of the University receive their clinical instruction by attending the amalgamated practice of the General Hospital and the Queen's Hospital, under the direction of the University Clinical Board. The hospitals possess more than 500 beds, treating annually over 8000 in-patients and 100,000 out-patients. The curriculum is adapted in the first place to the University of Birmingham, but it also meets the requirements of the examinations of other licensing bodies. At the General Hospital there are open to the students the following appointments: A surgical registrar, £200 per annum; a resident medical officer, elected annually (£155); a resident surgical officer, elected annually and eligible for re-election for three years (£180); a resident pathologist, elected for six months (£100); three house physicians and four house surgeons hold office for six months, receiving board, residence, and salaries at the rate of £100 a year; two house surgeons to the gynaecological, ophthalmic, and aural departments are elected every six months, receiving board,

residence, and a salary of £100 a year; two assistant house surgeons are elected every three months, receiving board, residence, and salaries at the rate of £40 a year; a resident medical officer at the Jaffray Hospital, who is elected annually but is eligible for re-election, and who receives £150 a year; and a resident medical assistant at this hospital, who is not necessarily qualified, is provided with board and residence, and holds office for three months. At the Queen's Hospital there are open to the student the following appointments: Three house physicians, three house surgeons, and one obstetric and ophthalmic house surgeon, who hold office for six months and have salaries at the rate of £90 a year. Thirty-eight other appointments of varying value are at the City Workhouse and Workhouse Infirmary, at the Birmingham General and Branch Dispensaries, at the Birmingham Lunatic Asylums, at the City Fever Hospitals, at the Children's Hospital, at the Birmingham and Midland Eye Hospital, at the Orthopaedic and Spinal Hospital, at the Maternity Hospital, and at the Ear and Throat Hospital.

Post-graduate Courses.—A "Lectureship in Psychotherapy" has recently been established in the University.

A course of lectures on Venereal Diseases was held during the last Winter Session for practitioners and students, and courses of Clinical Instruction in Physiology, Medicine, Children's Diseases, Radiology, and Electrical Treatment are given.

BIRMINGHAM GENERAL HOSPITAL.—374 beds are in daily use, 6440 in-patients per annum. Special wards for children, gynaecological, septic and infectious cases; special beds for eye, ear, and skin cases. About 50,000 out-patients per annum. Laboratories for bacteriology and morbid histology. Separate rooms adjoin the medical and surgical wards for clinical pathology. Five operating theatres (one for out-patients), all designed and fitted on the most modern lines. In addition to clinical teaching given in the wards and out-patient department by the honorary staff, medical and surgical tutorial classes are held for senior and junior students. Clinical instruction in all the special departments. The Jaffray Branch Hospital contains 56 beds.

QUEEN'S HOSPITAL (Beds 223).—Similar arrangements for clinical teaching are made here, and the material also is excellent. Ward and tutorial classes and post-graduate courses are regularly conducted by the staff, there are daily clinics in the out-patient department, while teaching duties are definitely assigned to the house physicians and house surgeons. There are also special departments for gynaecology and ophthalmology, radiography, bacteriology, massage, electricity, whirlpool baths, &c.

BIRMINGHAM AND MIDLAND EYE HOSPITAL, Church-street, Birmingham.—This hospital possesses 120 beds, and there is an average daily attendance of out-patients of 250. Students attending for a period of three months will be granted certificates which will qualify for the University and Conjoint Board examinations. Post-graduate courses are available on various subjects when a sufficient number of graduates are present. A limited number of Non-Resident Clinical Assistants posts are available to qualified practitioners, particulars of which can be had on application to the General Superintendent.

UNIVERSITY OF LIVERPOOL.

The degrees in the Faculty of Medicine are Bachelor of Medicine and Bachelor of Surgery (M.B. and Ch.B.), Doctor of Medicine (M.D.), Master of Surgery (Ch.M.), and Master of Hygiene (M.H.).

Degrees of Bachelor of Medicine and Bachelor of Surgery.—Candidates for the degrees of Bachelor of Medicine and of Surgery must have attained the age of 21 years on the day of graduation. At least two of the five years of medical study must have been passed in the University, and one year at least must have been passed in the University subsequently to the date of passing the First Examination. The other three years may be passed at any college or medical school recognised for this purpose by the University. Candidates must pass three examinations entitled respectively: the First Examination, the Second Examination, and the Final Examination. The fee is £5 for each examination. The subjects of the First Examination are: (1) Chemistry, Inorganic, Organic, and Physical; (2) Biology (Zoology and Botany); and (3) Physics. The examination is divided into two parts—namely, (1) Chemistry and Physics,

and (2) Biology; and candidates may present themselves in these parts separately. The subjects of the Second Examination are (a) Anatomy and Physiology (including Physiological Chemistry and Histology), and (b) *Materia Medica* and Pharmacy and Pharmacology. Candidates may present themselves in (a) or (b) separately. The subjects for the Final Examination are: (1) General Pathology, Morbid Anatomy, and Bacteriology; (2) Forensic Medicine, Toxicology, and Public Health; (3) Obstetrics and Diseases of Women; (4) Surgery, Systematic, Clinical, Operative, and Practical, including Ophthalmology; (5) Medicine, Systematic and Clinical, including Mental Diseases and Diseases of Children, and Therapeutics. The Final Examination is divided into three parts, the first consisting of subject (1), the second of subject (2), the third of subjects (3), (4), and (5). Candidates may present themselves in these parts separately. Candidates for the third part must have completed the fifth year of medical study.

Degrees of Doctor of Medicine and Master of Surgery.—No candidate will be admitted to the degree of Doctor of Medicine or Master of Surgery unless he has previously received the Degrees of Bachelor of Medicine and Bachelor of Surgery, and at least one year has elapsed since he passed the examinations for those degrees, or, in the case of the degree of Doctor, unless, having obtained substantially equivalent degrees in an approved University, he has subsequently spent two years in the University or in the Clinical School in the performance of research or the conduct of systematic clinical observations. Candidates for the degree of Doctor of Medicine are required to present a dissertation embodying the results of personal observations or original research, either in some department of medicine or of some science directly relative to medicine: provided always that original work published in scientific journals or separately shall be admissible in lieu of, or in addition to, a dissertation specially written for the degree.

The University has recently established a Diploma in Medical Radiology and Electrology—Part I., Physics; Part II., Radiology and Electrology. The parts may be taken at one examination or separately. Fees for tuition have been increased by 33½ per cent.

At this University the following Scholarships and Fellowships and Prizes are awarded:—(a) and (b) Robert Gee Entrance Scholarships, two annually, of £25 each, tenable for two years, Joint Matriculation Board Examination held in July, open to First M.B. Course Students; (c) Lyon Jones Scholarship, No. 1, of £21 per annum, tenable for two years, Competitive Examination among Junior Students in First M.B. Subjects, Perpetual Course at the University; (d) Lyon Jones Scholarship, No. 2, of £21, Competitive Examination among Senior Students in Anatomy, Physiology, Pharmacology, and *Materia Medica*; (e) Derby Exhibition of £15, Competitive Examination among Fourth- or Fifth-year Students in Clinical Subjects, and Clinical School Exhibition of £15 annually for Fourth- or Fifth-year students; (f) University Scholarship of £25 for one year, awarded on results of Second Examination for the degrees; (g) Holt Fellowships, Physiology and Pathology, of £100 each, for one year; (h) Gee Fellowship, Anatomy, of £100, for one year; (i) John Rankin Fellowships in Anatomy, two, each of the value of £120, tenable for two years; (j) Johnston Colonial Fellowship, Bio-Chemistry, of £100, for one year; (k) John W. Garrett International Fellowship, Bacteriology, of £100, for one year; (l) Thelwall Thomas Fellowship, Surgical Pathology, of £150, for one year; (m) Ethel Boyce Fellowship in Gynaecological Pathology, of £100, for one year; (n) Mary Birrell Davies Memorial Fund Scholarship, of the value of £60, tenable for four years, offered for competition in alternate years; open only to women students who will have attained the age of 19 on the first day of October next following the award; (o) Rankin Exhibition in Practical Anatomy, of £25, for one year; numerous prizes and medals.

Medical School Buildings.—Medical research has also been endowed with several new laboratories in which students can pursue research work after graduation. All the laboratories and class-rooms are situated close together, communicating with one another, and are made up of four large blocks of buildings which form one side of the College quadrangle. There are the Johnston Laboratories for Experimental Medicine and Bio-Chemistry; the Medical School for Anatomy, Surgery, Toxicology, and Ophthalmology; and the Thompson-Yates Laboratories for Physiology and Pathology. A new building for Tropical Medicine has recently been opened.

Clinical Instruction.—The Clinical School of the University now consists of four general hospitals—the ROYAL INFIRMARY, the DAVID LEWIS NORTHERN HOSPITAL, the ROYAL SOUTHERN HOSPITAL, and the STANLEY HOSPITAL; and of five special hospitals—the Eye and Ear Infirmary, the Hospital for Women, the Infirmary for Children, St. Paul's Eye Hospital, and St. George's Hospital for Skin Diseases. These hospitals contain in all a total of about 1134 beds. The organisation of these hospitals to form one teaching institution provides the medical student and the medical practitioner with a field for clinical education and study which is unrivalled in extent in the United Kingdom. All the hospitals are within easy access of the University. There are a large number of appointments to house physicianships and surgeons both at the general and special hospitals which are open to qualified students of the school.

Public Health Department.—This is located in a separate building, in which full courses of instruction are given to students for the Diplomas and Degrees of the University and of other Examining Boards.

Prospectuses and further information may be had on application to the Dean of the Faculty of Medicine, University of Liverpool.

THE VICTORIA UNIVERSITY OF MANCHESTER.

Four degrees in Medicine and Surgery are conferred by the University—viz., Bachelor of Medicine and Bachelor of Surgery (M.B. and Ch.B.), Doctor of Medicine (M.D.), and Master of Surgery (Ch.M.). A Diploma in Psychological Medicine is awarded by examination to registered medical practitioners.

Degrees of Bachelor of Medicine and Bachelor of Surgery.—Before admission to the degree of M.B. or Ch.B. candidates are required to present certificates that they will have attained the age of 21 years on the day of graduation and that they have pursued the courses of study required by the University Regulations during a period of not less than five years subsequently to the date of their registration by the General Medical Council, two of such years having been passed in the University and one year at least having been passed in the University subsequently to the date of passing the first M.B. Examination. All candidates for the degrees of Bachelor of Medicine and Bachelor of Surgery are required to satisfy the examiners in the several subjects of the following examinations. (These are now under revision.)

The First Examination.—(1) Inorganic Chemistry and Physics; (2) Biology; and (3) Elementary Organic Chemistry and Bio-Chemistry. Candidates must have attended during at least one year courses both of lectures and of laboratory work in each of the above-named subjects. The Examination is divided into three parts: Part 1, Inorganic Chemistry and Physics; Part 2, Biology; Part 3, Elementary Organic Chemistry and Bio-Chemistry; and the candidates may pass in these parts separately under certain conditions.

The Second Examination.—(1) Anatomy and Histology; (2) Physiology, including Physiological Chemistry. Candidates may pass in (1) and (2) separately under certain conditions.

The Third Examination.—(1) Pathology; (2) Pharmacology and Therapeutics. These subjects may be taken separately under certain conditions.

The Final Examination.—(1) Medicine, Systematic and Clinical (including Mental Diseases and Diseases of Children); (2) Surgery, Systematic, Clinical, and Practical; (3) Obstetrics and Gynaecology (including Clinical and Practical); (4) Forensic Medicine (including an Oral Examination); (5) Hygiene and Preventive Medicine. The Final Examination is divided into two parts.

Candidates for the Second Part of the Final Examination must have completed the fifth year of medical study.

Degree of Doctor of Medicine.—Candidates are not eligible for the degree of Doctor of Medicine unless they have previously received the degrees of Bachelor of Medicine and Bachelor of Surgery and at least one year has elapsed since they passed the examination for those degrees. Candidates may elect either (1) to present an original dissertation; or (2) to undergo an examination. The disserta-

tion must embody the results of personal observation or original research, either in some department of medicine or of some science directly relative to medicine. The examination, which will be written and practical, is in the Principles and Practice of Medicine, in Pathology, and in some other subject to be selected by the candidate.

Degree of Master of Surgery.—Candidates are not eligible for the degree of Master of Surgery unless they have previously received the degrees of Bachelor of Medicine and Bachelor of Surgery and at least one year has elapsed since they passed the examination for those degrees. The subjects of examination are as follows: (1) Surgical Anatomy; (2) Surgery; (3) Operative Surgery; (4) Clinical Surgery; (5) Ophthalmology; and (6) Pathology and Bacteriology.

Scholarships, Fellowships, and Prizes.—At this University there are 22 Foundation Scholarships, 12 Exhibitions, five being for subjects connected with medical study, a Surgical Prize, a University Fellowship (Leech Fellowship, £100), Research Fellowships in Public Health, and Honorary Research Fellowships. 13 Entrance Scholarships are tenable for Medical courses; one Scholarship is offered in Surgery, Biology, Physiology, and Diseases of Children respectively, and one General Medical and Surgical. Exhibitions are offered in Physiology and Anatomy, and one for French and German. "The Dumville" Surgical Prize is awarded on the results of the Final Examination in Surgery in the Summer Term, £15. The Leech Fellowship (£100) is for the encouragement of study and research, and is open to persons who have graduated M.B., Ch.B., in the University not more than 18 months previously. The Honorary Research Fellowships, tenable for two years, conferring the right of free use of the laboratories, are awarded generally in October on application, with evidence of capacity for independent investigation.

There are many entrance scholarships, the examinations for which are held in the month of May. Full particulars can be obtained from the Dean.

The Medical School.—This medical school, largely extended in 1895, is provided with dissecting-rooms, physiological laboratories, private laboratories, and work-rooms, besides lecture-rooms, a museum, and a library. A special laboratory is equipped for experimental work on the central nervous system. In the pathological laboratories ample provision is made for the teaching of pathology and bacteriology and for the prosecution of original research. The Helen Swindells Laboratory is specially equipped for cancer research and investigation in general pathology. Ample facilities for investigation are provided in Anatomy, Physiology, and Materia Medica. In the public health department, which is lodged in a separate institute in York Place, near the Royal Infirmary, suitable laboratory accommodation is provided for the study of sanitary chemistry, physics, and practical bacteriology in the departments of chemistry and physics and in that of pathology.

Clinical Studies.—The clinical and practical departments of medical study are taught partly in the Medical School and partly in the Royal Infirmary and St. Mary's Hospitals for Women and Children, a fever hospital, a lunatic asylum, and a convalescent home, and other special hospitals. Medical and Surgical Clinical Classes are conducted in the Infirmary, which together with the associated hospitals at Cheadle contains 1109 beds, exclusive of those reserved for military cases, and separate instruction is afforded in the elements of Medical and Surgical Physical Diagnosis, in Obstetric Medicine, Ophthalmic Surgery, and Pathological Anatomy by the different members of the staff of the Medical School and Infirmary.

Clinical Instruction.—THE MANCHESTER ROYAL INFIRMARY.—The Royal Infirmary is built on the pavilion system, near the University, and has accommodation for 628 patients. The medical side consists of five units, each unit having a testing room for the scientific investigation of morbid products and a class-room. The surgical beds are also arranged in five units, each unit having its own operation theatre, with anaesthetising, recovery, sterilising, testing, and apparatus rooms, and its own class-room attached. All of these units are occupied. The fine educational block provides very handsomely for the wants and comforts of the students, there being separate suites of rooms for the men and the women, and also a large common reading room, a lecture theatre, and a museum. The present

annual average number of in-patients is 13,650, of out-patients 27,000, and the list of casualties in the accident room has averaged 17,000 per annum. About 9000 operations are performed annually in the operation theatres. Associated with the infirmary are: (1) the Convalescent Hospital at Cheadle, containing 136 beds; (2) the Royal Lunatic Hospital at Cheadle, accommodating with its branches 430 patients; and (3) the Central Branch in the city for casualty and out-patient work, and 50 beds for pensioners. The Associated Hospitals thus contain 1244 beds and are under the same management. Women students are admitted on the same terms as men.

Fees.—Medical Practice: Three months, 7½ guineas; six months, 12 guineas; 12 months, 18 guineas; full period required by the Examining Boards, 60 guineas.

Two Entrance Scholarships in Medicine of the value of £160 each are offered annually by the Council of the Manchester University and the Medical Board of the Manchester Royal Infirmary for proficiency in Arts and Science subjects respectively. Other scholarships and prizes are mentioned in the College Syllabus. Numerous annual appointments and junior appointments may be held by those who have attended the practice of the Infirmary.

The Dean of Clinical Instruction is Dr. E. M. Brockbank.

MANCHESTER CHILDREN'S HOSPITAL, Pendlebury, Gartside-street, Manchester, and St. Anne's-on-the-Sea.—The hospital contains 190 beds and 28 in the Convalescent Home, St. Anne's-on-the-Sea. The medical staff visit the hospital daily at 10 A.M. Clinical instruction is given by the medical staff at the Hospital and Dispensary. Out-patients are seen daily at 9 A.M. at the new Out-patient Department, Gartside-street, Manchester. Secretary: Mr. W. M. Humphry.

THE MANCHESTER NORTHERN HOSPITAL FOR WOMEN AND CHILDREN, Park-place, Cheetham Hill-road, Manchester.—The hospital contains 70 beds. Out-patients are seen daily from 8.30 to 10 A.M.

UNIVERSITY OF LEEDS.

Four degrees in Medicine and Surgery are conferred—viz.: Bachelor of Medicine and Bachelor of Surgery (M.B. and Ch.B.), Doctor of Medicine (M.D.), Master of Surgery (Ch.M.), also Degrees and Diplomas in Dental Surgery and Diplomas in Public Health and in Psychological Medicine.

Degrees of Bachelor of Medicine and Bachelor of Surgery.—Candidates for these degrees are required to present certificates showing that they will have attained the age of 21 years on the day of graduation, and have attended courses approved by the University extending over not less than five years, two of such years at least having been passed in the University, one of which must be subsequent to the date of passing the First Examination. Candidates must also satisfy the examiners in the several subjects of the following examinations entitled respectively: the Matriculation Examination, or such other examination as may have been recognised by the Joint Matriculation Board in its stead; the First Examination; the Second Examination; and the Final Examination.

The First Examination.—The First Examination consists of: Part I., Physics and Chemistry; Part II., Biology. Candidates will be allowed to pass the two parts separately.

The Second Examination.—The Second Examination consists of: Part I., Anatomy and Physiology; Part II., Materia Medica and Pharmacy. Candidates will be allowed to pass the two parts separately.

The Final Examination.—The Final Examination consists of: Part I., Pathology and Bacteriology. Part II., Forensic Medicine and Public Health. Part III., Medicine: Systematic and Clinical, including Mental Diseases and Diseases of Children; Surgery—Systematic, Clinical, and Practical; Obstetrics, and Gynaecology—Systematic, Clinical, and Practical; Pharmacology and Therapeutics. Candidates will be allowed to pass Parts II. and III. separately or together, and they may present themselves for examination in Part I. at the end of the tenth term.

Degree of Doctor of Medicine.—Candidates are not eligible for the degree of Doctor of Medicine or Master of Surgery unless they have previously received the degrees of Bachelor of Medicine and Bachelor of Surgery of the University (or of Victoria prior to December, 1904) and at least one year has elapsed since they passed the examination for those

degrees. Candidates for the degree of Doctor of Medicine are required to present a dissertation and, if the dissertation be accepted, may be required to pass an examination.

The first term commences on Oct. 1st. Prospectus, &c., can be obtained from the Dean of the Medical School.

Post-graduate work.—Practitioners wishing to attend Infirmary practice during short periods may do so on terms which may be obtained from the Clinical Sub-Dean.

Clinical Instruction.—THE LEEDS GENERAL INFIRMARY, in connexion with this medical faculty, has accommodation for 620 in-patients, including 88 beds at branch hospitals in the country. During the last year 9495 in-patients and 37,746 new out-patients were treated. Clinical teaching takes place daily in the wards, and Clinical lectures are given in Medicine and Surgery by the Physicians and Surgeons. There are Medical, Surgical, Ophthalmic, Aural, Electro-therapeutic, and Radiographic Departments, in each of which special instruction is imparted to students. A Gynaecological and Extern Obstetric Department, together with Laryngeal and Skin Clinics, are in operation. Several valuable prizes are given at the end of each session. Numerous appointments at the Infirmary are annually open to students after qualification.

UNIVERSITY OF SHEFFIELD.

The Degrees in the Faculty of Medicine are Bachelor of Medicine and Bachelor of Surgery (M.B., Ch.B.), Doctor of Medicine (M.D.), and Master of Surgery (Ch.M.). The courses and degrees in the Faculty of Medicine are open to men and women alike. Candidates must matriculate in the University or pass such other examination as may be recognised for this purpose by the University and sanctioned by the Joint Matriculation Board.

Degrees of Bachelor of Medicine and Bachelor of Surgery.—A candidate must have attained the age of 21 years on the day of graduation and pursue the courses of study required by the University regulations during a period of not less than five years subsequently to the date of his matriculation, three of such years at least having been passed in the University, one at least being subsequent to the passing of the First Examination.

The First Examination.—The subjects of the examination are Chemistry, Physics, and Biology. The Intermediate B.Sc. Examination in these subjects will, on payment of the required additional fee, be accepted instead of this examination. Candidates must, after matriculation and registration as medical students, have attended courses of instruction (lectures and laboratory work) in chemistry, physics, and biology for one year each.

The Second Examination.—The subjects of the examination are Anatomy and Physiology.

The Third Examination.—The subjects of the examination are Pathology and Pharmacology. A candidate entering for the first, second, or third examination, who shall pass creditably in one subject of either examination and obtain a certain minimum of marks in the other, may enter for such other subject separately in a subsequent examination. Candidates must have completed the fourth year of professional study.

The Final Examination.—The subjects of the examination are Medicine (including Forensic Medicine, Public Health, Mental Diseases, and Diseases of Children); Surgery; and Obstetrics (including Gynaecology). Candidates must satisfy the examiners in all subjects at the same examination. Candidates must have completed the fifth year of professional study.

Degree of Doctor of Medicine.—Candidates for the degree of Doctor of Medicine must have passed the examination for the degrees of M.B., Ch.B. at least one year previously, must present a thesis embodying observations in some subject approved by the professor of medicine, and must pass an examination in the Principles and Practice of Medicine.

Degree of Master of Surgery.—Candidates must have taken the M.B., Ch.B. at least one year previously, and must since have held for not less than six months a surgical appointment in a public hospital. The subjects of examination are Systematic, Clinical, and Operative Surgery, Surgical Anatomy, Surgical Pathology, and Bacteriology.

Scholarships, &c.—At this University, in addition to four Edgar Allen scholarships of £100 a year for three years,

holders of which can take the courses in the Faculty of Medicine, there are 8 scholarships and a Town Trust Fellowship. Full particulars as to curriculum, scholarships, &c., may be had on application to the Registrar or to the Dean of the Medical Faculty.

The Medical School.—The new buildings of the University opened in 1905 are situated at the west end of the city, adjoining Weston Park, and the Medical Department occupies the entire north wing of the University quadrangle. The various athletic and other students' societies are under the management of a Students' Representative Council, elected annually. There are large and comfortable common rooms both for men and women students. A refectory is open daily at the University where students may obtain refreshments, lunch, dinner, &c., at extremely moderate prices. The University journal, *Flourensianus*, edited by a committee of staff and students, is published each term. The University Hostel, "Oakholme," Clarkehouse-road, is recognised by the Senate as a residence for women students, full particulars of which may be obtained of the tutor for women students.

Clinical Instruction.—The University is within easy reach of the various hospitals with which it is connected for clinical purposes. These are as follows: The ROYAL INFIRMARY (Secretary, Mr. J. W. Barnes), containing 326 beds, with an annual average number of over 3800 in-patients, over 11,500 out-patients, and over 23,000 casualties; the Royal Hospital (Hon. Sec., *pro tem.*, to the medical and surgical staff, Mr. Vincent Townrow), with 191 beds, and an annual number of 3000 in-patients, over 20,000 out-patients, and nearly 20,000 casualties; and the Jessop Hospital for Diseases of Women, with 80 beds, about 900 in-patients, and about 3057 out-patients; also a Maternity department, with about 450 in-patients per annum and about 700 out-patient cases attended. Special courses on Fevers are held at the City Fever Hospitals (600 beds) and on Mental Diseases at the South Yorkshire Asylum (1610 beds). For purposes of clinical practice the practices of the Royal Infirmary and Royal Hospital are amalgamated, giving a total of 511 beds for the treatment of medical, surgical, and special cases. There are special departments for the treatment of Diseases of the Eye at each institution, with wards assigned to them. In addition to these the Royal Infirmary has special departments for the treatment of Diseases of the Skin and Ear, with beds assigned to them, whilst at the Royal Hospital there are special out-patient departments for Diseases of the Throat, Ear, Skin, Orthopaedics, and Mental Diseases. Instruction is also given at the South Yorkshire Asylum (1694 beds). During the last year over 6000 patients passed through the wards of the two institutions, while those attending as out-patients numbered over 45,000. The department of Pathology and Bacteriology in the University is fitted with every requirement for the most advanced work in these subjects.

Fees.—The Composition Fee is £30 a year for each of the five years.

UNIVERSITY OF BRISTOL.

In the Faculty of Medicine there are the following degrees:—Bachelor of Medicine and Bachelor of Surgery (M.B. and Ch.B.), Doctor of Medicine (M.D.), Master of Surgery (Ch.M.), Bachelor of Dental Surgery (B.D.S.), and Master of Dental Surgery (M.D.S.). There are also the following diplomas: Diploma in Public Health (D.P.H.), Diploma in Dental Surgery (L.D.S.), and Diploma in Veterinary State Medicine.

All candidates for degrees in Medicine, Surgery, and Dentistry are required to pass an examination called the School Certificate Examination, or to pass such examination as may be regarded as equivalent by the Senate. All courses, degrees, and diplomas are open to men and women alike. The winter session commences on Oct. 1st, 1920.

Conjoined Degrees of Bachelor of Medicine and Bachelor of Surgery.—Candidates shall be not less than 21 years of age and shall have pursued the courses prescribed by University Regulations during not less than five and a half years, of which three shall have been passed in the University, and two of these three subsequent to pass in the second examination. All candidates for the degrees of M.B., Ch.B., are required to satisfy the examiners in the several subjects of three examinations.

The First Examination.—The subjects of examination are: Chemistry (Inorganic), Physics, and Biology, the courses

pursued being those for the time being approved for the intermediate part of the B.Sc. curriculum. This part of the curriculum shall extend over one year. (Candidates who have passed the Higher School Certificate approved by the Board of Education in these subjects will not be required to sit for the first examination and will be regarded as having completed one year of study.)

The Second Examination.—The subjects of examination are: Organic Chemistry and Elementary Anatomy (Part I.) and Advanced Anatomy and Physiology (Part II.). Parts I. and II. may be passed separately or together.

The Final Examination.—The subjects of examination are: Materia Medica and Pharmacy, Pharmacology and Therapeutics, General Pathology, Morbid Anatomy, and Bacteriology (Part I.); Special Pathology, Forensic Medicine, Toxicology, and Public Health, Obstetrics (including Diseases of Women), Surgery (Systematic, Clinical, Practical, and Operative), Medicine (Systematic, Clinical, and Practical, including Mental Diseases) (Part II.). Candidates may pass I. and II. together, or separately, and Forensic Medicine and Toxicology may, at the option of the candidate, be taken either with Part I. or Part II.

Degree of Doctor of Medicine.—Candidates shall be Bachelors of the University of not less than two years' standing as such and may elect either (1) to pass an examination in General Medicine, or (2) to pass an examination in State Medicine, or (3) to present a Dissertation. The candidate who elects to pass the examination in State Medicine must hold a diploma in Public Health of some University or College, and the candidate who elects to present a Dissertation may be examined in the subject thereof.

Degree of Master of Surgery.—Candidates shall be Bachelors of not less than two years as such, during which period they shall have attended the Surgical Practice of an institution approved for the purpose. They shall pass an examination in Surgical Anatomy, Pathology, and Bacteriology, and Operative, Clinical, and General Surgery, and present to the University a Dissertation on some subject of Surgery.

Clinical Instruction.—The allied hospitals (BRISTOL ROYAL INFIRMARY and BRISTOL GENERAL HOSPITAL) have between them about 600 beds and extensive out-patient departments, special clinics for Diseases of Women and Children and those of the Eye, Throat, and Ear, in addition to large and well-equipped departments for Dental work and large outdoor Maternity Departments.

At each of these institutions there are well-arranged pathological museums, post-mortem rooms, and laboratories for Morbid Anatomy. There are also laboratories for work in Clinical Pathology, Bacteriology, and Cytology, in which special instruction is given in these subjects. Departments are provided and well-equipped for X ray work, both for diagnosis and treatment, the various forms of Electrical treatment, including High Frequency Currents, Electric Baths, Finsen Light treatment, and Massage.

The students of the school also attend the practice of the Royal Hospital for Sick Children and Women, containing 140 beds, and that of the Bristol Eye Hospital, with 40 beds. The total number of beds available for clinical instruction is therefore about 750.

Daily Post-Graduate Study.—For those who are able to devote several hours each day to hospital practice the University offers special facilities for Post-graduate work. Qualified medical practitioners may be appointed as Clinical Assistants for a period of one or more months. They may act as Assistants, if times permit, in more than one department and in any of the hospitals during their period of study. They will be entitled to the use of the clinical laboratories and medical library, and have the right to attend in all departments, including operations, post-graduate and ordinary clinical demonstrations, and post-mortem examinations. Fee, £3 3s. per month.

Post-Graduate Clinical Work.—Demonstration courses with weekly lectures are held during May, June, and July. Fee, £2 2s. All inquiries and applications for admission should be addressed to the Director of Post-graduate Studies (Clinical Section), Pathological Department, University of Bristol, who can be seen on any day by appointment at the Pathological Department.

Further information as to scholarships, curricula, and fees can be obtained from the Dean of the Faculty of Medicine or the Registrar of the University.

UNIVERSITY OF WALES.

This University has the privilege of granting degrees in Medicine and Diplomas in Public Health. At the three constituent Colleges of Aberystwyth, Bangor, and Cardiff there are Professors of Chemistry, Botany, Zoology, and Physics, so that the students of the University can obtain proper instruction in the ancillary subjects. The foundation of a Medical Faculty has been laid at University College, Cardiff, where there is a recognised school of medicine.

University College, Cardiff: School of Medicine.—All classes are open to both men and women students. The courses of instruction given in the School of Medicine at the University College, Cardiff, are recognised as qualifying for the examinations of the Universities, Royal Colleges, and other licensing bodies in Great Britain and Ireland, and they are specially adapted to meet the needs of those University students studying for Welsh and London degrees. Having spent two or three years in study at Cardiff, and having passed the corresponding examinations, a student may proceed to London or elsewhere and complete his qualifying course for a University degree or for a diploma. It will be possible when the Welsh National School of Medicine is fully constituted for students to pursue the complete curriculum at Cardiff. Students who are preparing for these examinations may compound for their courses by paying a fee of £63, while a composition fee of £41 10s. includes all the necessary courses for the first and second examinations for the Diploma of the Conjoint Board. In all cases the composition fees may be paid by instalments. Hospital instruction is given at the King Edward VII.'s Hospital, Cardiff. The attention of students about to matriculate is drawn to the numerous entrance scholarships offered for competition at University College, Cardiff, in April next, most of which may be held by medical students. Full particulars of the examination for these may be obtained by application to the Registrar. In the department of Public Health established in 1899 instruction is given qualifying for the D.P.H. examinations. A course for the training of Health Visitors has been instituted. Further information may be obtained from the Dean of the Faculty of Medicine.

Clinical Instruction.—KING EDWARD VII.'S HOSPITAL, CARDIFF.—Students can attend the practice of this Hospital, which contains 450 beds. Founded 1837.—SWANSEA GENERAL AND EYE HOSPITAL.—Hospital, 256 beds, 186 civilian, 70 (sailor and soldier pensioners), Convalescent Home, 27 beds. In-patients, 3322; out-patients, 10,144. The accommodation is about to be increased by 50 beds. There is a full-time paid Pathologist and paid Assistant Pathologist, with a completely fitted Laboratory, and also a Venereal Diseases Department.

ENGLISH MEDICAL CORPORATIONS GRANTING DIPLOMAS.

EXAMINING BOARD IN ENGLAND BY THE ROYAL COLLEGE OF PHYSICIANS OF LONDON AND THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

Under this heading we give the regulations for the examinations enjoined by the Conjoint Examining Board of the Royal Colleges of Physicians of London and Surgeons of England and of the Society of Apothecaries upon students desiring their respective diplomas of qualification. We do not give any list of schools recognised by these bodies as eligible to prepare students for their examinations beyond mentioning that all the schools which we have already described (under the heading of the Universities to which they are attached) are recognised as suitable places of instruction by the corporations granting medical diplomas. The courses of study at the principal colonial medical schools are also recognised as qualifying for the examinations of these corporations.

Professional Examinations.—There are three Examinations, called herein the First Examination, the Second Examination, and the Third or Final Examination, each being partly written, partly oral, and partly practical. These examinations will be held in the months of January, April, July, and September or October

unless otherwise appointed. Every candidate must give notice in writing to Mr. F. G. Hallett, O.B.E., Secretary of the Examining Board, Examination Hall, Queen-square, Bloomsbury, W.C., 14 clear days before the day of the examination, transmitting at the same time the required certificates.

The subjects of the *First Examination* are—Chemistry, Physics, and Elementary Biology. A candidate may take this examination in two parts at different times (Chemistry and Physics must be taken together until the required standard is reached in both or in one of these subjects, but a candidate will not be allowed to pass in one without obtaining at the same time at least half the number of marks required to pass in the other). A candidate will be admitted to examination in Chemistry and Physics, and in Elementary Biology on producing evidence of having passed the required Preliminary Examination and of having received instruction in these subjects at a recognised institution. A candidate rejected in one part or more of the First Examination will not be admitted to re-examination until after the lapse of a period of not less than three months from the date of rejection, and he will be re-examined in the subject or subjects in which he has been rejected. If referred in Chemistry, Physics, or Biology he must produce evidence of further instruction at a recognised institution. Any candidate who shall produce satisfactory evidence of having passed an examination for a degree in Medicine in any of the subjects of this examination conducted at a university in the United Kingdom, in India, or in a British colony will be exempt from examination in those subjects.

The fees for admission to the *First Examination* are as follows: For the whole examination, First Admission, £10 10s.; re-examination in Chemistry, £3 3s.; re-examination in Physics, £2 2s.; re-examination in Biology, £2 2s. Second Conjoint: This examination is in two parts—viz.: Part I., Anatomy and Physiology; Part II., Materia Medica and Pharmacology. A candidate must have attended at a recognised medical school, lectures on Anatomy, Physiology, and a course of Practical Physiology and Histology, and have dissected for twelve months during the ordinary sessions. He must also attend three months' lectures or demonstrations in Pharmacology and receive instruction in Practical Pharmacy. Part II. may be passed at the same time as Part I., or before or after that part, provided the conditions of admission to the whole examination have been fulfilled. The study of Anatomy and Physiology before passing in two of the three subjects of the first examination is not recognised. If rejected, a candidate before being admitted to re-examination must continue his studies at a recognised medical school for not less than three months.

Second Examination: £10 10s.; re-examination in Part I., £6 6s.; re-examination in Part II., £3 3s.

The subjects of the *Third or Final Examination* are: Part I., Medicine, including Medical Anatomy, Pathology, Therapeutics, Forensic Medicine, and Public Health. Part II., Surgery, including Pathology, Surgical Anatomy, and the use of Surgical Appliances. Part III., Midwifery and Diseases Peculiar to Women. Candidates may present themselves for Parts I., II., and III. of the examination separately or together at the expiration of not less than two years (24 months) from the date of passing the Second Examination on production of the certificates of study required for the respective parts, provided that the examination is not completed before the expiration of five years from the date of passing the Preliminary Examination.

The fees for admission to the *Third or Final Examination* are as follows: Third Examination: £21; re-examination in Part I., Medicine, £6 6s.; Part II., Surgery, £6 6s.; Part III., Midwifery and Diseases of Women, £4 4s. Members of English, Scotch, or Irish Universities £5 5s. for first admission to the examination and £36 15s. for the diplomas.

A candidate referred on the *Third or Final Examination* will not be admitted to re-examination until after the lapse of a period of not less than three months from the date of rejection and will be required, before being admitted to re-examination, to produce a certificate, in regard to Medicine and Surgery, of having attended the Medical and Surgical Practice, or the Medical or Surgical Practice, as the case may be, during the period of his reference; and in regard to Midwifery and Diseases Peculiar to Women a certificate of having received,

subsequently to the date of his reference, not less than three months' instruction in that subject by a recognised teacher.

Students of recognised universities in England, Scotland, and Ireland, who have passed examinations for a degree in Medicine at their universities in the subjects of the First and Second Examinations of the Examining Board, may enter for the Final Examination at the expiration of two years from the date of passing in Anatomy and Physiology on production of the required certificates.

Members of certain recognised Indian, Colonial, and Foreign universities who have passed examinations for the Degree of Doctor or Bachelor of Medicine or Surgery in the subjects of the First and Second Examinations of the Examining Board may present themselves for the Final Examination under special conditions. The Board also grants Diplomas in Psychological Medicine and in Ophthalmic Medicine and Surgery. Candidates must hold a Medical qualification registrable in the United Kingdom or be Graduates in Medicine of an Indian, Colonial, or Foreign University. Particulars and conditions of admission to all examinations, fees, &c., may be obtained from the Secretary of the Examining Board, Examination Hall, Queen-square, Bloomsbury, London, W.C. 1.

ROYAL COLLEGE OF PHYSICIANS OF LONDON: THE MEMBERSHIP AND FELLOWSHIP.

The College confers two separate diplomas—the *Fellowship*, a purely honorary distinction, and the *Membership*, obtained by examination.

Membership.—Every candidate must have attained the age of 25 years, and be already registered or have passed a qualifying examination in accordance with the Medical Act of 1886, or obtained the degree of Doctor or Bachelor of Medicine at a University in the United Kingdom, in India, or a British colony, or a foreign qualification, for which the courses of study and the examinations have been adjudged by the Censors' Board to be satisfactory. The nature and extent of this examination will, in the case of each candidate, be determined by the Censors' Board. All other candidates must produce proof of having passed the examinations required for the Licence of the College. The examination is directed partly to pathology and partly to the practice of medicine and may be modified in circumstances to be ascertained by application to the Registrar. The fee for admission as a Member of the College is 40 guineas, except when the candidate for Membership is a Licentiate of the College, in which case the fee already paid for the Licence shall be deducted from the 40 guineas. The fee for the examination is £6 6s.

Fellowship.—The *Fellows* are selected annually from the ranks of the *Members* by the Comitia of the College.

ROYAL COLLEGE OF SURGEONS OF ENGLAND: THE FELLOWSHIP.

The Royal College of Surgeons of England confers its diploma of Fellow upon a few distinguished persons in an honorary capacity. Two Members of long standing may also be elected to the Fellowship annually. But the bulk of the Fellows obtain the diploma as the result of examination.

Fellowship.—The examination for the Fellowship is divided into two parts—viz., the First Examination and the Second Examination. The subjects of the First Examination are Anatomy and Physiology, and those of the Second Examination are Surgery, including Surgical Anatomy and Pathology. The examinations are partly written and partly *viva voce* and include the examination of patients and the performance of operations on the dead body. The examinations are held in May and November.

The fees for examination are:—First Examination, first admission 8 guineas, and for each readmission 5 guineas. Second Examination, each admission, 12 guineas. Of such examination fees 20 guineas will be reckoned as part of the fee payable upon admission to the Fellowship. The fee to be paid upon admission to the Fellowship is 30 guineas, except when the candidate is a Member of the College, in which case the fee is 20 guineas.

A Member of the College is admissible to the First Examination at any time after receiving his Diploma of Member-

ship. A candidate who is not a Member is admissible after passing the First and Second Examinations of the English Conjoint Board, or the equivalent examinations in his University, on the production of certificates of attendance upon certain prescribed courses.

A Member of the College is admissible to the Second Examination at any time after having passed the First Examination, on producing satisfactory evidence of having been engaged not less than six years in the study (or study and practice) of the profession.

A candidate who is not a Member of the College must possess the registrable surgical and medical degrees of universities recognised by the Council and must have been engaged in the study (or study and practice) of the profession for not less than four years subsequent to the date of obtaining the recognised qualification, one year of which shall have been spent in attendance on the Surgical Practice of a recognised hospital. The diploma of Fellow is not conferred upon successful candidates until they have attained the age of 25 years.

The Regulations may be obtained on application to the Director of Examinations, Examination Hall, Queen-square, Bloomsbury, London, W.C. 1.

SOCIETY OF APOTHECARIES OF LONDON.

The Primary examination is held quarterly in two parts. Part I. Elementary Biology; Chemistry, Chemical Physics; Practical Chemistry; and Materia Medica and Pharmacy. Part II. includes Anatomy, Physiology, and Histology. This examination cannot be passed before the completion of twelve months' Practical Anatomy with Demonstrations, and these subjects cannot be taken separately except in the event of the candidate having previously passed in one.

The Final examination is held monthly except in September. It is in two sections. Section I. consists of three parts. Part I. Principles and Practice of Surgery, Surgical Pathology, and Surgical Anatomy, Operative Manipulation, Instruments, and Appliances. Part II. Medicine, Pharmacology, Pathology, and Morbid Histology; Forensic Medicine, Hygiene, Theory and Practice of Vaccination; and Mental Diseases. Part III. includes Midwifery, Gynaecology, and Diseases of New-born Children and the Use of Obstetric Instruments and Appliances. Section II. of the Final examination consists of two Parts. Part I. Clinical Surgery; Part II. Clinical Medicine and Medical Anatomy.

The course of study for the *Final examination, Section I.*, includes attendance on the Surgical and Medical Practice, with Post-mortem Examinations, at a hospital connected with a medical school for a period of two winter and two summer sessions, including a course of Practical Midwifery, with attendance on 20 Midwifery cases. The course of medical study must extend over 45 months, and the offices of dresser or clinical clerk must be held at a hospital or other institution recognised by the Society. Two years must elapse after a candidate has passed the examination in Anatomy and Physiology before sitting for any part of the Final examination.

The course of study for the *Final examination, Section II.*, includes either attendance on the Practice of Medicine and Surgery at a hospital or other institution recognised by the Society for a further period of 12 months, or six months as above and six months as a pupil of a registered practitioner holding a public medical or surgical appointment, or attendance at two special hospitals for six months (three months at each hospital), and for six months at a general hospital, all such hospitals to be recognised by the Society. Evidence shall also be given of practical instruction in Infectious Diseases and in Mental Diseases (at a lunatic asylum or in the wards of an institution containing a special ward set apart for the treatment of mental diseases), and in any two of the following subjects: Ophthalmic Surgery, Laryngology with Rhinology and Otology, Dermatology, and Diseases of Children. Candidates intending to present themselves for examination are required to give 14 days' notice. The fee for the Licence is 20 guineas. Female candidates are admitted to examinations. The examination offices are open from 10 A.M. to 4 P.M.: on Saturdays from 10 A.M. to 1 P.M. All letters should be addressed to the Secretary, Court of Examiners, Society of Apothecaries of London, Blackfriars, E.C. 4.

METROPOLITAN ANCILLARY SCHOOLS AND HOSPITALS AFFORDING FACILITIES FOR CLINICAL OBSERVATION.

The institutions which follow provide to the medical student and medical graduate facilities for different forms of instruction and clinical observation. In each case further information can be obtained from the secretary of the hospital.

THE SEAMEN'S HOSPITAL SOCIETY possesses three hospitals—the *Dreadnought* Hospital at Greenwich, 250 beds, and the Branch Hospital in the Royal Victoria and Albert Docks, E., 50 beds; the Hospital for Tropical Diseases, Endsleigh-gardens, London, N.W. 1; and the Angas Home 30 beds. It has also two Dispensaries—one in the East India Dock-road and the other at Gravesend—from which the patients are transferred to the hospitals. Secretary: Mr. P. J. Michelli, C.M.G.

WEST LONDON HOSPITAL, Hammersmith, W. 6.—This hospital has 160 beds, all of which are constantly in use. 2074 in-patients and 32,631 out-patients, whose attendances numbered 174,625, were treated last year. Attached to the hospital is the West London Post-Graduate College. The practice of the hospital is reserved exclusively for qualified men, no junior students being admitted. Instruction is given in the medical and surgical out-patient rooms and demonstrations are given in the wards every morning and afternoon. Lectures and demonstrations are given daily. Special Classes are held in Diseases of the Throat and Nose, Skin, and Eye, and in Gynaecology, Medical Electricity, Operative Surgery, Bacteriology, Anaesthetics, Intestinal Surgery, Medical and Surgical Diseases of Children, Blood and Urine, Clinical Microscopy, Tropical Medicine, Cystoscopy, Venereal Diseases, and Operative Ophthalmology. The accommodation for post-graduates consists of a large lecture room, together with reading, writing, and class rooms, &c. The hospital has a fully equipped pathological laboratory at which instruction is given in elementary bacteriology, a class being held every month. The fees for hospital practice, including lectures, are £6 6s. for three months, or £15 15s. for one year. The certificate of the hospital is accepted by the Admiralty, War Office, Colonial Office, and India Office in cases of study leave. Further information can be obtained on application to the Deans, Dr. Arthur Saunders and Mr. Bishop Harman, at the Hospital. Secretary of the Hospital: Mr. H. A. Madge.

GREAT NORTHERN CENTRAL HOSPITAL, Holloway-road, N. 7.—This hospital is recognised by the Examining Board in England of the Royal Colleges of Physicians and Surgeons as a place of study during the fifth year of the medical curriculum. Besides the Honorary Staff there are six Anaesthetists, Pathologist, Resident Medical Officer, one resident House Physician, three resident House Surgeons, and resident casualty officer. The hospital contains 230 beds, which are fully occupied. There is also a ward for children under five years of age. The large rectangular and circular wards, each of which contains 35 beds, the observation wards, the two operation theatres, general and special out-patient and pathological departments, are specially designed with a view of offering the greatest facilities for clinical work. There is also a well-appointed electro-therapeutic department. The Pathological Department has been extended and is under the control of a Director of Clinical Pathology. The Reckitt Convalescent Home at Clacton-on-Sea belongs to the hospital. It contains 30 beds. Special departments have also been established for the treatment of tuberculosis and venereal diseases. A Hospital of Recovery containing 60 beds has now been established at "Summerlee," East Finchley, which is placed at the disposal of discharged soldiers and sailors as well as civilians. Medical practitioners are cordially invited to see the general and special practice of the hospital. Demonstrations are given daily in the wards and out-patient departments. Clinical assistants (qualified), clinical clerks, and pathological clerks are appointed in the general and special departments and may receive certificates at the end of their terms of office.

Further particulars from the Secretary of the Medical Committee at the Hospital.

PRINCE OF WALES'S GENERAL HOSPITAL, Tottenham, N.—This general hospital is in the midst of a densely populated neighbourhood of more than half a million inhabitants. It contains medical, surgical, gynaecological, and children's wards, having 125 beds. There are special departments for gynaecological cases, diseases of the eye, ear, throat, and nose, skin diseases, plastic surgery, medical electricity, radiography, and dentistry. Operations are performed every afternoon of the week (except Saturday) at 2.30 P.M. Clinical instruction, ordinarily including laboratory classes, and lectures are given in the wards and out-patient departments, laboratories, and lecture hall in connexion with the North-East London Post-Graduate College attached. There are four Resident Medical Officers, and Clinical Assistants are appointed under certain conditions. Further particulars in regard to the hospital may be obtained from Mr. H. W. Carson, Secretary to the Medical Committee, 111, Harley-street, W.; or from Dr. A. J. Whiting, Dean of the North-East London Post-Graduate College, 19A, Cavendish-square, W. Secretary: Mr. F. W. Drewett.

LONDON TEMPERANCE HOSPITAL, Hampstead-road, N.W. (Established 1873; Incorporated 1917).—The hospital contains 120 beds. The in-patients in 1919 were 1223, and the out-patients and casualties numbered 16,466 new cases. The medical and surgical practice of the hospital is open to students and practitioners. Operations: Mondays at 2 P.M., Tuesdays, Wednesdays, Thursdays, and Fridays at 9 A.M.

HAMPSTEAD GENERAL AND NORTH-WEST LONDON HOSPITAL.—The Hampstead General Hospital (Haverstock Hill) and the North-West London Hospital (formerly at Kentish Town) have been amalgamated since 1907. The Hampstead General Hospital (128 beds—viz., 102 free, 6 isolation, &c., and 20 paying or contributory) accommodates the in-patients from the districts hitherto served by both hospitals. The out-patients, with the exception of Hampstead casualty and emergency cases, attend exclusively at the Out-patients Department, Bayham-street, Camden Town. Further particulars from the secretary at the hospital (Haverstock Hill, N.W. 3).

ELIZABETH GARRETT ANDERSON HOSPITAL, 144, Euston-road, N.W.—A number of the students of the London School of Medicine for Women work in the E.G.A. Hospital under the visiting staff, and in return for much valued clinical gynaecological teaching they perform the duties assigned to students in the wards of a general hospital. Post-graduate courses in the treatment of venereal disease are held in conjunction with the London School of Medicine for Women. Secretary: Miss Imogen H. Murphy.

THE SOUTH LONDON HOSPITAL FOR WOMEN, South Side, Clapham Common, S.W.; Out-patient Department: 86-90, Newington Causeway, S.E.—This hospital, officered entirely by medical women, is a general hospital for women, girls, and small children of both sexes, and provides accommodation for 80 patients. All diseases are treated with the exception of acute infectious fevers and mental disease. There are Ophthalmic, X Ray, and Pathological Departments. The hospital is a centre for the treatment of venereal diseases under the Public Health (Venereal Diseases) Regulations, 1916. The provision of additional facilities for post-graduate training for medical women is one of the special objects of the hospital. The number of in-patients treated during the year 1919 was 1142. At the Out-patient Department in Newington Causeway 6942 new cases were treated during the past year, the total number of out-patient attendances amounting to 33,015. Clinical assistants (qualified women only) are from time to time appointed in the Out-patient Department. Secretary: Miss M. E. Ridler.

FRENCH HOSPITAL AND DISPENSARY, Shaftesbury-avenue, W.C.—This hospital, which was founded in 1867 to afford medical treatment for poor foreigners who speak the French language, has 74 beds. The Convalescent Home and Retreat for Aged French People at Brighton contains 61 beds. Secretary: Mr. G. Pondepeyre.

ITALIAN HOSPITAL, Queen-square, W.C.—This institution was established in 1884 for the maintenance and medical treatment of Italian and Italian-speaking people, irrespective of their religious and political

opinions, who may be suffering from sickness or bodily infirmity, but the sick poor of any nationality are also admitted for treatment. The institution also provides surgical and medical relief to Italians and others not being inmates of the hospital. It has 50 beds.

GERMAN HOSPITAL, Dalston, E. 8.—This hospital was founded in 1845 with the object of supplying medical aid to poor people speaking the German language and for cases of emergency and of accident. It has 124 beds, including a sanatorium with 10 beds. Also a convalescent home at Hitchin with 40 beds, occupied, since 1915, by convalescent British soldiers.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC (Albany Memorial), Queen-square, Bloomsbury, W.C.—The hospital, with the Finchley branch, and branches in Bloomsbury and Clapham Park, contains 270 beds and cots. The physicians attend every Monday, Tuesday, Thursday, and Friday at 2 P.M. In- and out-patient practice at that hour. Clinical Clerks are appointed under the in-patient and out-patient physicians. Lectures are given on Tuesdays and Fridays at 3.30. The hospital has been recognised by the Conjoint Board for England as a place where part of the fifth year may be devoted to clinical work. All communications concerning clinical appointments, lectures, hospital practice, and fees should be addressed to the Secretary at the hospital.

HOSPITAL FOR EPILEPSY AND PARALYSIS, &c., Maida Vale, W. (85 beds).—Both in-patient and out-patient departments of this hospital are open free to students as well as to medical graduates. Secretary and General Superintendent: Mr. H. W. Burleigh.

WEST-END HOSPITAL FOR DISEASES OF THE NERVOUS SYSTEM, PARALYSIS, AND EPILEPSY, 73, Welbeck-street, W.—Graduates in medicine and senior students may attend demonstrations in the Out-patient Department. No fees are charged. The Savill Prize and Medal are at present in abeyance, as well as routine demonstrations by the staff.

BETHLEM ROYAL HOSPITAL, St. George's-road, S.E.—This hospital is open for the admission of two Resident House Physicians who have recently obtained their diplomas to practise Medicine and Surgery. They are permitted to reside in the hospital for a term generally not exceeding six months, commencing May 1st and Nov. 1st, and are provided with apartments, complete board, attendance, laundry, and a salary at the rate of £100 per annum. They are under the direction of the Physician Superintendent and are elected by the Committee from candidates whose testimonials appear to be most satisfactory. The students of certain specified London Medical Schools receive Clinical Instruction in the wards of the hospital and qualified practitioners and other students may attend for a period of three months on payment of a fee. A department for nervous diseases has been instituted in a building quite apart from the main hospital. Neurological and early mental cases are dealt with.

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Brompton.—The hospital contains 333 beds. The Sanatorium at Frimley contains 100 beds and 50 beds for paying patients. Six House Physicians reside in the hospital for a term of six months; their duties include attendance in the out-patient department. Pupils are admitted to the practice of the hospital: terms £2 2s. for one month; three months, £4 4s.; six months, £7 7s. Clinical Demonstrations are given throughout the year by members of the medical staff. Clinical Assistants are appointed to the Assistant Physicians in the out-patient department and Clinical Clerks to the Physicians in the wards. The hospital has been recognised by the Conjoint Board for England as a place where six months of the fifth year may be spent in clinical work. The medical practice of the hospital is also recognised by the University of London, the Apothecaries' Society, and the Army and Navy and Indian Medical Boards. Dean of the Medical School: Dr. L. S. Barrell, from whom particulars of lectures, clinical appointments, and hospital practice can be obtained.

CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST, Victoria Park, E.—During the past year 1052 in-patients have been treated in the wards. The out-patients treated during 1919 numbered 10,955. Address "Secretary of the Medical Committee."

ROYAL CHEST HOSPITAL (for all affections of the heart and lungs), City-road, E.C. (80 beds).—This hospital provides accommodation for 80 in-patients. Expenditure for 1919 £14,699, income £13,605. The attendance of out-patients averages 25,000 annually. Secretary: Mr. A. T. Mays.

THE MOUNT VERNON HOSPITAL FOR TUBERCULOSIS AND DISEASES OF THE LUNGS AND HEART, NORTHWOOD, CENTRAL OUT-PATIENT DEPARTMENT, Fitzroy-square, W.—The hospital contains 110 beds. Number of in-patients, 440; out-patients, 2330. Resident Medical Staff. Clinical Demonstrations are given by the Visiting Medical Staff at the hospital at Northwood. Clinical assistants are appointed to physicians in the wards and in the out-patient department. Secretary: Mr. W. J. Morton. Offices: 7, Fitzroy-square, W.

QUEEN CHARLOTTE'S LYING-IN HOSPITAL AND MIDWIFERY TRAINING SCHOOL, Marylebone-road, N.W.—This hospital receives about 2000 patients annually, besides having a large out-patient department. Medical pupils are received at all times of the year. Pupils have unusual opportunities of seeing obstetric complications and operative midwifery, on account of the very large number of primiparous cases—nearly one-half of the total admissions. Clinical instruction is given on the more important cases which present themselves. Special Lecture-demonstrations are given by members of the staff. Certificates of attendance at this hospital are recognised by all the Universities, Colleges, and licensing bodies. Pupil midwives and monthly nurses are received and specially trained. A Residential College provides accommodation for five men at a time, students and qualified practitioners, and is opposite the hospital, with which it is in telephonic communication. Arrangements have been made for Medical Students to receive the preliminary instruction in Practical Midwifery recommended by the General Medical Council. Women students are received. For further particulars application should be made to Mr. Arthur Watts, Secretary, at the hospital.

THE HOSPITAL FOR WOMEN, Soho-square, W.—In connexion with the out-patient department there has been for some years a well-organised Clinical Department. The appointments are open to qualified medical men and women. Every facility is afforded them by the gynaecologists in the out-patient department of obtaining experience in diagnosis and treatment and the practical use of instruments. Fee for one month £2 2s.; for each subsequent month the same. The hospital contains 68 beds. In the out-patient department there were over 4000 new cases during the past year, the total number of out-patient attendances being 14,500. This large number affords exceptional opportunities for examining and studying most of the varieties of the diseases of women. Applications should be made to the Secretary, Mr. Alfred Hayward.

SAMARITAN FREE HOSPITAL FOR WOMEN, Marylebone-road, N.W.—Qualified practitioners are admitted as clinical assistants to both the in- and out-patient departments. Demonstrations are given daily in both departments. The fees, payable in advance, are £3 3s. for three months. Full particulars may be obtained on application to the Secretary at the hospital. There are 70 beds. Secretary: Mr. G. H. Hawkins.

EAST LONDON HOSPITAL FOR CHILDREN AND DISPENSARY FOR WOMEN, Glamis-road, Shadwell, E.—The hospital maintains 130 cots, and on an average 245 out-patients are seen daily. Clinical instruction is given by the physicians and surgeons to the hospital, which is recognised by the Conjoint Board for England as a school of medical teaching for students in the fifth year of the curriculum. All particulars may be obtained on application to the Secretary. Two clinical clerkships for qualified or unqualified students are open every three months subject to reappointment if desired. Clinical assistants (qualified men only) are from time to time appointed in the out-patient department. Any additional information may be obtained on applying to Mr. W. M. Wilcox, the Secretary, at the hospital.

THE HOSPITAL FOR SICK CHILDREN, Great Ormond-street, W.C.1, contains 240 beds, besides 30 beds at the Branch Hospital, Highgate. The hospital having been recognised by the Conjoint Board for England as a place where, under the new curriculum, six months of the fifth year may be spent in clinical work, the practice is arranged

to meet this need and is open to students of both sexes who have completed four years of medical study and also to qualified medical men and women. The medical staff are recognised by the University of London as teachers in Diseases of Children. Arrangements have also been made with University College Hospital and the London School of Medicine for Women for the routine admission of their students of both sexes to clerkships and dresserships in the wards. Appointments are made every three months to six medical clerkships, which are open to students of the hospital. Clinical instruction is given daily by members of the visiting staff. Fees for hospital practice, one month, £2 2s.; three months, 5 guineas; perpetual ticket, 10 guineas. Clinical Clerks, 1 guinea for one month. Ophthalmological Clerkships.—Clinical Clerks are appointed once a month. Fees £1 1s. for one month's attendance. Pathological Clerkships.—Facilities are afforded for obtaining theoretical and practical instruction in Clinical Pathology and Bacteriology in the Pathological Laboratories. Clerks attend for about four hours daily. Fees: For one month, £3 3s.; for two months, £5 5s.; for three months, £6 6s. A reduction is made in the case of those already holding tickets for general attendance at the hospital. Time so spent in clerking and dressing is recognised by the Universities of London, Oxford, and Cambridge, and by the Conjoint Board for England as part of the approved curriculum for students entering for a final examination. These appointments are open to students of all recognised medical schools. In addition, special courses in post-graduate work are held throughout each term of the year, as well as routine post-graduate instruction daily. Details may be obtained by application to the dean or secretary at the hospital. The medical school is a constituent part of the new London Post-Graduate Association. Acting Secretary: Mr. James McKay.

EVELINA HOSPITAL FOR SICK CHILDREN, Southwark Bridge-road, S.E.—This hospital contains 76 cots and a very extensive Out-patient Department. About ten clinical assistants (either sex), to work with the Honorary Medical Staff for Out-patients, are appointed quarterly for a period of three months; there is no salary attached to these posts; but, on the other hand, no fees are charged. Secretary: H. C. Staniland Smith.

VICTORIA HOSPITAL FOR CHILDREN, Tite-street, Chelsea, S.W.—The hospital contains 104 beds and has a large out-patient department (over 1200 weekly); the home at Broadstairs has 50 beds. Out-patients are seen as under:—Diseases of the Eye: Tuesday, 2 P.M. Diseases of the Skin: Wednesday, 1.30 P.M. Whooping-cough Cases: Friday, 2.30 P.M. Dental Cases: Thursday, 1.30 P.M. Medical and Surgical Cases: Mornings at 9.30. Accidents and urgent cases are admitted at any time. Secretary: Mr. H. G. Evered.

QUEEN'S HOSPITAL FOR CHILDREN (*late North-Eastern Hospital for Children*), Hackney-road, Bethnal Green, E.2. (Telephone 305 Dalston.) For the sick children of the poor under 14 years of age. Established 1867. 134 beds in London and 36 at the seaside branch. "Little Folks" Home, Bexhill.—During the past year 1481 in-patients and 53,119 out-patients (attendance 107,075) were received. The surgeons attend on Tuesdays and Wednesdays at 1.45 P.M. and Fridays and Saturdays at 9.30 A.M.; the physicians daily at 1.45 P.M., except Saturday, 9.30 A.M., and Wednesday and Friday, 9.30 A.M., as well as 1.45 P.M. The practice of the hospital is open to students by arrangement with the medical staff. Applications should be made to the Secretary, Mr. T. Glenton-Kerr.

BELGRAVE HOSPITAL FOR CHILDREN, Clapham-road, S.W.—Clinical Assistants (men or women) are from time to time appointed to the members of the Visiting Staff attending in the Out-patient Department at this hospital, and facilities are given for attendance in the wards.

ALEXANDRA HOSPITAL FOR CHILDREN WITH HIP DISEASE, Queen-square, W.C.—At this hospital students who have obtained a recommendation from their teachers can attend to see the practice. The out- and in-patients' clinic is held on Mondays and Thursdays at 3 P.M.

ROYAL LONDON OPHTHALMIC HOSPITAL (Moorfields, 1804-1899). City-road, E.C. 138 beds.—This hospital, known as Moorfields Eye Hospital, was moved in 1899 to larger buildings in City-road. There were 2339 in-patients, the out-patients were 41,725, of whom 36,101 were new

out-patients, and the attendances were 98,186. Operations are performed daily from 10 A.M. to 1 P.M., and four surgeons attend on each day. Students are admitted to the practice of the hospital. Fee for six months, £3 3s.; perpetual, £5 5s. Special courses of instruction, which extend over a period of five months are given by members of the Surgical Staff; beginning in October and March. A composition fee of 24 guineas (£25 4s.) will entitle students to a perpetual ticket, and will admit them once to all the lectures and classes and to the examination for the hospital's full certificate. Students of the hospital are eligible for the offices of house surgeon or clinical and junior assistants. Junior assistants are appointed every three months. Any further information will be furnished by Mr. Robert J. Bland, Secretary Superintendent.

ROYAL WESTMINSTER OPHTHALMIC HOSPITAL, King William-street (next door to Charing Cross Hospital), Strand, W.C.2.—The hospital contains 40 beds. Out-patients, who number over 13,000 annually, are seen daily at 1 P.M., and operations are performed in the theatre at 3 P.M. The practice of the hospital is open to both men and women practitioners and students. Clinical evenings, at which interesting cases are shown and discussed, are held twice each term at 8 P.M. In addition to the ordinary clinical instruction, a systematic course of Lectures and Practical Classes commences in October, January, and May. Lectures in this course are given daily (except on Saturday) at 4.30 P.M., including all subjects required by candidates for the D.O.M.S. R.C.P. & S. Eng., Part II., and practical instruction is given in Operative Surgery and Ophthalmic Pathology and Bacteriology. Fees: One month, £1 1s.; three months, £2 2s.; six months, £3 3s.; perpetual, £5 5s.; composition fee for perpetual ticket and attendance at classes (except Operative Surgery and Pathology, for which fee in each case is £2 2s. per course), £10 10s. Students of the hospital are eligible for appointment as house surgeon, assistant house surgeon, refraction assistant, and senior or junior clinical assistant. Full details can be obtained on application to the Dean.

ROYAL EYE HOSPITAL, St. George's-circus, Southwark, S.E.—There are 40 beds and 2 cots. There were 56,377 attendances in the Out-patient Department last year, and the new patients numbered 22,654. Out-patients are seen daily 1.30 to 2.30 P.M. Post-graduate course: The new term beginning in October. Dean: Mr. A. D. Griffith.

CENTRAL LONDON OPHTHALMIC HOSPITAL, Judd-street, St. Pancras, W.C.—This hospital has 40 beds and possesses facilities for clinical teaching daily. Classes of instruction in the use of the ophthalmoscope, with demonstrations on cases, and also classes on refraction and other subjects are given during the winter months, commencing in October. The out-patient work begins at 1 o'clock, and operations are performed daily between 2 and 4 o'clock. This school is recognised as a teaching institution by the Universities of London and Oxford, and the Conjoint Board of the Royal Colleges of Surgeons and Physicians. The school has also undertaken to receive a portion of the pupils of the University College Hospital for the purposes of ophthalmic training. The Pathological and Bacteriological Laboratories have been rendered available for the use of any ophthalmic surgeons who desire to send specimens for examination. A small fee is charged for a report. Secretary: H. R. S. Druce.

WESTERN OPHTHALMIC HOSPITAL, Marylebone-road, N.W.—16 beds. Out-patient attendances 20,000. Both In-patient and Out-patient Departments of this Hospital are open to medical graduates. Fees £1 1s. per three months. Honorary Secretary: W. H. Burleigh.

HOSPITAL FOR DISEASES OF THE THROAT, Golden-square, W. (with which is amalgamated The London Throat Hospital, Great Portland-street).—Clinical instruction in the diagnosis and treatment of disease is given daily in the out-patient department from 2 to 5 P.M., and on Tuesdays and Fridays from 6.30 to 9 P.M. The hospital contains 60 beds for in-patients. There is an annual out-patient attendance of over 60,000. Minor operations are performed Tuesdays, Wednesdays, and Thursdays, at 9.30 A.M. Major operations are performed on Tuesdays, Wednesdays, Thursdays, and Fridays, at 10 A.M. Also Thursdays and Fridays at 2 P.M. Practitioners and medical students are admitted

to the practice of the hospital at a fee of £5 5s. for three months, £7 7s. for six months, or £10 10s. for perpetual studentship. From amongst the students junior clinical assistants are appointed periodically. For terms and further information apply to the Dean, Mr. Lionel Colledge.

CENTRAL LONDON THROAT AND EAR HOSPITAL, Gray's Inn-road.—Clinical lectures: The hospital is open daily to all qualified medical practitioners on presentation of their visiting cards. Demonstrations of the cases and clinical instruction are given daily by the chief surgeon of each clinique. Medical practitioners are invited to visit the wards, and are welcomed both in the operating theatre, when they are desirous of viewing the major operations, and in the out-patient operating room when minor operations are being performed. Clinical lectures are delivered from time to time, particulars of which are given in the medical journals, and at the hospital. Systematic classes and courses of instruction and demonstrations. Three courses of instruction are open to practitioners attending the hospital: First, the course in methods of examination and diagnosis; second, the course of systematic instruction in the diseases of the nose, throat, and ear; and third, the operative surgery class. The course in methods of examination and diagnosis is introductory in character. It comprises lessons of practical teaching in the actual examination of patients and in the manipulation of instruments. Systematic instruction in Diseases is more advanced. It consists of over 30 lessons in all on pathology, diagnosis, and treatment. Minute details in operative surgery are not gone into, as this is left to the operative surgery class. Full syllabus will be sent on application to the Secretary.

THE METROPOLITAN EAR, NOSE, AND THROAT HOSPITAL.—The hospital is in Fitzroy-square, W. The Out-patient Department is opened daily at 2.30 P.M. to all medical practitioners and senior students for acquiring clinical instruction and technical knowledge. Operations upon in-patients are performed on Mondays, Tuesdays, Wednesdays, Thursdays, and Fridays at 10 A.M. Fee for one month's attendance at the hospital £2 2s., and for three months £3 3s. Clinical Assistants are appointed as vacancies occur, and have responsible duties.

ROYAL EAR HOSPITAL.—This Hospital is now the Ear, Nose and Throat Department of University College Hospital. All the clinics are held at the latter Hospital.

ST. MARK'S HOSPITAL FOR CANCER, FISTULA, AND OTHER DISEASES OF THE RECTUM, City-road, E.C. (Founded 1835).—The hospital contains for men and women 56 beds. Operations are performed on Mondays, Wednesdays, and Thursdays at 2.30 P.M. Medical practitioners and students are invited to the operations and to the clinical instruction in the wards and in the out-patient department. Average out-patient attendances, 4283 per year. Average in-patients, 672 per year.

ST. PETER'S HOSPITAL FOR STONE AND OTHER URINARY DISEASES, Henrietta-street, Covent Garden. Established 1860. New Hospital opened 1882.—The hospital contains 30 beds for men and 2 beds for women and children. Medical practitioners and students are invited to the clinical instructions which are given in the wards and out-patient department daily, and to the operations in the theatre on Mondays, Wednesdays and Fridays at 2 P.M. Average beds occupied daily, 30; average out-patients seen daily, 100.

ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN, 49, Leicester-square, W.C.2.—The in-patient department, 40 beds, is at 262, Uxbridge-road, W.12. The out-patient practice is open to the medical profession every day at 2 and every evening (except Saturday) at 6. At the afternoon clinics demonstrations on the different diseases presenting themselves are given. Venereal Diseases, under the Government scheme, are admitted at all clinics. The X ray department is open every afternoon except Saturday. The Chesterfield Lectures are given on Thursdays at 6 P.M., October to March, commencing Oct. 14th. At the end of the course the Chesterfield medal may be competed for by those who have attended three-fourths of the lectures. Special laboratory courses in Pathology and Bacteriology of the Skin may be arranged for.

LONDON LOCK HOSPITAL AND RESCUE HOME.—In the Female Hospital at Harrow-road, W.9, there are 162 beds, and 636 patients were admitted in 1919. In the Male Hospital and Out-patient Department in Dean-street, Soho, W.,

there are 43 beds, which during 1919 accommodated 475 patients. 62,575 out-patients were treated. 12,000 injections of the substitutes for salvarsan were made in 1918. Male patients are seen at 91, Dean-street, on Mondays and Tuesdays from 1 to 2 P.M. and from 6 to 8 P.M.; on Wednesdays from 6 to 8 P.M.; on Thursdays at 11.30 A.M. and 5-7 P.M. (female patients); on Fridays from 5 P.M. (female patients); and on Saturdays from 2 to 4 P.M. (males). Pathological Department, Tuesdays at 6.30 P.M. Days for intravenous injections 91, Dean-street, W. 1, Tuesdays and Saturdays at 9 A.M. (men); women, Thursdays at 5.30 P.M., Fridays at 5.30 P.M. Female patients are seen at 283, Harrow-road, Paddington, Tuesdays and Thursdays at 2 P.M., and irrigations are given every evening from 6 to 8 P.M. Secretary: Henry J. Eason. Head office: 283, Harrow-road, W. 9.

ENGLISH PROVINCIAL ANCILLARY SCHOOLS AND HOSPITALS.

Under this heading we include all the hospitals which are recognised by the English Royal Colleges for a part of the required attendance on medical and surgical practice, for medical clerkships, and surgical dresserships. The list includes nearly every hospital of a general character in the country having more than 150 beds, though occasionally a large hospital is admitted because equally good opportunities are afforded to students at other institutions in its neighbourhood, while a small hospital may be included because no such facilities for study are present elsewhere. The list is arranged alphabetically as to the town where the hospital is located. Most of the largest general hospitals of the kingdom have already been noticed in connexion with the Universities.

BATH ROYAL UNITED HOSPITAL, Bath.—This hospital contains 130 beds, and possesses a fine library. Secretary: Mr. J. M. Sheppard. V.D. Clinics are held on Tuesdays (for women), and on Fridays and Saturdays (for men) from 5 to 7 P.M.

BEDFORD COUNTY HOSPITAL, Bedford.—This hospital has 100 beds, with X Ray and Pathological Departments, and a convalescent home in connexion with the institution. Secretary: Mr. Beauchamp Wadmore.

BRADFORD ROYAL INFIRMARY, Bradford.—This hospital contains 215 beds. The material passing through the surgical wards consists of major operations, chiefly abdominal, and gynaecological work, and affords excellent facilities for either students or post-graduates. Plans for a new hospital of 382 beds have been adopted, and the building operations will be commenced as soon as the funds in hand will allow.

ROYAL SUSSEX COUNTY HOSPITAL, Brighton (220 beds).—This hospital affords ample facilities for students, possessing a large out-patient department, and a well-appointed clinical research and bacteriological department. The hospital does not take resident pupils, but out-pupils may attend the practice of the hospital for any period not exceeding two years on payment in advance of such a fee, not exceeding 20 guineas, as the Board of Management shall direct.

KENT AND CANTERBURY GENERAL HOSPITAL, Canterbury.—The hospital contains 110 beds. Pupils of the staff are admitted to the practice of the hospital. Operations four days of the week. There is an Ophthalmic Department, a Venereal Clinic, an Orthopaedic Department, &c. Secretary, Mr. F. P. Carroll.

COVENTRY AND WARWICKSHIRE HOSPITAL, Coventry (established 1840).—This hospital contains 335 beds, and a new wing as well as theatre and kitchens have been added. Clinical students are received, and there are paying wards. Secretary: Miss R. Hooper.

DERBYSHIRE ROYAL INFIRMARY, Derby.—This hospital contains 320 beds. It was founded in 1810, and was entirely rebuilt and enlarged 1892-1915 on the most modern lines at a cost of over £144,000. There is a separate ophthalmic block of 33 beds, a separate children's block of 34 beds, and a special department for gynaecological cases. There are three resident house surgeons and a resident house physician. There are also well-equipped orthopaedic, X ray, electrical, and Finsen light departments. Registered medical students are admitted to witness the medical and surgical practice on payment of 10 guineas annually.

ROYAL DEVON AND EXETER HOSPITAL, Exeter.—The hospital contains 200 beds, extending to 300 in 1922 (including special children's ward) and has a good library, museum, dissecting room, and post-mortem room. Attendance on the practice of this hospital qualifies for all the examining boards. There is also a Private Nursing Staff attached to the hospital. For particulars as to fees, &c., apply to the Matron. A new wing was added in 1897. Arrangements may be made by which gentlemen in practice desiring to increase their qualifications may have the use of the museum and library and other facilities and by which students may attend midwifery. A new Operating Theatre was opened in 1906 (the gift of Mrs. Nosworthy of Newlands, Dawlish, Devon). The Electrical Treatment Department (the gift of Mrs. M. A. Sanders) was opened in 1907 by Lady Duckworth-King. A department was opened in 1917 for the treatment of genito-urinary diseases; there are three sessions per week, two for men at 3 P.M. and 7 P.M., and one for women at 3 P.M.

WEST OF ENGLAND EYE INFIRMARY, Exeter.—Secretary: Mr. W. W. Beer. The infirmary contains 64 beds. Students of the Exeter Hospital can attend the practice of the Eye Infirmary. Patients for the year ending Michaelmas, 1919, 2664. A ward is set aside for newly-born babies suffering from infectious eye diseases. The mothers are accommodated with their babies.

GLOUCESTERSHIRE ROYAL INFIRMARY AND EYE INSTITUTION, Gloucester.—This hospital, which was granted the title of "Royal" on the occasion of King Edward VII.'s visit to Gloucester in the year 1909, has 140 beds. Secretary: Captain G. Hurford. In-patients, 1709; out-patients, 7000. An electrical and massage department has been established and venereal and neurological clinics opened. Also ear, nose and throat department.

NORTH STAFFORDSHIRE INFIRMARY, Hartshill, Stoke-on-Trent.—The New Infirmary, opened in 1869, is built on the pavilion plan, has accommodation for about 250 patients, including Children's wards, and a special department for the treatment of Diseases of the Eye, a special X Ray and Electrical Department, a special department for the treatment of Diseases of the Ear, Nose, and Throat, a special orthopaedic department, and venereal diseases clinics, so that there are excellent facilities for acquiring a practical knowledge of the profession. During the last six years the sum of £35,000 has been spent on new buildings and alterations. A new Out-patient Department, costing £12,000, a new Children's Ward of 30 beds, a new Pathological Department, and a second large Operation Theatre are amongst the structural improvements already completed. The whole institution is now equipped in a thoroughly up-to-date manner. Secretary and House Governor: Mr. W. Stevenson.

HULL ROYAL INFIRMARY, Hull.—This hospital contains 256 beds, and since its establishment in 1782 until the erection of the circular wards in 1907 has undergone steady additions and improvements. A branch convalescent home and sanatorium for consumption at Withernsea are special features of the charity.

LEICESTER ROYAL INFIRMARY, Leicester.—Instruction in the infirmary for first-year students is duly recognised by the various examining bodies. At the General Infirmary there are 230 beds, and at the Children's Hospital in connexion 70; total 300. A new wing containing 100 beds was recently opened by H.R.H. the Duchess of Argyll. A reconstruction scheme has been carried out, and £120,000 spent on bringing the accommodation of the institution to a modern standard of efficiency. This scheme has included the provision of two modern operating theatres, and a self-contained out-patients' department. The Children's Hospital has been reconstructed and enlarged by the addition of a third ward at a cost of £14,500. Open-air balconies on all three floors are a feature. A central sterilising department has been provided. Pathological Laboratories and post-mortem rooms have recently been opened at a cost of £11,000, also an orthopaedic out-patient department at a cost of £9500, £5000 of which was provided by the Freemasons of the province as their war memorial. The Nurses' Home is at present undergoing enlargement for 60 additional bedrooms. A new south-west wing, to contain 100 beds, has been approved by the Governors and will shortly be proceeded with. Funds are being raised for the

foundation of a City University, and a splendid site has been presented by Mr. T. Fielding Johnson, J.P., an ex-chairman of the Royal Infirmary. There are eight resident salaried medical officers at the Infirmary—viz., four house surgeons, one house physician, one assistant house physician, and two dressers. Dressers are given an honorarium. House Governor and Secretary: Mr. Harry Johnson.

NORTHAMPTON GENERAL HOSPITAL, Northampton.—Two new wings were opened in 1904 and the old buildings entirely renovated and rearranged. The number of beds is 231, 34 of which are occupied by discharged disabled pensioners. Non-resident pupils are received and have every opportunity of acquiring a practical knowledge of their profession. The fee is £10 10s. Pupils can be received at any time. An up-to-date Pathological Laboratory has recently been erected.

NORFOLK AND NORWICH HOSPITAL, Norwich.—This hospital has at present 350 beds. There is a convalescent home at Cromer, and a large staff of visiting nurses is maintained. Since January last Post-graduate Courses have been held at this institution, and will be continued next year during January, February, March, and April. Secretary: Mr. Frank Inch.

NOTTINGHAM GENERAL HOSPITAL.—At the present time there are 233 beds available for civilian patients. The accommodation of sick and wounded soldiers from overseas was a great feature at this hospital, which is fully equipped in every branch of medicine and surgery.

SOUTH DEVON AND EAST CORNWALL HOSPITAL, Plymouth.—This hospital contains 183 beds (12 of which are for Venereal Diseases in a separate building). There is also an Out-patient Venereal Diseases Clinic. There is a Pathological Laboratory, Special Departments for X ray and Finsen light, an Out-patient Orthopaedic Clinic under the Ministry of Pensions, also a civil Orthopaedic Department. Pensioners are also received as in-patients. The Hospital is a centre for the treatment of Tropical Diseases.

ROYAL HOSPITAL, Portsmouth (founded 1847).—The number of beds is 160. The hospital has X Ray and Massage Departments. The hospital is a preparatory School of Medicine and Surgery; the attendance of pupils at this hospital is recognised by the Examining Boards. Particulars of the Secretary at the hospital.

ROYAL BERKSHIRE HOSPITAL, Reading.—This hospital, which contains 220 beds, has been recently enlarged, the additions including a new Out-patient Department, a Casualty Department, an X Ray Department, Electro-Therapeutic and Massage Department, a Laboratory, an Eye Theatre, and Eye Wards.

SALISBURY GENERAL INFIRMARY, Salisbury.—This hospital contains 145 beds. In-patients, 123 daily average; out-patients, 620, including ophthalmic cases 253 and X ray cases 619; attendances on 5903 casuals. Secretary: Mr. S. B. Smith.

ROYAL SALOP INFIRMARY, Shrewsbury.—This hospital has 160 beds. In-patients, 1387; out-patients, 1521; out-patients' attendances for the year, 17,613. A site has been purchased adjoining the present Infirmary structure, and it is proposed to erect an annexe for children thereon. Secretary: Mr. Alfred Sugden.

ROYAL SOUTH HANTS AND SOUTHAMPTON HOSPITAL, Southampton.—This hospital contains 130 beds. In-patients, 2112; out-patients, 9602. Secretary: Mr. T. A. Fisher Hall.

STAFFORDSHIRE GENERAL INFIRMARY, Stafford.—This hospital has 87 beds. In-patients, 828; out-patients, 2269. Secretary: Lieutenant A. E. Collins.

ROYAL HANTS COUNTY HOSPITAL, Winchester.—This hospital has 160 civilian beds. Secretary: Mr. Herbert Maslen.

WOLVERHAMPTON AND STAFFORDSHIRE GENERAL HOSPITAL, Wolverhampton.—There are 210 beds. Special departments for Children, Gynaecology, Ear, Throat, and Nose Diseases, Electro-therapeutic and X ray, Venereal Disease, and Pathological departments. There is an excellent library. The resident officers are a resident medical officer and three house surgeons. Pupils are allowed to witness the whole of the practice of the hospital and to be present at operations and have every opportunity of acquiring a

practical knowledge of their profession. A course of Practical Pharmacy is given by the dispenser. Fees on application. Applications should be made to the Secretary of the Medical Committee.

WORCESTER GENERAL INFIRMARY, Worcester.—This hospital has 132 beds (temporarily reduced to 70). Pupils are taken by members of the Honorary Medical and Surgical Staff. Number of operations last year 893. New X Ray and Electrical Departments have been erected and are now in use. Additional accommodation for the Honorary Staff and Out-patients and also an Outdoor Shelter in connexion with the Children's Ward have been built as a memorial to King Edward VII. In-patients, 900; out-patients, 2980. Secretary: Mr. E. J. Holland.

YORK COUNTY HOSPITAL, York.—This hospital contains 186 beds. There are balconies for outdoor treatment and two installations of X Ray apparatus. A Venereal Diseases Clinic is held.

SCHOOL OF THE PHARMACEUTICAL SOCIETY OF GREAT BRITAIN.—The subjects of the Qualifying examination of the Pharmaceutical Society are:—Part 1: (a) Chemistry; (b) Physics; (c) Botany. Part 2: (a) Materia Medica; (b) Pharmacy, including Posology and the Translation and Dispensing of Prescriptions; (c) The law relating to the keeping, selling, and dispensing of poisons and poisonous substances. Fee, 12 guineas; for each subsequent examination after failure, 3 guineas. The advanced or Major examination (for registration as "pharmaceutical chemist") includes botany, chemistry and physics, practical chemistry, and materia medica. Fee, 3 guineas. The inaugural address will be delivered on Wednesday, Oct. 6th. Medical students are admitted to the lectures and laboratory work in any or all the courses. Certificates of instruction in this school are received by the Conjoint Board of the Royal Colleges and by the University of London. As we announced in our issue of August 21st, p. 425, courses are now instituted in technical schools to prepare students for the examinations of the Pharmaceutical Society. Application for admission to the school, or for further information, may be made to the Dean, Professor Greenish, 17, Bloomsbury-square, London, W.C.1.

II.—SCOTLAND.

THE UNIVERSITIES.

UNIVERSITY OF EDINBURGH.

Four Degrees in Medicine and Surgery are conferred by the University of Edinburgh—viz., Bachelor of Medicine (M.B.), Bachelor of Surgery (Ch.B.), Doctor of Medicine (M.D.), and Master of Surgery (Ch.M.). The degree of Bachelor of Surgery cannot be conferred on any person who does not at the same time obtain the degree of Bachelor of Medicine, and similarly the degree of Bachelor of Medicine is not conferred on any person who does not at the same time obtain the degree of Bachelor of Surgery.

No one is admitted to the degrees of *Bachelor of Medicine* and *Bachelor of Surgery* who has not been engaged in Medical and Surgical study for five years. No course of lectures will be allowed to qualify unless the lecturer certifies that it has embraced at least 100 lectures, or 50 lectures, as may be required by the regulations, and that the student has also duly performed the work of the class.

Candidates for the degrees of M.B. and Ch.B. must have attended for at least three academic years the medical and surgical practice either of the Royal Infirmary, Edinburgh, or of a general hospital elsewhere which accommodates not fewer than 80 patients and possesses a distinct staff of physicians and surgeons. They must have attended Clinical Surgery during a course or courses extending over not less than nine months, and courses of instruction in all the subsidiary subjects. They must have personally conducted, under the superintendence of a registered medical practitioner, 20 cases of labour at least.

With respect to the places and institutions at which the studies of the candidate may be prosecuted the following regulations have effect:—Two of the five years of medical study must be spent in the University of Edinburgh. The

remaining three years may be spent in any University of the United Kingdom, or in any Indian, Colonial, or Foreign university recognised for the purpose by the University Court, or in such medical schools or under such teachers as may be recognised for the purpose by the University Court. Of the subjects of study—viz., Anatomy, Practical Anatomy, Chemistry, Practical Chemistry, Materia Medica, Physiology, Practical Physiology, Practice of Medicine, Surgery, Midwifery and Diseases of Women, Pathology, Practical Pathology, Physics, Botany, Zoology, Medical Jurisprudence, and Public Health—not less than one-half must be taken in the University of Edinburgh, which corresponds to the two years above referred to.

Women are admitted to graduation in medicine under practically the same conditions as men.

The fee to be paid for the degrees of Bachelor of Medicine and Bachelor of Surgery is £23 2s., and the proportion of this sum to be paid by a candidate at each division of the examination shall be as follows—viz.: For the First Division of the Examination (Botany, Zoology, Physics, and Chemistry), £6 6s.; for the Second Division (Anatomy and Physiology), £5 5s.; for the Third Division (Pathology and Materia Medica and Therapeutics), £4 4s.; and for the Final Division (Surgery and Clinical Surgery, Medicine and Clinical Medicine, Midwifery, Clinical Gynaecology, and Forensic Medicine and Public Health), £7 7s.

Bachelors of Medicine and Bachelors of Surgery may proceed to the degrees of *Doctor of Medicine* and *Master of Surgery* after they have spent one year in the medical or surgical wards respectively of a hospital, or the Military or Naval Medical Services, or in scientific work bearing directly on their profession, or two years in practice other than practice restricted to surgery. In each case an examination must be passed and a thesis submitted for approval of the Faculty. The fee to be paid for the degree of M.D. is £15 15s., and the fee to be paid for the degree of Ch.M. is £15 15s.

A diploma in Tropical Medicine and Hygiene (D.T.M. and H.) is granted to graduates in Medicine and Surgery of the University of not less than six months' standing, and to Registered Medical Practitioners who, having resided in a tropical country, may be approved by the Senatus, on the recommendation of the Faculty of Medicine.

Diploma in Psychiatry.—Courses of instruction have also been instituted for a Diploma in Psychiatry, open to all legally qualified Medical Practitioners who conform with the Regulations. There shall be two examinations for the Diploma, the first comprising the subjects of Anatomy of the Nervous System; Physiology, Histology, and Chemistry of the Nervous System; Pathology of the Brain and Nervous System; Psychology, Lectures, and Demonstrations; and the second examination comprising the subjects of Clinical Psychiatry, Clinical Neurology, Experimental Psychology, Advanced Course in one of the subjects of Part I. (including Advanced Bacteriology). The fee for each examination shall be £6 6s.

Diploma in Public Health (D.P.H. Univ. Edin.).—Courses of instruction have been instituted for a Diploma in Public Health. There are two examinations, the fee for each being £6 6s.

The University of Edinburgh is especially rich in scholarships and prizes in medical subjects. Full particulars can be obtained from the Dean of the Medical Faculty.

SCHOOL OF MEDICINE OF THE ROYAL COLLEGES, Edinburgh.—The number of students varies much in the classes and subjects. It is within the limit to say that before the war about 1000 students availed themselves each session of the opportunity of attending the school. The lectures qualify for the University of Edinburgh and other Universities, the Royal Colleges of Physicians and Surgeons of London, Edinburgh, and Dublin, the Faculty of Physicians and Surgeons of Glasgow, and other Medical and Surgical and Public Boards.

The practical classes and laboratories will open and the lectures commence on Oct. 6th.

In accordance with the statutes of the University of Edinburgh one-half of the qualifying classes required for graduation may be attended in this school. The regulations require that the fee for any class taken for graduation in Edinburgh shall be the same as that for the corresponding class in the University. The whole education required for

graduation at the University of London may be taken in this school.

Special courses of instruction for dental students are also included in the curriculum of this school.

The minimum cost of the education in this School of Medicine for the Triple Qualification of Physician and Surgeon from the Royal Colleges of Physicians and Surgeons of Edinburgh and the Faculty of Physicians and Surgeons of Glasgow, including the fees for the Joint Examinations, is about £130, payment of which is distributed over the period of study. There is no composition fee.

Further particulars regarding the school, also its calendar, may be had on application to the Dean of the School, 11, Bristo-place, Edinburgh.

Clinical Instruction.—**ROYAL INFIRMARY, Edinburgh.**—This hospital has 921 beds and 42 cots for children. Courses of Clinical Medicine and Surgery are given by the physicians and surgeons to male and female students. Special instruction is given on Diseases of Women, Physical Diagnosis, Diseases of the Skin, Diseases of the Eye, the Ear, the Larynx, and the Teeth. Separate wards are devoted to Venereal Diseases, Diseases of Women, Diseases of the Eye, the Ear, Throat and Nose, and the Skin, and also to cases of Incidental Delirium or Insanity. There are also large and complete Medico-Electrical and X Ray and Bathing Departments. Post-mortem examinations are conducted in the anatomical theatre by the pathologist and his assistants, who also give practical instruction in Pathological Anatomy and Histology. The fees for hospital attendance are as follows—viz.: Perpetual ticket, in one payment, £12; annual ticket, £6 6s.; six months, £4 4s.; three months, £2 2s.; monthly, £1 1s. Separate payments amounting to £12 12s. entitle the student to a life ticket. No fees are paid for any medical or surgical appointment. The appointments are as follows: 1. Resident physicians and surgeons are appointed and live in the house free of charge. The appointment is for six months, but may be renewed at the end of that period by special recommendation. 2. Non-resident house physicians and surgeons and clinical assistants are appointed for six months. The appointment may be renewed for a like period by special recommendation. 3. Clerks and dressers are appointed by the physicians and surgeons. These appointments are open to all students and junior practitioners holding hospital tickets. 4. Assistants in the Pathological Department are appointed by the pathologist.

ROYAL HOSPITAL FOR SICK CHILDREN, Sciennes-road, Edinburgh.—This hospital contains 120 beds, and is fitted with every modern improvement. A fully equipped outpatient department (medical and surgical) is conducted daily in a building adjoining the hospital. Systematic courses of instruction, which qualify for graduation in the Edinburgh University and elsewhere, are given from time to time throughout the year by the staff. Students may enter at any time. Full particulars can be obtained from the Registrar at the hospital.

EYE, EAR, AND THROAT INFIRMARY OF EDINBURGH, 6, Cambridge-street, Lothian-road.—Clinical Lectures and Instruction are given in this institution, which is open at 1 o'clock daily for outdoor patients for Eye Diseases; Mondays, Thursdays, and Saturdays at 12 noon, and Tuesdays and Fridays at 4 p.m. for outdoor Ear, Nose, and Throat Patients. Special Practical Ophthalmoscopic Classes by arrangement. Patients whose diseases require operations or more than ordinary care are accommodated in the house. Secretary: Mr. J. P. Watson, W.S., 32, Charlotte-square.

Post-Graduate Instruction.—In connexion with the University and Royal Colleges short advanced courses for Graduates will be held during the Summer and Autumn Terms and the Summer Vacation provided a certain minimum number of Graduates enter for them, and, in certain courses, a maximum limit will also be imposed. The courses will be conducted by teams of teachers, and the following subjects will be included: Clinical Therapeutics, Tuberculosis, Diseases of the Blood, Diseases of the Renal System, Diseases of the Alimentary System, Diseases of the Circulatory System. Diseases of the Ductless Glands, Abdominal Surgery, Genito-Urinary Surgery, Surgery of Children, Clinical Gynaecology and Clinical Obstetrics,

Child Welfare, Diseases of the Larynx, Ear, and Nose, Ophthalmoscopy and Errors of Refraction, Venereal Diseases, Advanced Bacteriology, Advanced Medical Anatomy, Advanced Surgical Anatomy. Arrangements will also be made, if necessary, for special instruction in Antenatal Maternity Work, Psychiatry, and Dermatology. Particulars in regard to the courses—dates of commencement, fees, &c.—may be had on application to the Honorary Secretary, Post-Graduate Courses in Medicine, University New Buildings, Edinburgh.

UNIVERSITY OF GLASGOW.

The University of Glasgow is both a teaching and a degree-granting body, but admits to graduation only candidates whose preliminary examination and course of study conform to its own regulations. Within certain limits instruction given by recognised medical schools and teachers may be accepted, but not less than one-half of the subjects other than clinical must be taken in this or some other recognised university, and at least two years of the course must be taken in Glasgow University. Six degrees, open both to men and women, are conferred: M.B. and Ch.B. (always conjointly), M.D. and Ch.M.; B.Sc. in Public Health; D.Sc. in Public Health; and B.Sc. in Pharmacy. A Preliminary Examination must be passed in (1) English, (2) Latin, (3) Elementary Mathematics, and (4) Greek, or French, or German, or Italian, with possible options to students whose native language is not English. Candidates taking the University preliminary examination are not obliged to pass in all the four subjects at one examination, but must do so at not more than two occasions.

For the degrees of M.B. and Ch.B. a curriculum of five years is required. The candidate must, during his curriculum, have attended a course or courses of instruction in each of the following subjects of study, extending over not less than the number of terms specified in each case, and including such class examinations as may be prescribed in connexion with the several courses:—Chemistry (including Organic Chemistry), two terms; with Practical Chemistry, one term; Physics (with practical work), one term; Botany (with practical work), one term; Zoology (with practical work), one term; Anatomy and Practical Anatomy, five terms; Physiology and Practical Physiology, three terms; Materia Medica and Therapeutics (together or separately), each subject, one term; Pathology and Practical Pathology, three terms; Medical Jurisprudence and Public Health (together or separately), each subject, one term; Midwifery and Diseases peculiar to Women and to Infants, two terms; Surgery, two terms; Medicine, two terms. Candidates must attend at least three years the Medical and Surgical Practice of a recognised hospital accommodating at least 80 patients and having a distinct staff of physicians and surgeons. At least nine months' hospital attendance is required on both Clinical Surgery and Clinical Medicine, and the student must have acted for six months as clerk in medical and dresser in surgical wards, and must have had six months' outdoor practice; he must also have attended a course of Mental Diseases and of Practical Pharmacy (25 meetings), must have been properly instructed in Vaccination at a public vaccination station, and must have attended at least 20 cases of labour and the Practice of a Lying-in Hospital. The University also requires further study in various special subjects.

There are four Professional Examinations, the first comprising Botany, Zoology, Physics, and Chemistry; the second comprising Anatomy and Physiology; the third comprising Materia Medica and Therapeutics and Pathology; and the fourth or final, comprising Medical Jurisprudence and Public Health, Surgery and Clinical Surgery, Practice of Medicine and Clinical Medicine, and Midwifery and the Diseases peculiar to Women and to Infants.

The degrees of M.D. (Doctor of Medicine) and Ch.M. (Master of Surgery) are higher degrees in Medicine and Surgery respectively, and candidates (not under 24 years of age) who have previously obtained the double bachelorship may be admitted to either M.D. or Ch.M. on completing the after course prescribed, including an examination in Clinical Medicine for M.D. and an examination in

Surgical Anatomy, operations on the dead body, and Clinical Surgery for Ch.M.

In 1919 new chairs were instituted in Bacteriology, Organic Chemistry, and Physiological Chemistry.

Fees.—The Fees for M.B. and Ch.B. are £23 2s. The class fee in each subject of the curriculum for M.B. and Ch.B. is £2 2s., £3 3s., or £4 4s., and the present fee for hospital attendance is £7. The fee for M.D. is £15 15s., and for Ch.M. £15 15s.

The great majority of the students take their hospital course at the Western Infirmary, or the Royal Infirmary, where clinical instruction is given by professors of the University and others. Clinical instruction on Fevers is given at Ruchill and Belvidere Hospitals, while special courses, largely of a practical nature and embracing work in Hospital or Asylum wards, are conducted by University Lecturers on the Ear, the Throat and Nose, Dermatology, Ophthalmology, Venereal Diseases, Tuberculosis, and Insanity. Queen Margaret College, sometime conducted as a separate institution for the higher education of women, was made over to the University in 1892, and in it medical classes for women are conducted under University professors and other lecturers appointed by the University Court, whilst for clinical instruction female students mostly attend the Royal Infirmary.

In this University Bursaries and Prizes to the annual amount of over £1000 are appropriated to students in the Medical Faculty, and there are also several Scholarships and Fellowships which may be held by medical students who have gone through the Arts course. A full list will be found in the University Calendar.

THE ANDERSON COLLEGE OF MEDICINE, Dumbarton-road, Glasgow, W.—Courses are given which qualify for all the licensing boards and for the Universities of London, Durham, Edinburgh, and Glasgow (the latter two under certain conditions). Candidates for the Licence in Dental Surgery can obtain the full medical curriculum in Anatomy, Chemistry, Physiology, Surgery, Practice of Medicine, and Materia Medica. The courses special to Dentistry are also conducted in the Anderson College of Medicine.

The buildings are situated in Dumbarton-road, immediately to the west of the entrance to the Western Infirmary, and adjoining the University. Extensive accommodation is provided for Practical Anatomy, Practical Chemistry, Practical Botany, Practical Zoology, Practical Physiology, Practical Pharmacy, Operative Surgery, and Public Health. Ample provision has also been made for the comfort of students.

Women students are admitted on the same terms as men.

The Carnegie Trust extends its benefactions to students of the Anderson College of Medicine. Full particulars may be obtained from Sir W. S. McCormick, the Carnegie Trust Offices, Merchants' Hall, Edinburgh.

Communications relating to the College to be addressed to the Secretary of the Medical Faculty, The Anderson College of Medicine, Glasgow, W. Communications relating to the Preliminary Examination in General Education to be addressed to Mr. Hugh Cameron, M.A., F.E.I.S., Educational Institute Office, 34, North Bridge-street, Edinburgh. Communications relating to the Triple Qualification to be addressed to Mr. Walter Hurst, Royal Faculty Hall, 242, St. Vincent-street, Glasgow.

The Winter Session will open on Friday, Oct. 15th, 1920.

ST. MUNGO'S COLLEGE AND GLASGOW ROYAL INFIRMARY.—The classes in St. Mungo's College qualify for the English, Scotch, and Irish Conjoint Boards and, under certain conditions, for the various universities, including the University of London. Students who have fulfilled the conditions of the Carnegie Trust as regards Scottish birth or extraction, age (16 years), and Preliminary Examination, are eligible for the benefits of this Trust during the whole course of their studies at St. Mungo's College. The classes are open to male and female students equally. The minimum fees for all the lectures, including hospital attendance, necessary for candidates for the Diplomas of the English or Scotch Colleges of Physicians and Surgeons, amount to £100. Further particulars can be obtained from a syllabus which may be procured free on application to the Secretary of the Medical Faculty, 86, Castle-street, Glasgow.

QUEEN MARGARET COLLEGE (Women's Department of the University).—This is an integral part of the University of Glasgow. The classes are taught by professors of the University and other lecturers appointed by the University Court, and it is governed by the University Court and Senate. The curriculum, regulations, and fees are the same as those of the male students, and the University degrees are open to women on the same conditions as to men. They have access to the University Museum and can borrow books from the University Library, besides having a library of reference in Queen Margaret College. The School of Medicine is a special feature of the College, and gives full preparation for the medical degrees of the University. In July, 1894, for the first time in the history of any Scottish University, women students graduated in medicine in Glasgow University. Over 300 women have now taken the degree of M.B., C.M., or M.B., Ch.B. of the University of Glasgow and 24 the degree of M.D. The women students attend classes in the various University Buildings at Gilmore-hill, Queen Margaret College, the Royal Infirmary, and the Western Infirmary. Excellent facilities for clinical work are given in the Royal and Western Infirmarys, in the Maternity, Royal Sick Children's, and other hospitals. The Arthur Scholarship is open every third year to students of first year; other Bursaries are open in Arts and Medicine; and by an ordinance of the Universities Commissioners women are admitted to certain University bursaries, scholarships, and fellowships. The Winter Session will open on Oct. 18th, but owing to the pressure upon accommodation in classes no new students of Medicine are to be admitted until April, 1921. Applications for entrance at that date should be made before Feb. 1st, 1921.

ROYAL INFIRMARY, Glasgow.—The ancient connexion between the University of Glasgow and the Royal Infirmary was revived in 1911, when four University Chairs and several University Lectureships were established at the infirmary. St. Mungo's College is situated in the infirmary grounds. The infirmary has, including the Ophthalmic Department, 700 beds. There are special beds and wards for diseases of women, of the throat, nose, and ear, skin, venereal diseases, burns and septic cases. The wards are open to Women Students. At the Out-door Department the attendances in 1919 numbered about 146,000. In addition to the large medical and surgical departments there are departments for special diseases—viz., diseases of women, of the throat and nose, of the ear, of the eye, of the skin, and of the teeth. Five house physicians and 12 house surgeons, who board in the hospital free of charge, are appointed every six months. Clerks and dressers are appointed by the physicians and surgeons. As a large number of cases of acute diseases and accidents of a varied character are received these appointments are very valuable and desirable. There is a modern and fully equipped Electrical Pavilion, and year by year the latest and most approved apparatus for diagnosis and treatment has been added. The fees are as follows: (a) For hospital practice, including attendance at the out-door department, at the pathological department, post-mortem examinations, and the use of the museum: Perpetual ticket, £7; six months, £2 2s.; three months, £1 1s.; separate payments amounting to £7 7s. entitle the student to a perpetual ticket, on return of previous season tickets; (b) for Clinical Lectures, six months, £3 10s.; three months, £1 15s.; (c) Vaccination, £1 1s.; Pathology, £4 4s.; Bacteriology, £2 2s.

Post-graduate classes will be held during September in Clinical Medicine, Clinical Surgery, Clinical Gynaecology, Surgical Diagnosis, Urology, Auto-intoxications, Clinical Examination of Urine, Haematology, Diseases of the Skin, Venereal Disease, Diseases of Throat, Nose and Ear, and Electro-therapeutics, X Ray Therapy, and Diagnosis. The fee for attendance at each of these courses is £1 1s.; for any three of them, £2 2s. A Special Course on Diseases of the Eye will be held in the Ophthalmic Institution. Fee for this course £2 2s. Those desirous of joining any of these classes should communicate at once with Dr. J. Maxtone Thom, Superintendent.

GLASGOW WESTERN INFIRMARY.—This hospital adjoins the University of Glasgow. Number of beds upwards of 600. Special wards are set apart for Diseases of Women, Throat, Nose, and Ear, and for Affections of the Skin. In the out-patient department there are special clinics

for Diseases of Women and for Diseases of the Throat, Ear, Teeth, Skin, Venereal Disease, and Electro-therapeutics. The Clinical Courses are given by the physicians and surgeons, each of whom conducts a separate class, and students require to enter their names at the beginning of the session for the class which they propose to attend: Special instruction is given to junior students by tutors or assistants, and clinical clerks and dressers are selected from the members of the class. All the courses of clinical instruction are recognised by the University of Glasgow and the other boards in the kingdom. In the Pathological Department the course is both systematic and practical, also post-graduate courses, and extends through the winter and following summer; these are likewise recognised by the University for graduation. Eighteen resident assistants are appointed annually, without salary, from those who have completed their course. The fee for hospital attendance is £7, and the fees for clinical instruction are £3 3s. for the Winter Session and £2 2s. for the Summer Session. A Clinical Laboratory has been opened, and students receive laboratory instruction from the lecturer on clinical methods. Secretary: J. Matheson Johnston, C.A., 87, Union-street.

A School of Massage, Medical Electricity, and Swedish Remedial Exercises has been established to qualify for the Certificate of the Chartered Society of Massage and Medical Gymnastics.

ROYAL HOSPITAL FOR SICK CHILDREN, Yorkhill, Glasgow.—This institution, which was founded in 1882, consists of: (1) a hospital at Yorkhill containing 250 cots built on an elevated and central site close to the University and opened in July, 1914; (2) a Dispensary, or Out-patient Department, in West Graham-street, opened in October, 1888; and (3) a country branch at Drumchapel, Dumbartonshire, containing 30 cots, opened in 1903. Children treated must not be over 12 years of age and suffering from non-infectious diseases. In the hospital about 5000 children are treated annually. In the Out-patient Department over 12,000 are treated annually, involving nearly 50,000 attendances. There are two lectureships in the University of Glasgow in connexion with the hospital, one on the Medical Diseases of Infancy and Childhood, and the other on Surgery and Orthopaedics in Relation to Infancy and Childhood. These lectureships are held by the Visiting Physician, Dr. Leonard Findlay, and the Visiting Surgeon, Mr. Alexander MacLennan. The lectures are both systematic and clinical, but particularly and chiefly the latter. Information with regard to clinical instruction, lectures, demonstrations, post-graduate study, &c., may be obtained from the Medical Superintendent.

GLASGOW ROYAL MATERNITY AND WOMEN'S HOSPITAL, Rottenrow.—The new hospital, which was opened in 1908, is in point of size the largest of its kind in Britain and has accommodation for 108 patients. A Maternity and Child Welfare Centre has been established in connexion with the hospital, consisting of a complete In-door and Out-door Ante-natal Department and an Infant Consultation Clinic. In 1919 2636 normal cases and 2316 abnormal cases were treated by the hospital in the In-door and Out-door Departments. Secretary: Mr. William Guy, 146, Buchanan-street. Full particulars as to fees and accommodation may be obtained from the House Superintendent at the Hospital.

ROYAL SAMARITAN HOSPITAL FOR WOMEN, GLASGOW.—This hospital, founded in 1886, is one of the largest purely gynaecological hospitals in Great Britain, possessing, as it does, over 90 beds. It offers excellent facilities for clinical instruction in the diseases peculiar to women, treating in the wards and in the out-patient department some 4000 cases per annum. The surgeons, four in number, visit the wards in the mornings. For further information application may be made at the Hospital, or to Thos. Macquaker, honorary secretary, 89, West Regent-street, Glasgow.

GLASGOW LOCK HOSPITAL, 41, Rottenrow.—The Hospital contains 83 beds. During 1919 364 patients were admitted to the wards; 14,187 visits were made by out-door patients at the Dispensary. Classes are held for the clinical instruction of medical students and practitioners. J. Neilson Gray, secretary and treasurer, 65, Bath-street, Glasgow.

GLASGOW OPHTHALMIC INSTITUTION, 126, West Regent-street (29 beds and six cots).—Clinical and systematic course of lectures for students during the winter and summer

sessions. In-patients, 879; out- or dispensary patients, 13,918; total attendances, 34,031. Operations on Wednesdays and Saturdays. This institution is the Ophthalmic Department of the Royal Infirmary. Clinical instruction is given during both summer and winter sessions to men and women students attending the University. During September post-graduate courses will be held in connexion with the Glasgow Royal Infirmary. Secretary and Cashier: R. Morrison Smith, C.A., 135, Buchanan-street, Glasgow.

GLASGOW EYE INFIRMARY, Berkeley-street and Charlotte-street.—This institution, the largest of its kind in Scotland, was founded in 1824. The average number of new patients for the last ten years has been 27,106 and the total number of cases in 1919 was 25,462. The wards and dispensary are recognised by the University of Glasgow for the purpose of instruction in ophthalmology for graduation in medicine. A Venereal Centre is being established. Secretary and Acting Treasurer: Harold John Black, 88, West Regent-street, Glasgow. The medical session opens in October. A Post-graduate Class will be held.

GLASGOW HOSPITAL FOR DISEASES OF THE EAR, NOSE, AND THROAT, 27 and 28, Elmbank-crescent.—12 beds and three cots. New patients, 5508. Attendances at out-patient department 19,023. Admitted to in-door department 392. Clinical instruction is given in connexion with Dr. Connal's course on Diseases of the Ear at Anderson's College and Dr. Syme's course on Diseases of the Throat and Nose at the Western Medical School. A course of post-graduate study has been conducted by the staff of the hospital. Secretary: Mr. P. T. Young.

UNIVERSITY OF ST. ANDREWS (UNITED COLLEGE ST. ANDREWS AND UNIVERSITY COLLEGE, DUNDEE).

Four degrees in Medicine and Surgery are conferred by the University of St. Andrews—viz., Bachelor of Medicine (M.B.), Bachelor of Surgery (Ch.B.), Doctor of Medicine (M.D.), Master of Surgery (Ch.M.), a Diploma in Public Health, and Diploma in Dental Surgery (L.D.S.). The whole curriculum may be taken at University College, Dundee, or the first two years of the course may be taken at St. Andrews and the remaining three years in Dundee. The degrees of M.B. and Ch.B. shall always be conjoined. Before commencing his medical studies each student shall pass a Preliminary Examination in (a) English, (b) Latin, (c) Elementary Mathematics, and (d) one of the following optional subjects: (a) Greek, (b) French, (c) German, (d) Italian, (e) any other approved Modern Language. A degree in Arts or in Science in any of the Universities of the United Kingdom and in some colonial and foreign universities shall exempt from the Preliminary Examination. The Preliminary Examination for graduation in Medicine and Surgery, Arts or Science, of the University of St. Andrews is accepted as equivalent to the Registration Examination required by the General Medical Council (the certificate to include the required subjects). Also the Final Examination for a degree in Arts or Science and the Final Examination for the Diploma of L.L.A.

Degree of Bachelor of Medicine and Bachelor of Surgery.—Candidates must have been engaged in medical study for at least five years. In each of the first four years the candidate must have attended at least two courses of instruction in one or more of the subjects of study specified below, each course extending over a session of not less than five months, either continuous or divided into two terms, or, alternatively, one such course along with two courses, each extending over a session of not less than two and a half months. During the fifth or final year the candidate shall be engaged in clinical study for at least nine months at the Infirmary of Dundee or at one or more of such public hospitals or dispensaries, British or foreign, as may be recognised for the purpose by the University Court. The candidate must have received instruction in each of the following subjects of study, including such examinations as may be prescribed in the various classes—viz.: Anatomy, Practical Anatomy, Chemistry, Materia Medica, Physiology, or Institutes of Medicine, Practice of Medicine, Surgery, Midwifery and the Diseases peculiar to Women and Infants. Pathology, Practical Chemistry, Physics (including the Dynamics of Solids, Liquids, and Gases, and the Rudi-

ments of Sound, Heat, Light, and Electricity), Elementary Botany, Elementary Zoology, Practical Physiology, Practical Pathology, Forensic Medicine, and Public Health. The candidate must have attended for at least three years the Medical and Surgical Practice either of the Infirmary of Dundee or of a General Hospital elsewhere which accommodates not fewer than 80 patients and possesses a distinct staff of physicians and surgeons and is recognised for the purpose by the University Court. Additional subjects of study are Practical Pharmacy, Mental Diseases, Practical Midwifery, Operative Surgery, Vaccination, Children's Diseases, Fevers, Ophthalmology, Diseases of the Ear, Throat, and Nose, Anaesthetics, and Post-mortem Examinations.

With respect to the places and institutions at which the studies of the candidate may be prosecuted the following regulations shall have effect:—1. Two of the five years of medical study must be spent in the University of St. Andrews. 2. The remaining three years may be spent in any University of the United Kingdom or in any Indian, Colonial, or Foreign University recognised for the purpose by the University Court, or in such medical schools or under such teachers as may be recognised for the purpose by the University Court. Women are admitted to graduation in Medicine, subject to certain provisions.

Professional Examinations for the Degrees of Bachelor of Medicine and Bachelor of Surgery.—Each candidate will be examined both in writing and orally, and also clinically where the nature of the subject admits, in the following divisions—viz., first, in Botany, Zoology, Physics, and Chemistry; second, in Anatomy and Physiology; third, in Materia Medica and Pathology and Forensic Medicine and Public Health; and fourth, in Surgery, Clinical and Operative Surgery, Practice of Medicine and Clinical Medicine, and Midwifery and Gynaecology (Systematic and Clinical).

The fee to be paid for the degrees of Bachelor of Medicine and Bachelor of Surgery shall be 22 guineas, and the proportion of this sum to be paid by a candidate at each division of the examination shall be regulated from time to time by the University Court. The fee to be paid for the degree of Doctor of Medicine shall be 15 guineas, and for the degree of Master of Surgery 15 guineas. The whole medical curriculum can be taken in University College, Dundee, or the first two years in United College, St. Andrews.

For further particulars and details as to scholarships and bursaries application should be made to Professor Kynoch, Dean of the Medical Faculty, University College, Dundee.

UNIVERSITY COLLEGE, Dundee.—This College is one of the constituent colleges of the University of St. Andrews. In the medical buildings there are spacious and well-equipped laboratories. The complete medical curriculum can be taken in Dundee. For classes, fees, &c., see under University of St. Andrews.

ROYAL INFIRMARY, Dundee.—The Infirmary contains 408 beds, including special wards for the Diseases of Women, Children, Eye, Ear, and Throat, Skin, and for Obstetric cases. There is in addition an Extern Obstetric Department. There were during last year 17,118 out-patients and 834 home (maternity) patients. The Royal Infirmary offers facilities for practical work to students. Appointments: Six qualified Resident Medical Officers (Male or Female) are appointed every six months and one Obstetric Assistant. Clinical Clerks and Dressers are attached to the Physicians and Surgeons, and students are appointed as assistants in the Pathological Department. There are in connexion with the clinical courses Tutorial Classes in Medicine and Surgery. Instruction is also given in Practical Pharmacy and Materia Medica. Further information can be obtained from the Medical Superintendent.

UNIVERSITY OF ABERDEEN.

The University of Aberdeen grants four degrees in Medicine and Surgery—viz., Doctor of Medicine (M.D.), Master of Surgery (Ch.M.), Bachelor of Medicine (M.B.), and Bachelor of Surgery (Ch.B.).

Degrees of M.B. and Ch.B.—Before commencing his medical studies each student must pass a Preliminary Examination in (1) English, (2) Latin, (3) Mathematics, and (4) one additional language—Greek, French, German, Italian, or such other language as the Senatus may approve.

The curriculum for the degrees extends over a period of five years, during which attendance is required in the following subjects: Botany, Zoology, Physics, Chemistry (Systematic and Practical), Anatomy (Systematic and Practical), Physiology (Systematic and Practical), Materia Medica and Therapeutics, Practical Pharmacy, Pathology (Systematic and Practical), Medical Jurisprudence, Public Health, Surgery, Medicine, and Midwifery.

Candidates must attend for at least three years the medical and surgical practice of a recognised hospital; they must have attended courses of at least nine months in clinical medicine and clinical surgery, and have acted as clerk in the medical and dresser in the surgical wards of a hospital. Attendance is required on the practice of a dispensary or the out-practice of a hospital and also on courses in Mental Diseases, Fevers, Ophthalmology, Post-mortem examinations, Venereal Diseases, and other special subjects. The candidate is also required to have been properly instructed in Vaccination and to have attended at least 20 Midwifery cases.

The fee for the degrees of M.B. and Ch.B. amounts to £23 2s.

Besides the Royal Infirmary, students have the opportunity of attending the following institutions: City Fever Hospital, Sick Children's Hospital, General Dispensary, and Lying-in and Vaccine Institutions, Royal Lunatic Asylum, Ophthalmic Institution, &c.

Degrees of M.D. and Ch.M.—Candidates for either of these degrees must already hold the degrees of M.B. and Ch.B. of Aberdeen. A thesis has to be presented and an examination has to be passed in Clinical Medicine (or in some special Department of Medical Science) or Clinical Surgery, as the case may be.

A diploma in Public Health is granted by the University to graduates in Medicine of a University in the United Kingdom, after a special examination.

Application for further information should be addressed to the Secretary of the Medical Faculty.

Scholarships and Prizes.—In the Faculty of Medicine of the University of Aberdeen there are the following Bursaries, Scholarships, and Prizes:—Bursaries: about 15 Bursaries (competition and presentation) are open each year, of £15 to £30 per annum in value, most of them being tenable for three years. Scholarships: five Post-Graduate Scholarships, value £36 to £160 per annum. Prizes and Medals: 13 Gold Medals and Prizes for proficiency in special departments, &c.

Clinical Instruction is given in the Aberdeen Royal Infirmary (270 beds) by the physicians and surgeons on the staff.

ABERDEEN ROYAL ASYLUM.—Contains, with hospital attached to main institution and agricultural branch, about 950 beds. Clinical instruction is given to students during three months in summer. Clerk and Treasurer, Mr. A. Scott Finnie, 343, Union-street, Aberdeen.

SCOTTISH MEDICAL CORPORATIONS GRANTING DIPLOMAS.

ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH, ROYAL COLLEGE OF SURGEONS OF EDINBURGH, ROYAL FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW.

These Colleges have made arrangements by which, after one series of examinations, held in Edinburgh or Glasgow, or both, the student may obtain the diplomas of the three Bodies.

The three Bodies grant their Single Licences only to candidates who already possess legal qualifications in Medicine or Surgery. Copies of the Regulations for the Single Licence of any of the Bodies may be had on application to the respective secretaries.

Professional Education.—The candidate must produce certificates or other satisfactory evidence of having attended the following separate and distinct courses of instruction: Physics, three months; Elementary Biology, three months; Chemistry, six months; Practical or Analytical Chemistry, three months; Anatomy, during at least six months; Practical Anatomy, twelve months; Physiology, six months;

Practical Physiology, three months; Materia Medica, three months; Pathology (including Practical Pathology), nine months; Practice of Medicine, six months; Clinical Medicine, nine months; Principles and Practice of Surgery, six months; Clinical Surgery, nine months; Midwifery, three months; Gynaecology, one course of not less than 13 meetings; Diseases of Children, one course of not less than 13 meetings; Medical Jurisprudence and Public Health, three months. The certified attendance on lectures, demonstrations, and practical work must not be less than three-fourths of the total number of roll-calls. Every student undergoes a course of Practical Midwifery, but before attending at labours he is required to attend a course of lectures on Surgery and Midwifery and to hold the offices of Clinical Medical Clerk and Surgical Dresser. He must also attend for two and a half months instruction in Practical Pharmacy; the certificate to be signed by the teacher, who must be a member of the Pharmaceutical Society of Great Britain, or the superintendent of the laboratory of a public hospital or dispensary, or a registered practitioner who dispenses medicines to his patients, or a teacher of a class of Practical Pharmacy.

The student must attend for 27 months the Medical and Surgical practice of a public general hospital containing on an average at least 80 patients available for clinical instruction and possessing distinct staffs of physicians and of surgeons. He must act as Surgical Dresser and Medical Clinical Clerk for not less than six months in the wards in each case, and receive practical instruction in administration of anaesthetics. He must attend for six months the practice of a public dispensary especially recognised by any of the above authorities, or the out-patient practice of a recognised general hospital or act for six months as pupil to a registered practitioner who either holds such a public appointment, or has such opportunities of imparting practical knowledge as shall be satisfactory to the cooperating authorities; this attendance should be made after the student has passed the First and Second examinations.

Candidates are also required to attend the following courses: Diseases and Injuries of the Eye, three months; Insanity, three months; Infectious Diseases, three months; Gynaecology, three months; Diseases of Children, three months.

The curriculum lasts for five years, the fifth year being devoted to clinical work.

There are four professional examinations:—

First Examination includes Physics, Chemistry, and Elementary Biology.

Second Examination includes Anatomy and Physiology and Histology; and candidates may be admitted to this examination at the end of the second year of medical study.

Third Examination includes Pathology and Materia Medica with Pharmacology.

Final Examination.—The Final examination shall not be taken earlier than the end of the fifth year of study and shall embrace the following subjects:—Medicine, including Therapeutics, Medical Anatomy, and Clinical Medicine; Surgery, including Surgical Anatomy, Clinical Surgery, and Diseases and Injuries of the Eye; Midwifery and Diseases of Women; and, if not passed previously, Medical Jurisprudence and Public Health, but it is optional to candidates who have passed the Third Examination to be admitted to the subject of Medical Jurisprudence and Public Health on lodging certificates of having attended the necessary course in that subject at any time; but the subjects of Medicine, Surgery, and Midwifery shall be taken together at any time after the end of the fifth Winter Session, provided that a period of 24 months has elapsed since passing the Second Examination. All candidates shall be subjected, in addition to the written and oral examinations, to clinical examinations in Medicine and Surgery, which shall include the Examination of Patients, Physical Diagnosis, the Clinical use of the Microscope, Examination of the Urine and Urinary Deposits, Surgical Appliances, Bandages, Surface Markings, &c. The fees payable for the Final Examination shall be—for the whole examination, £15, for re-entry after rejection, £5, and for the subjects of Medical Jurisprudence and Public Health when taken separately, £5, with £3 for re-entry in that subject.

There are four periods of examination annually: During the ensuing period, three in Edinburgh and one in

Glasgow, in 1920-21. The Registrar in Edinburgh is Mr. D. L. Eadie, 49, Lauriston-place, and the Registrar in Glasgow, Mr. Walter Hurst, 242, St. Vincent-street, to whom fees and certificates must be sent for the respective examinations, and from whom further particulars concerning fees can be obtained.

ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH: THE MEMBERSHIP AND FELLOWSHIP.

In addition to the diplomas granted by the Scottish Conjoint Board the Royal College of Physicians grants its Single Licence to candidates already possessing legal qualifications for professional practice.

The Royal College of Physicians of Edinburgh grants a *Membership* and a *Fellowship*.

Membership.—A candidate, who must be a Licentiate of a British or Irish College of Physicians, or a graduate in medicine of a University, approved by the Council, and 24 years of age, is examined in medicine, therapeutics, and in any branch of the departments of medicine specially professed, such as general pathology, psychology, public health, obstetrics, gynaecology, diseases of children, tropical medicine, or medical jurisprudence. The fee for the Membership is £36 15s., 15 guineas of which will be returned to any successful candidate who was already a Licentiate of the College at the time of qualifying for the Membership.

Fellowship.—The Fellows are selected from the ranks of the *Members*. The fee is £64 18s.

ROYAL COLLEGE OF SURGEONS OF EDINBURGH: THE FELLOWSHIP.

The Royal College of Surgeons of Edinburgh also admits to the examination for its Single Licence any candidates who hold a Diploma in Medicine of any British, Indian, or Foreign university or of any British College of Physicians, or of the Society of Apothecaries of London or Apothecaries' Hall, Dublin, granted under the provisions of the Medical Act, 1886, whose preliminary examination and course of professional study is proved to be sufficient to fulfil the requirements of the College, or to those who have passed a full examination for any of the above. Female practitioners are admitted to the Licence of the College and now to the Fellowship, and the regulations apply to practitioners of either sex.

The Royal College of Surgeons of Edinburgh grants a diploma of Fellowship after examination to the holders of the surgical degrees of diplomas of such British examining bodies, as well as of the holders of such surgical degrees of the Universities of Canada, Australia, New Zealand, and the Indian Empire as are recognised by the College.

The Fellowship.—Candidates for the examination must be 25 years of age and must have been engaged in practice for at least two years. The examination is of a practical nature, partly written and partly *viva voce*, and must include surgery and surgical anatomy, operative surgery, and clinical practice. One optional subject must also be taken, the range of these specialisms covering nearly every branch of medicine. The fee to be paid on entering for examination for Fellowship is £45, £10 of which is remitted to those who already hold the Licentiate of the College. Candidates rejected at the examination obtain repayment of fee less £10 retained for examination expenses. One month's notice of intention to appear for examination must be given by the candidate to Mr. D. L. Eadie, 49, Lauriston-place, Edinburgh, clerk to the College, together with credentials signed by two Fellows of the College, one of whom must be a resident in Edinburgh, otherwise a special application, with six testimonials, must be made to the President and the Council of the College.

THE ROYAL FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW.

Like the preceding corporations, the Royal Faculty of Physicians and Surgeons of Glasgow grants a Fellowship and a Licence to be held as separate qualifications.

Fellowship.—The Fellowship of the Faculty is granted after examination in medicine or surgery, together with an

optional subject, which may be anatomy or physiology or be selected from any special branch of medicine or surgery. 14 days' notice must be given by the candidate of his intention to present himself to Mr. Walter Hurst, the Faculty Hall, 242, St. Vincent-street, Glasgow. The fee for the Fellowship is £30, £10 of which sum are returned to any successful candidate who already holds the Licence of the Faculty. An additional sum of £20 is required in the case of candidates resident within seven miles of Glasgow. In certain circumstances Fellows may be elected as a mark of distinction.

Licence.—The Licence of the Royal Faculty is granted as a separate qualification to qualified practitioners in Medicine after examination in surgery, including surgical anatomy and clinical surgery. The fee is 15 guineas.

SCOTTISH PROVINCIAL ANCILLARY SCHOOLS AND HOSPITALS.

The hospitals which are recognised by the Scottish Conjoint Board, as places where professional study for their diplomas can be pursued are all those institutions which feed the medical faculties of the universities. In addition the Scottish Boards recognise all the places which are recognised by the English Conjoint Board (see p. 451) and the Irish Conjoint Board (see p. 463).

III.—IRELAND.*

THE UNIVERSITIES.

UNIVERSITY OF DUBLIN, TRINITY COLLEGE (SCHOOL OF PHYSIC).

Matriculation.—In order to join the School of Physic students pass a matriculation examination. University students take the Entrance of Trinity College and a Junior Freshman Term or a special Medical Preliminary; Extern Students, any examination recognised by the General Medical Council. The winter courses begin on Oct. 1st.

Degrees in Medicine (M.B.), Surgery (B.Ch.), and Midwifery (B.A.O.).—Candidates for these degrees must be of B.A. standing and must be for at least five academic years on the books of the Medical School, reckoned from the date of matriculation. The Arts course may be taken concurrently with the Medical course, and the B.A. degree need not be taken before the final medical examinations, but the Medical degrees are not conferred without the Arts degree. The following courses must be attended:—(1) Lectures—Botany, Zoology, Physics and Practical Physics, Systematic, Descriptive and Applied Anatomy, Chemistry and Practical Chemistry, Histology, Physiology and Practical Physiology, Practice of Medicine, Midwifery, Pathology, Materia Medica and Therapeutics, Medical Jurisprudence and Hygiene, Surgery and Operative Surgery; (2) three courses of nine months' attendance on the Clinical Lectures of Sir Patrick Dun's or other recognised Hospital; (3) Practical Vaccination, one month's instruction; (4) Mental Disease, three months; (5) Practical Midwifery with Clinical Lectures, including not less than 20 personally conducted cases, six months; (6) Ophthalmic Surgery, three months. Three groups of examinations have to be passed. Preliminary Scientific Examination, including Physics and Chemistry, Botany, and Zoology. The Intermediate Medical, Part I. including Anatomy and Physiology, and Part II., including Applied Anatomy and Applied Physiology; and the Final Examination, which is divided into Part I., Materia Medica, Hygiene and Jurisprudence, and Pathology; and Part II., Medicine, including Clinical, Surgery, Midwifery, Gynaecology, Mental Diseases, Operations, and Clinical Ophthalmology. Part I. may be passed in the fourth year and Part II. completed at the end of the fifth year.

Doctor in Medicine.—A Doctor in Medicine must have passed all the qualifying examinations and must be a B.A. of three years' standing. He must also read and discuss a thesis before the Regius Professor of Physic.

Master in Surgery.—A Master in Surgery must be a Bachelor in Surgery of the University of Dublin of not

* The conditions in Ireland have probably interfered with postal arrangements, and from some of the Irish institutions we have been unable to get replies. These institutions are marked with an asterisk.

less than three years' standing, and must produce satisfactory evidence of having been engaged for not less than two years from the date of his registration in the study, or study and practice, of his profession. He must then pass a special examination.

Master in Obstetric Science.—A Master in Obstetric Science must be a Bachelor of two years' standing and produce evidence of having been engaged in the study of Obstetric Medicine and Surgery during two years. He is then required to pass a special examination.

Diploma in Gynaecology and Obstetrics.—A post-graduate diploma is conferred upon registered medical practitioners who take a six months' course at the Rotunda Hospital, a six months' course in Trinity College, and then pass a special examination.

Bachelor in Dental Science and Master in Dental Science.—The regulations under which these degrees are awarded can be obtained by application to the Registrar of the School of Physic.

All Degrees and Courses of Instruction are open to women students.

Clinical instruction.—The hospital facilities for clinical instruction available in Dublin will be described below.

THE NATIONAL UNIVERSITY OF IRELAND.

Matriculation.—All students intending to proceed to the medical degree of the University of Ireland must pass a matriculation examination, the examination taking place in June and September in Dublin and at certain local centres. All students must pass in five subjects (three of which must be Irish, English, and mathematics). All students must pass in Irish except students not born in Ireland, and other students whose home residence shall have been outside Ireland during the three years immediately preceding their matriculation; but all such students will be expected to attend a course of instruction in Irish Literature and History prior to obtaining any degree in the University. The following are the subjects for examination:—1. Irish. 2. Latin or Greek. 3. French, German, Italian, Spanish, Portuguese, Welsh, or any other modern language approved by the Senate. 4. English. 5. Mathematics. 6. Latin, Greek, French, German, Welsh, Spanish, Italian, Portuguese, or any other modern language approved by the Senate. History and Geography (*as a composite subject*), Natural Philosophy, or Physics as an alternative, Chemistry, Botany, and for women candidates only, Physiology and Hygiene. Candidates who under the regulations are exempted from the necessity of presenting Irish as one of their subjects may present as their fifth subject either a second language or a second science subject. Students entering for degrees in Medicine or Dentistry, if already registered by the General Medical Council, may be accepted as matriculated students of the Faculty of Medicine on passing the matriculation examination in any faculty of the University.

The medical degrees granted are:—

M.B., B.Ch., and B.A.O.; and M.D., M.Ch., and M.A.O.—Printed forms of application for admission to any medical examination may be had from "The Registrar, The National University of Ireland, Dublin."

The Constituent Colleges of the National University of Ireland at which the full curriculum for medical degrees can be obtained are University College, Dublin; University College, Cork; and University College, Galway.

UNIVERSITY COLLEGE, DUBLIN.—The University and the College were created by the Irish University Act, 1908, and by Charters issued in December, 1908. Former students of the Cecilia-street School of Medicine who graduated in the Royal University may become graduate members of the new College. The constitution of the College, like that of the Constituent Colleges of Cork and Galway, provides for a governing body, an academic council consisting of professors and co-opted lecturers, a body of graduate members, and a body of student members matriculated in the University. The first professors and lecturers were appointed by the Dublin Commissioners Irish Universities Act, 1908.

Matriculation.—Almost all the students of the College are matriculated students of the National University of Ireland.

University Examinations in Medicine.—The First Examination includes Physics, Chemistry, Botany, and Zoology. The examination may be taken in two parts: Part I., Physics and Chemistry; Part II., Botany and Zoology. Honours may be obtained only when both parts are taken as one examination. The Second Examination includes Anatomy and Physiology. Both must be passed at the same time. The Third Examination includes Pathology, Medical Jurisprudence and Hygiene, and Materia Medica.

Degrees of M.B., B.Ch., and B.A.O.—The Examination in Medicine, Midwifery, Surgery, and Ophthalmology includes both the theoretical and the clinical branches. No student can enter for the M.B., B.Ch., or B.A.O. until the end of the fifth year when the curriculum has been completed. The course of study is as follows:—First year.—Winter: Anatomy and Practical Anatomy (required for the Second Examination), Chemistry, Practical Chemistry, and Experimental Physics (with Laboratory Course). Summer: Zoology, Practical Zoology, Botany, and Practical Botany. Second year.—Winter: Anatomy, Practical Anatomy, Physiology, and Practical Physiology (physical and chemical). Summer: Anatomy, Practical Anatomy, Physiology, and Practical Histology. Third year.—Winter: Pathology, Surgery or Medicine, Hygiene, Medical Jurisprudence, and Practical Pharmacy. Summer: Materia Medica and Therapeutics, and Practical Pathology. Candidates are also required to attend a General Hospital for nine months (winter and summer). Fourth year, or fourth and fifth years.—Winter: Medicine or Surgery (the subject to be that not taken in the third year), and Midwifery and Gynaecology. Summer: Operative Surgery, Applied Anatomy, and Ophthalmology and Otology. Candidates are also required to attend a General Hospital for nine months (winter and summer), and to take instruction in Vaccination, and three months Fever Hospital. Fifth year.—If the Academic (Collegiate) Courses are taken as above, the Courses of the fifth year will be the following: Hospital Attendance, General Hospital, nine months; Clinical Ophthalmology and Otology, three months; Practical Midwifery and Gynaecology, six months; Mental Diseases, to be attended at a Lunatic Asylum, three months. (*Note.*—Practical Midwifery and Gynaecology may be taken in the fourth year after the Systematic Course of Midwifery, but it must not be taken concurrently with the period of attendance at Fever Hospital.) The degree of M.D. may be obtained either by examination or on published work.

Fees.—The fees for Courses may be obtained on application to the Registrar for the College publications.

Information concerning these, and the numerous scholarships and exhibitions of the College can be obtained from the Dean of the Faculty, Professor E. P. McLoughlin.

UNIVERSITY COLLEGE, CORK: THE SCHOOL OF MEDICINE.

—The building is provided with a very large, well-ventilated dissecting room supplied with electric light, with physiological, toxicological, pathological, and pharmaceutical laboratories, materia medica, anatomical and pathological museums, as well as a collection of surgical and obstetrical instruments and appliances. There are well-appointed physical, chemical, and biological laboratories, and a large natural history museum in the adjoining building, and part of the College ground is laid out as a botanical garden. The plant houses are well filled with plants and are open to the students in the class of Botany. The Library contains about 70,000 volumes and is open daily during term time to students. The Medical Museum occupies a large room erected at the northern end of the medical buildings. There are Students' Clubs for men and women students of the College and various athletic clubs, the last of these holding a public meeting once in each year in the Mardyke grounds.

All students who have been admitted as matriculated students are required to attend before the President and sign the Roll of Matriculated Students. Students who are candidates for degrees in the National University of Ireland must have passed the Matriculation Examination of that University or other recognised examination, and medical students must have passed a preliminary examination

recognised by the General Medical Council. For information as to the conditions and courses of the Matriculation Examination application may be made to the Registrar, National University, Dublin.

Admission of Medical Students.—Students in the Faculty of Medicine who have passed the First Professional Examination of the Conjoint Examinations of the Royal College of Physicians and the Royal College of Surgeons in Ireland, or of the Royal College of Physicians and Royal College of Surgeons of Edinburgh and the Faculty of Physicians and Surgeons of Glasgow, or of the Royal College of Physicians, London, and Royal College of Surgeons, England, may be admitted to the rank of second-year students on making application to the Council and submitting a certificate of having passed the examination. Similarly, students who have passed the Second Professional Examination of the same Colleges may be admitted to the rank of third-year students; and those who have passed the Third Professional Examination of the Dublin Colleges, or of the Edinburgh Colleges and Glasgow Faculties, may be admitted to the rank of fourth-year students.

Residence of Students.—There is no accommodation for the residence of students within the College, but students not living at home, or with relatives or friends, sanctioned by their parents or guardians, are required to live in a hostel or in recognised lodgings, a list of which can be obtained from the Secretary. All students are required to register their addresses each session in the book kept for that purpose in the hall porter's office, and to notify immediately to the Registrar any change of address during the session. The Honan Hostel, adjoining the College, is equipped by private endowment. A number of sets of rooms, together with recreation and common rooms, are provided for lay students who may desire to live there. For full particulars apply to the Warden. The Ursuline Convent, Blackrock, has a house of residence, quite separate from their Secondary School, for Catholic women students.

Clinical Instruction.—Students may attend the South Infirmary, Cork North Charitable Infirmary, the Mercy Hospital, the Cork District Lunatic Asylum, the Victoria Hospital for Diseases of Women and Children, the County Lying-in Hospital, the Cork Maternity, the Cork Fever Hospital, the Cork District Hospital, and the Cork Ear, Eye, and Throat Hospital.

Complete information with regard to class fees, scholarships, and prizes can be obtained from the Dean of the Medical Faculty, Professor A. E. Moore.

South Infirmary and County of Cork General Hospital (100 beds).—Clinical instruction is given daily in the wards. Special instruction on Diseases of Women and Children will be given in the special wards for such cases. Fee for nine months, £12 12s.; for six months, £8 8s.; for three months, £4 4s. Two resident pupils will be appointed by competitive examination. Honorary Secretary: Dr. N. I. Townsend.

Cork North Charitable Infirmary and County and City of Cork General Hospital (112 beds).—Clinical instruction is given daily in the wards by the physicians and surgeons. Special instruction is given to Junior Students on two days weekly. Fee for perpetual ticket, £22 1s.; for 12 or nine months, £9 9s.; for six months, £5 5s.; and for three months, £3 3s. Two resident pupils are appointed quarterly by the medical staff. All resident pupils are required to be registered pupils of the hospital. There is a special department for treatment of the eye, ear, throat, and nose, under the charge of Mr. J. Bowring Horgan, and a special dental department. Honorary Secretary: Dr. R. B. Dalton. The Hospital contains a fully equipped Pathological Department, and a large and extensive X Ray Department has recently been added.

Mercy Hospital.—This hospital contains 130 beds for medical and surgical cases. There is also a daily extern for medical and surgical cases, as well as for diseases of the eye, ear, and throat. Extern medical attendances for 1919, 5933; surgical attendances, 2940; eye, ear, nose, and throat attendances, 8170; intern patients, 1526. Major operations, 798; minor operations, 743. Minor accidents, 3010. Total extern free attendances, 36,105. Two resident students. Honorary Secretary to the Staff: Dr. D. J. O'Connor.

Cork District Lunatic Asylum.*—Psychological Medicine: A course of Clinical Lectures on Mental Disease and Allied Neuroses will be delivered in the Cork District Lunatic Asylum on Mondays and Thursdays, commencing the first Thursday in May, by the Resident Medical Superintendent. All students wishing to enter for the course are expected to attend at the Asylum at 4 P.M. on that day. All information may be had at the Asylum from the resident medical superintendent.

Victoria Hospital (Incorporated)* (Cork).—There are 75 beds. Clinical instruction on Diseases Peculiar to Children is given. The extern department is open daily at 9.30.

County and City of Cork Lying-in Hospital (Erinville, Western-road; founded 1798).—This hospital contains 22 beds, an Extern Midwifery Department, Gynaecological Department, Extern Department for Women, and Child Welfare Centre. Fee for six months' attendance, including clinical lectures, £5 5s. For further particulars apply to Lucy E. Smith, M.D., secretary to staff.

Cork Maternity* (Batchelor's Quay).—Three resident pupils are taken into the Maternity. Poor women are attended at their own homes. Clinical lectures are delivered during the session. There is an extern department for the treatment of women's and children's diseases. Fee for attendance at clinical lectures and certificate, £3 3s. Honorary secretary to staff, Dr. Henry Corby.

Cork Fever Hospital.*—Upwards of 500 cases of various forms of fever and zymotic disease are treated yearly in this hospital. The Resident Medical Officer gives instruction in Practical Pharmacy, a certificate of which is necessary for the National University and Colleges of Physicians and Surgeons of Edinburgh.

Cork District Hospital* (Douglas-road; 1200 beds).—This hospital includes special buildings for fever and other infectious diseases (100 beds); for children's diseases (100 beds); and a Lock hospital, the only one in the South of Ireland (80 beds). It affords an extensive field for the study of all classes of diseases, acute and chronic, including special departments for gynaecology and diseases of the skin and nervous system. The physicians and surgeons visit the hospitals every morning at 10 o'clock. Lectures and clinical instruction are given daily in the wards by the physicians and surgeons. Further particulars may be obtained from Dr. W. E. Ashley Cummins, 17, St. Patrick's-place, honorary secretary, medical staff.

Cork Eye, Ear, and Throat Hospital (Western-road).—This hospital is open to students attending the University College and others. Certificates of attendance for three or six months can be obtained. The hospital contains 35 beds. Over 4000 cases are treated during the year. A course of Lectures on Ophthalmic Surgery is delivered during the session. For further information apply to Dr. Arthur Sandford, 13, St. Patrick's-place, Cork.

UNIVERSITY COLLEGE, GALWAY: SCHOOL OF MEDICINE.

—The College contains a well-lighted and ventilated dissecting-room and an anatomical lecture theatre; physiological, pathological, pharmaceutical, chemical, and physical laboratories; anatomical, pathological, gynaecological, and materia medica museums; as well as large natural history and geological museums and an extensive library in which students can read and from which they can borrow books. There are 12 Entrance Scholarships, value £25 each, for which Medical Students compete with other Students on the Entrance Course. In the Second, Third, and Fourth Years three Scholarships in each year, value £25 each, are reserved for Medical Students. Exhibitions of £10 and £5 are awarded on results of 1st, 2nd, 3rd, and Degree Examinations in Medicine. H. H. Stewart Scholarships (£10 a year for three years) are awarded by the University in Anatomy and Physiology at Second Medical Examination amongst Students of the three constituent Colleges. Travelling Studentships (£200 a year for two years) are offered by the University for competition amongst Medical Graduates of the three Colleges of not more than two years' standing. Women students are eligible for all College and University Degrees, Distinctions, and Prizes. There are extensive grounds, a portion of which is occupied by a Botanic Garden and a portion is at the disposal of the College Athletic Union. There are several student societies

in the College, including a Biological Society. There are abundant facilities for research and Post-graduate work in the Chemistry, Physiology, and Pathology departments. There are ample facilities for Women Students. Further information can be obtained from the Registrar of the College.

Clinical Instruction is given in the Galway Hospital and in the Galway Union and Fever Hospitals, containing on an average 200 patients.

*Galway County Hospital** (62 beds).—Founded by Act of Parliament.

Galway Union and Fever Hospitals (150 beds).—Clinical instruction is given in these hospitals to the Medical Students of University College, Galway. The regulations for Scholarships tenable in the College, and the regulations for degrees and for courses can be obtained from Messrs. O'Gorman and Co., Galway.

QUEEN'S UNIVERSITY OF BELFAST.

There are six degrees in the Faculty of Medicine of the University—viz., Bachelor of Medicine (M.B.), Bachelor of Surgery (B.Ch.), Bachelor of Obstetrics (B.A.O.), Doctor of Medicine (M.D.), Master of Surgery (M.Ch.), and Master of Obstetrics (M.A.O.). The University also grants a Diploma in Public Health, particulars of which will be found in the University Calendar. The degrees of M.B., B.Ch., and B.A.O. are the primary degrees in the Faculty of Medicine, and are conferred at the same time and after the same course of study. No student is admitted to the final examination for these degrees until he has shown: (1) that he is a matriculated student of the University; (2) that he has completed the prescribed course of study in the Faculty of Medicine extending over a period of not less than five academic years from the date of his registration as a student of Medicine by the General Council of Medical Education and Registration of the United Kingdom; (3) that he has passed the several examinations prescribed; (4) that he has attended in the University during three academic years at least the courses of study prescribed for such degrees (the Senate may accept, for not more than two academic years of the required five, courses of study pursued in any other University or School of Medicine approved by the Senate); and (5) that he has attained the age of 21 years. Every candidate for admission as a matriculated student of the University shall pass such Matriculation Examination or fulfil such other test of fitness as may be prescribed by the Senate, which may prescribe the conditions under which students who have passed the Matriculation or Entrance Examination of any other University or College approved for that purpose (or who have fulfilled such other test of fitness as may be prescribed) may be exempted from passing the Matriculation Examination of the University. For information as to Scholarships and Prizes inquiry should be made of the Secretary of the University.

Primary Degrees of M.B., B.Ch., B.A.O.—All candidates for these degrees must satisfy the examiners in the subjects of four examinations known as the First, Second, Third, and Fourth Medical Examinations respectively.

The First Medical Examination.—The subjects of this examination are Chemistry (Inorganic and Organic), Experimental Physics, Botany and Zoology. The examination will be divided into two parts which may be taken separately: I., Chemistry and Physics; II., Botany and Zoology.

The Second Medical Examination.—The subjects are Anatomy and Practical Anatomy, Physiology and Practical Physiology. Candidates who have previously passed the First Medical Examination may present themselves for this examination at the close of their second year.

The Third Medical Examination.—The subjects are: (1) Pathology and Practical Pathology; (2) Materia Medica, Pharmacology and Therapeutics; (3) Medical Jurisprudence; (4) Hygiene. Candidates who have previously passed the Second Medical Examination may present themselves for this examination at the close of the third year. Attendance on a course in any subject of the Third Medical Examination shall not entitle a student to a certificate of attendance unless he has previously passed in all the subjects of the First Medical Examination.

The Fourth Medical Examination.—The subjects are: (1) Medicine; (2) Surgery; (3) Midwifery; (4) Ophthalmology and Otology. This examination may be taken in two

parts: I., Systematic; II., Clinical, Practical and Oral. Candidates who have previously passed the Third Examination may present themselves for Part I. of the Fourth Examination at the close of the fourth year, provided that they have fulfilled the necessary requirements as to attendance, &c., on the courses of instruction in the subjects of examination. Candidates who have passed Part I. of this examination may present themselves for Part II. at the close of the fifth year, provided that they have fulfilled the necessary requirements as to hospital attendance on the various clinical courses in the subjects of examination. Parts I. and II. may be taken together at the close of the fifth year. Attendance on a course in any subject of the Fourth Medical Examination shall not entitle a student to a certificate of attendance unless he has previously passed in all the subjects of the Second Medical Examination.

Degrees of M.D., M.Ch., and M.A.O.—These degrees are not conferred until the expiration of at least three academic years, or in the case of graduates of the University in Arts or Science of at least two academic years, after admission to the primary degrees in the Faculty of Medicine. Every candidate must show that in the interval he has pursued such courses of study, or been engaged in such practical work as may be prescribed. These degrees may be conferred by the Senate either (a) after an examination, which includes written, oral, clinical, and practical examinations; or (b) on the submission of a thesis or other evidence of original study or research, to be approved by the Faculty of Medicine after an oral or other examination of the candidate on the subject thereof.

The Medical School.—The Donald Currie Chemical Buildings contain a lecture theatre, a preparation room, a chemical museum, a large class-room for elementary practical chemistry, laboratories for qualitative and quantitative analysis, rooms for water and gas analysis, dark room for photographic purposes and balance room, provided with all modern appliances. The Anatomical Department contains a large and well-lighted dissecting-room, a lecture-room, a professor's and demonstrator's room, a bone-room, and a laboratory for microscopic and photographic work. The Medical Museum is in the same building. The Jaffé Laboratories for Physiology comprise a lecture theatre, laboratories for practical work in chemical physiology, histology, and experimental physiology, and in addition small private research rooms, including balance, galvanometer, and centrifuge rooms. The Musgrave Pathological Laboratory.—In this department opportunity is afforded for research in pathology and bacteriology. The department is in touch with most of the hospitals in Belfast, and there is an ample supply of material for investigation by graduates in morbid histology, clinical pathology, and the bacteriology of infectious diseases. A course in pathology or bacteriology is given to graduates, and members of this class have an opportunity of seeing the methods employed in the various investigations carried out in the department for the Public Health Committee of the corporation in connexion with water-supply, sewage disposal, meat- and milk-supply, the diagnosis of cases of infectious diseases, &c. The certificate issued to members of the class in bacteriology qualifies for the D.P.H. degree. The Pharmaceutical Laboratory is fitted and equipped for the work of practically instructing students in the compounding and dispensing of medicines.

Clinical instruction.—The following institutions are recognised by the University as affording proper opportunities for clinical instruction: the Royal Victoria Hospital, the Mater Infirmorum Hospital, the Union Hospitals, the Belfast Hospital for Sick Children, the Belfast Maternity, the Ulster Hospital for Women and Children, the Ulster Eye, Ear, and Throat Hospital, the Belfast Ophthalmic Hospital, the Purdysburn Fever Hospital, and the Belfast District Lunatic Asylum.

Royal Victoria Hospital (300 beds).—Women students are now admitted as resident medical pupils the same as men.

Mater Infirmorum Hospital (200 beds).—Honorary Secretary Medical Staff: Mr. J. B. Moore.

Belfast Union Infirmary and Hospital (1600 beds).—Clinical courses are given biennially, and course for D.P.H. in Hospital. Intern. Venereal Clinic in Infirmary under

Corporation scheme. Particulars may be obtained on application, as to classes, to Dr. McLiesh.

Hospital for Sick Children, Queen-street (52 beds).—Honorary Secretary, Medical Staff: John McCaw, M.D.

Incorporated Belfast Maternity Hospital, Townsend-street (32 beds). New Pre-Natal Clinics are being arranged in addition to the present ward clinics.

Ulster Hospital for Children and Women (44 beds).

*Benn Ulster Eye, Ear, and Throat Hospital** (30 beds).

Belfast Ophthalmic Hospital, Great Victoria-street (30 beds).—Practical demonstrations by the staff and occasional clinical lectures in the subjects of Ophthalmology, Otolaryngology, and Laryngology. Clinical instruction is given daily. Fee for three months £2 2s.

Belfast Fever Hospitals.—City Fever Hospital, Purdysburn (330 beds); Union Fever Hospital (200 beds). Clinical Classes are held during the winter and summer sessions. Post-Graduate (D.P.H.) Classes are also held.

Belfast District Lunatic Asylum (1000 beds).

IRISH MEDICAL CORPORATIONS GRANTING DIPLOMAS.

ROYAL COLLEGE OF PHYSICIANS OF IRELAND.

The College issues its Licences in Medicine and in Midwifery to practitioners whose names appear on the Medical Register of the United Kingdom.

The Licence in Medicine.—The subjects of examination are: Practice of Medicine, Clinical Medicine, Pathology, Medical Jurisprudence, Midwifery, Hygiene, and Therapeutics.

The Licence in Midwifery.—Candidates must produce certificates of registration. A registered medical practitioner of five years' standing may be exempted from the examination by printed questions.

The Membership.—Examinations for Membership are held in February, June, and November. The fee for the examination is £21 to Licentiates of the College, or £36 15s. to non-Licentiates. Further particulars can be obtained from the Registrar of the Royal College of Physicians of Ireland, Kildare-street, Dublin.

The Fellowship.—Fellows are elected by ballot. Applicants must have been a Member of the College for at least one year and must have attained the age of 27 years. There is a fee of £35 in addition to a stamp duty of £25.

ROYAL COLLEGE OF SURGEONS IN IRELAND.

The Licence in Surgery.—A candidate whose name is entered either on the Medical Register for the United Kingdom, the Colonial Medical Register, or the Foreign Medical Register of the year in which he presents himself for examination, and who satisfies the Council that he has passed through a course of study and Examinations equivalent to those required by the Regulations of the Conjoint Board of the Royal College of Physicians of Ireland and the Royal College of Surgeons in Ireland, preceded by the passing of an Examination in Arts recognised by the General Medical Council, may, at the discretion of the Council, be admitted to the Examination.

Candidates are examined in Surgery, Clinical Surgery, Operative Surgery on the subject, Surgical Appliances, and Ophthalmic Surgery.

Diploma in Midwifery.—A diploma in Midwifery is granted after examination to persons possessing a registrable qualification.

Fellowship Examinations.—Candidates for the Fellowship shall make application to the President and Council to be admitted to examination. They are required to pass two examinations—Primary and Final. Candidates may present themselves for the Final Examination immediately after passing the Primary part, provided they have complied with the necessary regulations. The subjects for the Primary Examination are (a) Anatomy, including Dissections; and (b) Physiology and Histology. The subjects for the Final Examination are Surgery, including Surgical Anatomy and

Pathology. For admission to the Final Examination the candidate must have passed the Primary Examination, and must be a Licentiate or Graduate in Surgery of a university or licensing body recognised by the General Medical Council; all such candidates must not be less than 25 years of age.

Further particulars as to fees and conditions of examination can be obtained from the Registrar of the College, Stephen's-green, West Dublin.

ROYAL COLLEGE OF PHYSICIANS OF IRELAND AND ROYAL COLLEGE OF SURGEONS IN IRELAND.

Every candidate for the Conjoint Examinations of the Colleges shall produce evidence of having before entering on medical studies passed a Preliminary Examination in general education recognised by the Royal Colleges. Each candidate before receiving his diplomas must produce a registrar's certificate or other satisfactory evidence that he has attained the age of 21 years.

Preliminary Examination.—The subjects for examination are identical with those prescribed for the Preliminary Examination by the General Council of Medical Education and Registration.

Professional Examinations.—Every candidate must pass four Professional Examinations—at the end of the first, second, third, and fifth years respectively of his professional studies. No candidate shall be admitted to the Final or Qualifying Examination within three months of his rejection at the Final or Qualifying Examination by any other licensing body.

First Professional Examination.—Every candidate is required, before admission to the First Professional Examination, to produce evidence—(1) of having passed in the subjects of the Preliminary Examination; and (2) of having attended a course of—(a) lectures on Theoretical Chemistry, six months; (b) Practical Chemistry, three months; (c) Biology, three months; and (d) Physics.

The subjects of the First Professional Examination are the following:—1. (a) Chemistry; (b) Physics. 2. Biology. The fee for this examination is £15 15s.

Second Professional Examination.—Candidates are not admissible to this examination till they have passed in the subjects of the First Professional Examination, and they must produce evidence of having attended (a) anatomical dissections, six months; and Lectures on (b) Anatomy, six months; (c) Physiology, six months; (d) Practical Physiology and Histology, three months.

The subjects of the Second Professional Examination are the following:—(1) Anatomy; and (2) Physiology and Histology. The fee for this examination is £10 10s.

Third Professional Examination.—Every candidate is required, before admission to the Third Professional Examination, to produce evidence of having passed the Second Professional Examination, and certificates of having attended courses of instruction in (a) the practice of a medico-chirurgical hospital for nine months; (b) Pathology—(1) Systematic, (2) Practical, three months each; (c) Materia Medica, Pharmacy, and Therapeutics, three months; (d) Forensic Medicine and Public Health, three months. The subjects for the Third Professional Examination are the following:—(1) Pathology; (2) Materia Medica, Pharmacy, and Therapeutics; (3) Public Health and Forensic Medicine. The fee for this examination is £9 9s. Clinical instruction in Ophthalmic and Aural Surgery, three months. The examination in Ophthalmic and Aural Surgery may be taken immediately after passing the Third Professional Examination.

Final Professional Examination.—Before admission to the Final Examination candidates must have passed the Third Professional Examination and produced evidence of having attended in Division I. the practice of a medico-chirurgical hospital for two periods of nine months each (unless such evidence has been previously produced for admission in Division II.); the practice of a recognised fever hospital or the fever wards of a recognised clinical hospital, three months; clinical instruction in Mental Diseases, one month (12 attendances); lectures on Medicine, six months at a recognised medical school; of having performed the duties of medical clinical clerk in a recognised hospital for three months; of having attended a

course of instruction in post-mortem examinations and demonstrations during one session. In Division II. of having attended the practice of a medico-chirurgical hospital for two periods of nine months each (unless such evidence has been previously produced for admission to Division I.); lectures on Surgery, six months at a recognised medical school; instruction in Operative Surgery, three months at a recognised medical school; of having performed the duties of surgical dresser in a recognised hospital for three months; of having attended a course of instruction in the practical administration of general anaesthetics. In Division III. of having attended a midwifery hospital or maternity and having been present at 20 labours, six months; instruction on vaccination, six attendances to be certified by a public vaccinator; lectures on midwifery (including diseases peculiar to women and to new-born children), six months at a recognised medical school. Candidates are recommended to present themselves in all the subjects of the Final Examination at one time, but a candidate at or after the end of the fourth year may present himself in any one of the Divisions I., II., or III., provided he has completed his curriculum as far as concerns the division in which he presents himself. The examination in at least one of the divisions must be deferred till the end of the fifth year.

The subjects of the Final Examination are: (1) Medicine, including Fevers, Mental Diseases, and Diseases of Children; (2) Surgery, Operative; and (3) Midwifery and Gynaecology, Vaccination, and Diseases of New-born Children. The fee is £6 6s. Further particulars can be obtained from Alfred Miller, O.B.E., the Secretary of the Committee of Management, Royal College of Surgeons, Stephen's-green, Dublin.

ROYAL COLLEGE OF SURGEONS IN IRELAND (SCHOOLS OF SURGERY).—The schools of surgery are attached by Charter to the Royal College of Surgeons and have existed as a department of the College for over a century. They are carried on within the College buildings and are specially subject to the supervision and control of the Council, who are empowered to appoint and remove the professors and to regulate the methods of teaching pursued. The buildings have been reconstructed, the capacity of the dissecting-room nearly trebled, and special pathological, bacteriological, public health, and pharmaceutical laboratories fitted with the most approved appliances in order that students may have the advantage of the most modern methods of instruction. The entire building is heated by hot-water pipes and lighted throughout by the electric light. Winter Session commences in October; Summer Session in April. Scholarships and Prizes: Carmichael Scholarship, £15; Mayne Scholarship, £8; Stoney Memorial gold medal; Operative Surgery, gold and silver medals; Barker Prize, £26 5s.; H. Macnaughton-Jones gold medal in Obstetrics and Gynaecology; and class prizes and medals. Prospectuses and guide for medical students can be obtained post free on written application to the Registrar, Royal College of Surgeons, Stephen's-green, W., Dublin.

APOTHECARIES' HALL OF IRELAND.*

The Licence of this Hall is granted to students who present certificates of having fully completed the course of study as laid down in the curriculum and who pass the necessary examinations. The diploma of the Apothecaries' Hall of Ireland entitles the holder to be registered as a practitioner in medicine, surgery, and midwifery, with also the privileges of the Apothecary's Licence. There are three professional examinations, the total fees for which amount to 30 guineas. Women are eligible for the diploma.

There are four examinations—primary, intermediate, Parts I. and II., and final. They are held three times a year, in March, June, and December. The primary examination comprises biology, physics, theoretical and practical chemistry (with an examination at the bench). Candidates holding a Pharmaceutical licence are exempt from this subject. Intermediate, Part I., Anatomy and Physiology. Intermediate, Part II., Pathology, Medical Jurisprudence, and Materia Medica and Pharmacy. The intermediate examination comprises anatomy of the whole body (including practical dissections), physiology, practical histology, and materia medica. The final examination comprises medicine, surgery, and midwifery.

Each candidate before receiving his diploma must produce evidence that he has attained the age of 21 years. The details of the course of education required and syllabus of the examinations will be supplied on application to the Registrar at 40, Mary-street, Dublin.

HOSPITALS AFFORDING PRACTICE RECOGNISED BY THE IRISH UNIVERSITIES AND CORPORATIONS.¹

ADELAIDE HOSPITAL, Peter-street, Dublin.*—Fee for nine months' hospital attendance, £12 12s.; six months, £8 8s. Summer, three months, £5 5s. Two resident surgeons are elected yearly and four resident pupils half-yearly. At the termination of the session prizes in Clinical Medicine and Surgery and in Dermatology will be awarded.

Hudson Scholarship.—In addition to the junior prizes the Hudson Scholarship, £30 and a gold medal, as well as a prize of £10, together with a silver medal, will be awarded at the end of the session for proficiency in medicine, surgery, gynaecology, and pathology.

The certificates of attendance are recognised by all the Universities and licensing bodies in the United Kingdom. Further particulars may be obtained from Dr. H. Bewley.

COOMBE LYING-IN HOSPITAL AND GUINNESS DISPENSARY FOR THE TREATMENT OF DISEASES PECULIAR TO WOMEN. Dublin.—This hospital contains nearly 70 beds and consists of two divisions, one of which is devoted to lying-in cases and the other to the treatment of diseases peculiar to women. The practice of this hospital is one of the largest in Ireland. Lectures are delivered, practical instruction given, and gynaecological operations are performed in the theatres daily. There is a general dispensary held daily, at which instruction is given on the Diseases of Women and Children. There is a special afternoon dispensary held by the Master and his assistants, at which practical instruction in gynaecology is given. There is no extra charge for attendance at this dispensary. There is accommodation for intern pupils who enjoy exceptional advantages of acquiring a thorough knowledge of this branch of their profession. Lady medical students can reside in the hospital. The residents' quarters are comfortable. Clinical assistants are appointed from amongst the pupils as vacancies occur. Certificates of attendance at this hospital are accepted by all licensing bodies. Fees: Extern pupils for full course of six months, £8 8s.; three months, £4 4s. Intern pupils, one month, £4 4s.; each consecutive month, £3 3s.; six months, £18 18s.; board and lodging in the hospital, 25s. per week. Lady students, intern, one month, £4 4s.; each consecutive month, £3 3s. Registration fee, in advance, 10s. 6d. Students can enter for attendance at any time, but preference is given to those entering from the first day of the month. Further particulars may be had on application to the Master or the Registrar at the hospital.

SIR PATRICK DUN'S HOSPITAL, Grand Canal-street, Dublin.—Classes both in Medicine and Surgery are held each morning from 9 o'clock from Oct. 1st till the end of June. Special classes for junior students will be held in the wards during the months of October, November, and December. A Resident Surgeon, with salary, is appointed annually. Six Resident Pupils are appointed each half-year. Six Surgical Dressers and six Clinical Clerks are appointed each month. There are facilities for women students.

Prizes and Medals.—Clinical medals and prizes amounting to about £15 each will be awarded in Medicine and in Surgery respectively in accordance with the will of the late Rev. Samuel Haughton, M.D., S.F.T.C.D. Candidates who fail to obtain these medals and prizes will be awarded special certificates in Medicine and in Surgery provided they show sufficient merit.

Fees.—Winter and summer session, £12 12s.; winter session (six months), £8 8s.; and summer session (three months), £5 5s. Special certificate in anaesthetics, £1 1s. The practice of this hospital is open to all students, and the certificates are recognised by Dublin University, the

¹ This list of the institutions recognised by the Conjoint Board of Ireland is supplemented in the regulations of the Colleges by those hospitals mentioned as recognised institutions in Scotland and England. The recognised facilities for clinical instruction in Belfast, Cork, and Galway have been described in connexion with the Belfast and National Universities.

National University and Royal Colleges of Surgeons of England, Ireland, and Scotland.

Further information will be supplied by the Hon. Secretary to the Medical Board.

JERVIS-STREET HOSPITAL, Dublin.—Founded 1718; rebuilt 1886. 130 beds. A new out-patient department has been completed and contains all modern requirements. Secretary: Mr. Kieran O'Dea.

MATER MISERICORDIÆ HOSPITAL, Dublin.—This hospital, the largest in Ireland, containing 382 beds, is open at all hours for the reception of accidents and urgent cases. Clinical instruction will be given by the Physicians and Surgeons at 9 A.M. daily. Ophthalmic Surgery will be taught in the Special Wards and in the Dispensary. Surgical Operations will be performed daily. Connected with the hospital are extensive Dispensaries, which afford valuable opportunities for the study of general Medical and Surgical Diseases, and Accidents. Instruction will be given on Pathology and Bacteriology. Three House Physicians, six House Surgeons, and 16 resident pupils will be elected annually. Dressers and Clinical Clerks will also be appointed, and certificates will be given to those who perform their duties to the satisfaction of the staff. Leonard Prizes will be offered for competition annually. For further particulars see prospectus. Certificates of attendance upon this hospital are recognised by all the Universities and licensing bodies in the United Kingdom. There is a Private Hospital for the reception of Medical and Surgical cases; also a Training School and a Home for Trained Nurses in connexion with the Hospital.

Terms of attendance.—Nine months, £12 12s.; six winter months, £8 8s.; three summer months, £5 5s. Entries can be made with any of the physicians or surgeons, or with the Registrar, Dr. Martin Dempsey, 35, Merrion-square. A prospectus containing in detail the arrangements for Clinical Instruction, Prizes, &c., may be obtained from the Secretary, Medical Board, Mr. H. Barniville, 9, Merrion-square.

MEATH HOSPITAL AND COUNTY DUBLIN INFIRMARY.—This hospital was founded in 1753 and now contains 166 beds available for clinical teaching. A building containing 40 beds for the isolated treatment of fevers is attached to the hospital. The certificates of this hospital are recognised by all the universities and licensing bodies of the United Kingdom. Medical Clinical Clerks and Surgical Resident Pupils and Dressers are appointed every three months, and House Surgeons and Clinical Assistants are elected annually. A prospectus giving the complete arrangements for the coming session may be obtained from the Honorary Treasurer of the Medical Board, Sir L. H. Ormsby, 92, Merrion-square, Dublin.

MERCER'S HOSPITAL.—This hospital, founded in 1734, is situated in the centre of Dublin, in the immediate vicinity of the Schools of Surgery of the Royal College of Surgeons, the Catholic University School of Medicine, and within five minutes' walk of Trinity College. It contains 120 beds for medical and surgical cases, and arrangements have been made with the medical officers of Cork-street Fever Hospital whereby all students of this hospital are entitled to attend the clinical instruction of that institution and become eligible for the posts of Resident Pupil, &c. There is a large dispensary for out-patients. Students of the hospital are permitted to attend the gynaecological department, where they receive practical instruction. There are special wards for the treatment and study of children's diseases. During the past few years the hospital has undergone extensive alterations in order to bring it up to modern requirements.

Appointments.—A House Surgeon is appointed annually. There are Six Resident Pupils, and Clinical Clerks and Dressers are appointed from amongst the most deserving members of the class. Women students are admitted.

Fees.—Winter, six months, £8 8s.; Summer, three months, £5 5s.; nine months, £12 12s.

For further particulars apply to Dr. Bethel Solomons, Hon. Sec., Medical Board, 42, Fitzwilliam-square, Dublin.

NATIONAL MATERNITY HOSPITAL, Holles-street, Dublin.—Established 1894. The Hospital consists of an Intern and Extern Maternity, and a Dispensary for the treatment of Diseases of Women and Children. About 1035 cases are admitted and over 300 operations are performed annually. Every facility is given for the carrying out of practical work.

Post-graduate and special courses are arranged for at any time. Certificates of attendance at this hospital are recognised by all the licensing bodies. Terms (three months' course) 6 guineas. Board 30s. per week. Medical men can take out Post-graduate courses by paying a fee of £3 3s. for the first month. If he wishes to remain a second month the fee is £2 2s. Clinical Lectures are given daily and Oral Lectures four times per week. Further particulars can be obtained from the Masters: Sir Andrew Horne, 94, Merrion-square, Dublin; Dr. Reginald J. White, 23, Merrion-square, Dublin; or from the Secretary, Holles-street, Dublin.

RICHMOND, WHITWORTH, AND HARDWICKE HOSPITALS (HOUSE OF INDUSTRY HOSPITALS), Dublin.—These hospitals contain 330 beds—130 for Surgical cases, 80 for Medical cases, 78 for Fever and other Epidemic Diseases, and an Auxiliary Wing of 42 beds. Their pecuniary position has been recently very precarious. A Resident Physician and a Resident Surgeon are appointed each half year and are paid for their services. 12 Resident Clinical Clerks are appointed each quarter and provided with furnished apartments, fuel, &c. These appointments are open not only to advanced Students but also to those who are qualified in Medicine and Surgery. The Dressers are selected from among the best qualified of the pupils without the payment of any additional fee. Women students are eligible for election as residents and special apartments are reserved for their use. For prospectuses apply to Mr. Adams McConnell, F.R.C.S.I., Hon. Secretary, 69, Fitzwilliam-square, Dublin.

ROTUNDA HOSPITAL, Dublin.—This institution is the largest combined gynaecological and maternity hospital in the British Empire. Over 4000 confinements attended annually. Students can take out their necessary gynaecological and midwifery practical courses. Appointments open to qualified practitioners as Assistant to the Master and Extern Assistants. Women students can reside in the hospital on terms similar to those for men. Fees for intern students: One month £6 6s., two months, £9 9s., three months £12 12s., six months £21, single months other than the first £4 4s. For further particulars apply to the Master.

ROYAL CITY OF DUBLIN HOSPITAL.*—Founded 1832; enlarged 1851; rebuilt 1893. 150 beds. There is a special wing for the treatment of fevers and contagious diseases founded by the late Mr. Drummond. Secretary: Mr. Edw. B. Armstrong.

ROYAL VICTORIA EYE AND EAR HOSPITAL, Dublin.—Established 1844. Incorporated 1897. 102 beds. In-patients, 1610; out-patients, 9386. Two house surgeons for Eye and one for Ear appointed annually.

DR. STEEVENS' HOSPITAL, Dublin.—Established 1720. 250 beds. Patients, 12,834. Secretary: Mr. R. J. Ogden.

ST. VINCENT'S HOSPITAL AND DISPENSARY, Dublin.*—Established 1834. 200 beds.

WE take this opportunity of thanking the Deans and Secretaries of the various institutions for their kind coöperation in enabling us to bring the information contained in our Students' Number up to date.

THE CHARTERED SOCIETY OF MASSAGE AND MEDICAL GYMNASTICS.—Incorporated by Royal Charter, June 9th, 1920, and amalgamating the Incorporated Society of Trained Masseuses and the Institute of Massage and Medical Gymnastics. The Chartered Society has been formed for the purpose of affording protection to the profession of massage and to its registered members: by improving the training and status of masseuses and masseurs, by providing and supervising independent examinations, by setting up registers of persons qualified to practice, by arranging post-graduate courses, lectures, and conferences, by supplying work for members (under registry regulations), and by working in all ways for the advancement and general welfare of the profession. Registration with the Chartered Society is open to all certificate holders of the Incorporated Society and of the Institute. Test examinations will be set up for the benefit of masseuses and masseurs of experience, holding certificates other than the above-mentioned, who wish to register with the Chartered Society. Forms of application for registration and all information can be obtained from the offices of the Society, 157, Great Portland-street, W.1.

THE LANCET.

LONDON: SATURDAY, AUGUST 28, 1920.

Medical Training and the Clinical Units.

THE educational year opens in circumstances uncertain and involved for all the nations that on earth do dwell, and as it is the grand privilege of medicine to possess and cultivate universal inter-relations it follows that every moral and material trouble which falls upon man is reflected in medicine, and reflected as much in the training of the students as in the conduct of general practice and the progress of scientific research. All the training of the medical student during the next year must be carried on under the grave disabilities that the curriculum becomes steadily more costly, that those who pay for it possess for the most part less resources from which to find the money, and that the institutions, hospitals, schools, laboratories, and special clinics alike are suffering from the straitness of the times. No students can be so directly affected by the post-war conditions as those who desire to follow medicine. It may therefore be regarded as a triumph for our profession that never, so far as we know, have so many young persons felt an urgent call upon them to enter the ranks of medicine; and in this country the triumph is shared by the new Ministry of Health, for the readiness of the recruiting must indicate belief in the soundness of the promised reorganisation of the medical services of the country. Our young men and women are thinking, and their parents and guardians are sharing the thought, that the profession of medicine in the future, though sorely tried in the present, will emerge not only as a career whose nobility has been insisted upon to nausea, but as one whose orderly scheme will promote domestic, social, and international amelioration in the interests of the whole civilised world.

In the Students' Number we set out, as usual, the patterns of medical training in the three divisions of the country, indicating in this way what has to be done by the aspirant before he can be admitted to our ranks; and under various special headings the attempt is made to show how varied are the openings which lie ahead and how genuine are the prospects of a successful as well as a useful life which attend the earnest student. A particular development in medical education to which we propose to call attention now is the establishment of clinical units in connexion with the great teaching hospitals, the immediate reference being to what has been happening at certain of the London medical schools. We have frequently referred to the gradual evolution of special departments of the medical curriculum, and this year a distinct step forward can be chronicled. For the institution of clinical units illustrates the development of the medical student from the apprentice who learned by watching his master into the undergraduate taught by university professors. This development has long remained arrested at a certain point, but if the dates of reform have lingered it must be remembered that under the older plans

this country was an acknowledged leader in clinical medicine and a pioneer in science. In other words, the reasons for change were inconspicuous. Time was when the whole of medical education was in the hands of the working leaders of the profession, and grand was our progression in those simpler days. But as our learning became more intense as well as more far-ranging, the preliminary and intermediate subjects passed into the hands of teachers with special equipment, the instruction in the principles of medicine and surgery being left to the honorary staffs of the voluntary hospitals. These men earned their living by private practice, carried on in time that was already heavily pledged to gratuitous labour in the wards. Scientific research and systematic teaching of the students were prosecuted, in addition to their duties to private and hospital patients, and with results of which all may be proud. But the strain was obviously too great, while in election to the honorary staff capacity or inclination for teaching carried but little weight. Nor was the appointment of the clinical teachers under the control of the medical school attached to the hospital, so that every teacher was a law to himself, and the whole organisation was at the mercy of the less conscientious members of the staff. That these were few proves the rectitude and enthusiasm of a large number of men, but for some time it has been known that a more efficacious and orderly scheme, one less dependent upon personal sacrifice, must be found to supplement the clinical education of the student. The institution of clinical units should bring the education of the student up to the level of the progressive learning which has now to be dealt with.

The appointment of whole-time or part-time professors selected for their clinical and teaching power, and proved capacity for research, is supplemented by suitable assistants, and the professors will arrive by detailed arrangement at close relation with the student; it is designed thus to maintain the traditional features of the British system of clinical training, while correcting defects that have arisen in that system as our science has progressed. The student's appointments and the order in which he takes various parts of the clinical curriculum differ with each medical school, and a representative of THE LANCET recently visited the five medical schools which have adopted the clinical unit system in order to learn the details of its interpretation. These details will shortly be published in our columns, when it will be seen that each school has incorporated a professorial unit without in any way losing its special characteristics. In each of the five schools which have established clinical units special rooms and laboratories have been allocated or are to be constructed for research, and the assistant directors as well as the directors will have opportunities of investigating patients under their own charge as in-patients. In every case it is proposed eventually to institute research studentships, so that promising juniors may be trained, after qualification, in the methods of research. The arrangements for research will vary with the individual bias of the investigators and, moreover, have no direct connexion with the undergraduate, except in so far as he is being taught by men who are keenly alive to the importance of discovering a scientific basis for medical practice. For graduate and undergraduate alike the institution of clinical units marks a great stride forward in medical training.

RATES OF PENSION.

Compulsory retirement will be as follows:—

(i) Surgeon Rear-Admirals retire at the age of 60 with retired pay at the rate of £900 per annum plus £22 per annum for each year's service over 27 years counting for retired pay, subject to a maximum rate of £1010 per annum. If, however, less than 27 years' service counting towards retired pay is rendered, a deduction of £22 per annum is made for each full year wanting to complete that period, subject to a minimum of £790 per annum.

(ii) Surgeon-Captains retire at the age of 55. Maximum retired pay, £900.

(iii) Surgeon-Commanders retire at the age of 50. Maximum retired pay, £600.

(iv) Surgeon Lieutenant-Commanders and Lieutenants retire at the age of 45. Maximum retired pay, £450.

Subject to these maxima, the rates of retired pay for Surgeon-Captains, Surgeon-Commanders, Surgeon Lieutenant-Commanders, and Surgeon-Lieutenants are as follows:—

Age on retirement.	Retired pay.	Period of service (years) counting towards retired pay.	(A)		Age on retirement.	Retired pay.	Period of service (years) counting towards retired pay.	(A)	
			Addition.	Deduction.				Addition.	Deduction.
£	(p.a.)		£	(p.a.)	£	(p.a.)		£	(p.a.)
55	790	24	22	15	47	562	20	15	15
54	765	24	22	15	45	525	20	15	15
53	742	23	22	15	45	478	19	15	15
52	720	23	22	15	44	450	19	15	15
51	697	22	22	15	43	422	18	15	15
50	675	22	15	15	42	375	18	15	15
49	637	21	15	15	41	337	17	15	15
48	600	21	15	15	40	300	17	15	15

(P. a.) = per annum.

(A) Addition for each full year's service in excess of that specified in column 3 or deduction for each full year wanting to complete that period of service—addition or deduction limited to five years in each case.

ARMY MEDICAL SERVICE.

THE recent alterations in the conditions of service in the Royal Army Medical Corps, which constituted, as we said at the time, the greatest reform that has taken place in that Service for a generation, have well fulfilled their promise. For many reasons which are obvious and have been detailed on previous occasions, the Service can be thoroughly recommended to young medical practitioners. The Regulations should be obtained from the Army Medical Department, and carefully studied.

These are the things which the man who contemplates joining the Service should bear in mind. The rates of pay and allowances are good; the chances of seeing the world and the opportunities for post-graduate study are generous, and the work is nowadays varied, responsible, and interesting from a scientific point of view. At certain periods in his career the young officer is relieved from all other duties from six to nine months for the purpose of post-graduate study. During this period he is on full pay and the fees for his courses of instruction are paid by the State. His time is devoted to post-graduate work, and the leading clinical and scientific institutions are co-operating to secure that this post-graduate work shall be real and fruitful. At the same time in districts where the privilege would be of the most practical value opportunities are forthcoming for young officers to attend the clinical practice of large local general hospitals.

By a Royal Warrant issued in September, 1919, medical and combatant officers were placed on the same footing as regards retired pay, and the fact that medical officers enter the Service after a long and expensive training some five years later in life than combatant officers was overlooked. This inequality of treatment has now been rectified, with the result that a medical officer of 20 years' service or over gets £75 per annum more pension than a combatant officer with the same number of years service.

Once again let us deal with the most frequently repeated criticism of the Service—namely, that administration eternally takes the *pas* of science. The Directorates in Pathology and Hygiene which were recently created in the R.A.M.C., and which we may say have proved

marked success, form a complete answer to such criticism, however just it was in the past. This scheme of creating Directorates permits specially selected men to rise from all ranks to Major-General on the strength of their scientific work. Hitherto, a few notable men being excepted, the rule in the R.A.M.C. has been that, whatever a man's qualifications or abilities, on attaining the rank of Lieutenant-Colonel, he must be prepared to go off into administrative work and leave his scientific duties to his juniors. If he preferred to remain working in bacteriology, in preventive medicine and hygiene, or in tropical diseases, for example, he could do so, but, except in extraordinarily fortunate circumstances for himself, he would find that his devotion to science had cost him all chances of promotion in his Service, promotion being reserved for the administrative billets. The arrangement was wasteful as well as mortifying. How could the younger men be expected to preserve their interest in their scientific studies if such was the outcome? And how could their seniors be expected to remain in touch with the scientific developments in whose working out they no longer had any personal share? This now has all been changed, largely owing to the work of Sir John Goodwin, Director-General of the Service, with the assistance of Sir William Leishman and Sir William Horrocks. The change has its expression in these Directorates. Time was found during the last year of the war to prepare a scheme of reform, and to-day all up to and including the rank of Lieutenant-Colonel can draw specialist pay and hold appointments carrying allowances. The following substitutions for Articles 360 and 361 in the Royal Warrant for Pay Appointment, Promotion, and Non-effective Pay indicate the position. (See THE LANCET, Dec. 27th, 1919.)

Additional Pay and Charge Pay for Officers of the R.A.M.C.

The alterations, made under Army Order 411, 1919, became effective as from Jan. 1st, 1920:—

(1) In Article 360, for "officer under the rank of Lieutenant-colonel appointed by Our Army Council as specialist 2s. 6d. a day," the following is substituted:—

"Officer not above the rank of lieutenant-colonel, while acting as specialist in a post considered by Our Army Council to merit the grant of additional pay, according to subjects or groups of subjects as under, within a limit of 5s. a day:—

Operative Surgery, advanced; Medicine; Ophthalmology; Gynecology and Midwifery; Dermatology, including Venereal Disease, 5s. daily.

Otology, Laryngology, and Rhinology; Radiology; Anaesthetics; Mental Diseases; Hygiene; Pathology; subjects other than above, at the discretion of Our Army Council, 2s. 6d. daily.

Officers granted temporary higher rank while holding appointments in the services of hygiene and pathology will not be eligible for additional pay as specialists while holding such temporary rank."

(2) The following is substituted for Article 361 (a):—

"(a) Officer in charge of a hospital.—If the number of equipped beds, as certified by the Deputy Director of Medical Services, exceeds—

50 beds 2s. 6d. daily. | 300 beds 7s. 6d. daily.
150 5s. 0d. .. | 500 10s. 0d. ..

Officer in charge of a medical or surgical division of a general hospital with not less than 300 beds—half the above rates."

Further, an officer, graded as a specialist, and appointed to the charge of a medical or surgical division of a general hospital may be allowed to retain his additional pay and to draw the rate of charge pay laid down for the officer in charge of a medical or surgical division of a general hospital, provided that the total of additional and charge pay so drawn does not exceed the rate of charge pay drawn by the officer in charge of the hospital. With this exception charge pay and additional pay as specialist will not be issuable concurrently. It may be here pointed out that the distinction between scientific and administrative work is largely verbal. Take the conduct of a large hospital—is it possible to separate the scientific routine which is designed to ensure progressive therapeutics from the administrative work which provides and maintains the premises and service, and selects and oversees the personnel?

Under the conditions enumerated the possibilities for good workers is very great in the R.A.M.C.; they will attain to positions of proper trust and emolument by scientific work. This should much improve recruiting among the officers of the R.A.M.C. But there will almost certainly follow arrangements by which all special medical service will receive higher consideration in the Corps. Not only is there in the work of the Army Medical Department scope for original labour and research in tropical disease, in preventive medicine, and in bacteriology, as well as in the vast clinical field open to the specialist

in medicine, surgery, or gynaecology, in venereal disease, in ophthalmology, and so on, but it is proposed to develop a scheme whereby child welfare shall be undertaken systematically by the R.A.M.C. A scheme of this sort is already running successfully at Aldershot, and we see in this direction a fine opening for preventive medicine, and one which should bring the officers of the R.A.M.C. into touch with the soldiers in a valuable and intimate manner.

Lastly, we may remark that the appointment of a Consultant in Surgery, with the duty to visit all commands and advise the Director-General from inspection on the spot with regard to the conduct of hospitals, the scientific work in them, and the qualities of the personnel, should ensure a high standard of performance, if only because of the satisfactory feeling that good work will not by accident remain unnoticed. The present holder of the post is Colonel E. M. Pilcher, recently professor of surgery in the Royal Army Medical College.

RATES OF PAY AND PENSION.

The following table shows the

Total Emoluments: Royal Army Medical Corps.

Appointment.	Pay.	Rations.	Servant.	Married.			Un-married.			Total per annum.	
				Lodging.	Fuel and light (average).	Furniture allowance.	Lodging.	Fuel and light (average).	Furniture allowance.	Married.	Unmarried.
Lieutenant ...	£ 1 2 0	s. 21	d. 20	3 6	1 0	2 0	2 0	0 10	0 10	£ 594	£ 532
Captain ...	1 7 0	21	20	4 6	2 0	2 0	2 0	1 2	0 10	722	643
Captain—											
After 5 years...	1 7 6	21	20	4 6	2 0	2 0	3 0	1 2	0 10	731	652
" 6 years...	1 8 0	21	20	4 6	2 0	2 0	3 0	1 2	0 10	740	661
" 10 years...	1 11 0	21	20	4 6	2 0	2 0	3 0	1 2	0 10	795	716
Major ...	1 15 0	21	20	4 6	2 0	2 0	4 0	1 7	0 10	865	815
Major, after 15 years ...	2 0 0	21	20	4 6	2 0	2 0	4 0	1 7	0 10	959	907
Lieutenant-Colonel ...	2 10 0	21	20	4 6	2 0	2 0	4 6	1 7	0 10	1142	1098
Lieutenant-Colonel, after 20 years ...	2 12 6	21	20	4 6	2 0	2 0	4 6	1 7	0 10	1187	1144
Lieutenant-Colonel, after 25 years ...	2 15 0	21	20	4 6	2 0	2 0	4 6	1 7	0 10	1233	1189
Colonel ...	3 5 0	21	20	5 6	2 10	2 0	5 6	1 10	0 10	1449	1395
Major-General ...	4 15 0	21	40	11 0	3 7	2 0	11 0	2 7	0 10	2147	2092

Charge pay (2s. 6d.-10s. per day) and specialist's pay (2s. 6d.-5s. per day)—i.e., from £45-£180 per annum—in addition for a considerable percentage of officers.

Retirement and Retired Pay.

The following are the rates of pension and retired pay:—

- Retired pay will consist of two parts: (a) a service element based on the officer's total service; (b) a rank element for the rank from which the officer retires. An officer with less than 20 complete years' service will not be eligible for retired pay.
- The scale will be as follows:—

- Service element.—£15 = year for each completed year of service.
- Rank element.—

Rank from which retired.	After completing 1 year's service in the rank.	After completing each additional year's service.	Maximum rank element.
Major ...	£ 12	£ 12	£ 120
Lieutenant-Colonel ...	150	30	240
Colonel ...	290	50	390
Major-General ...	440	50	540
Lieutenant-General ...	590	50	690
General ...	740	50	840

The retired pay of an officer retiring with less than one complete year's service in the rank from which he retires will be assessed as though he had retired from the rank below.

Maximum rates of retired pay (a) and (b) together:—

Captain and Subaltern ...	£ 300	Colonel ...	£ 800
Major ...	450	Major-General ...	1000
Lieutenant-Colonel ...	600	Lieutenant-General ...	1200

Officers with 8½ and less than 20 years' service may be permitted to retire with a gratuity varying from £1000 to £2500.

INDIAN MEDICAL SERVICE.

THE Indian Medical Service differs from all the other State Services in that it combines the attractions of a military and a civil career. It is primarily a military service, and all officers on first landing in India are detailed for service with Indian troops in Indian military station hospitals. After a period of military duty, which before the war varied from four to eight years, the majority of officers elected for and were transferred to the civil side. While in civil employ they constitute the war reserve for the Indian Army. During the great war practically all officers not occupying administrative posts or filling essential civil duties were called up for military service.

The possibilities of medical and surgical work and the opportunities for research in all directions which the Service affords have always proved of great attraction, though in recent years the Service has lost its former popularity in the medical schools, and for some time prior to the war competition among highly qualified European candidates was not keen. Under the changed conditions in India the pay and emoluments were insufficient, and the terms of service were out of date. The whole constitution and organisation of the Service has recently been under examination by a Medical Services Committee. The report of this Committee has not yet been published, but it is understood that its recommendations are such as seem likely to restore the Indian Medical Service to its former high position and prestige among the State Services. Meanwhile, the pay, pensions, and leave reserve have been substantially increased, whilst questions relating to furlough pay, passages, status of administrative officers are in process of satisfactory settlement. The Station Hospital system has been introduced and command allowances and second in command allowances have been granted for charge of hospitals. These reforms, now happily ensured, have completely altered the outlook. Young medical practitioners can now join the I.M.S. and be secure of a competency from the day they receive their commissions. We can therefore recommend the Service to them. The British Medical Association is using its best endeavours to stimulate and help in recruiting.

A great career is open to any young medical man with the proper qualifications and keen on his profession. During the first few years while on military duty the young officer becomes acquainted with and is trained in Indian military medical organisation. He acquires experience in dealing with the different races and castes which comprise the Indian Army. He learns the language and customs of the country. He familiarises himself with the practice of tropical medicine and surgery, and has leisure to pursue his further studies with time for recreation and sport in any direction his inclination may dictate. During these years he can make up his mind as to which branch of professional skill he wishes to devote special attention, and whether he is desirous of remaining in military employ throughout his service. Specialist appointments are available on both the military and civil sides.

On the civil side, and the majority of officers are civil surgeons in charge of districts and the civil district hospitals, the work is heavy and interesting, the bulk of it being surgery. There is no country in the world which offers better opportunity for the young surgeon once he has acquired the confidence and esteem of the inhabitants. Private practice is permitted, but it may be stated at once that the emoluments from this source, except in the Presidency or large towns, are generally negligible. Nevertheless, with the pay as it now exists, plus certain minor allowances, the civil surgeon is in a position to live reasonably in his earlier years, and can confidently expect, should his professional qualifications and reputation merit his preference, to be selected for the higher professional posts where a lucrative practice is obtainable. I.M.S. officers are eligible for the professorships at the Medical Colleges in Calcutta, Bombay, Madras, Lahore, and Lucknow in the various subjects comprising the medical curriculum. The bacteriological, sanitary and chemical examinations, work as alienists, and in the jail departments open out careers of a truly varied and valuable kind for those who wish to devote themselves mainly to scientific research or specialist work. The bacteriological laboratories and Pasteur institutes at Kasauli, Bombay, Coonoor,

Shillong, and Rangoon are splendidly equipped with provision for research workers. In addition to the scales of pay laid down, allowances are granted for service in the above departments.

Under the study leave rules officers are entitled during their service to a year's study leave in England. This period counts as duty, and is in addition to furlough. It is granted on the basis of one month's study leave for each year's active service up to a total maximum of 12 months. Most officers take it in two periods of 6 months each, and add it on to their ordinary furlough. During the period of study leave they are at liberty to pursue courses of approved study in any country. They receive furlough pay plus an additional lodging allowance of 12s. a day. The opportunity thus provided for continuing post-graduate studies for a period of six months twice in his service is invaluable both to the individual and the State.

Accelerated promotion of six months to the rank of major is granted to officers for approved study or for obtaining the higher medical qualifications.

As regards leave, the Secretary of State has undertaken to increase the leave reserve to 25 per cent. and maintain the 2½ per cent. study leave in addition. These percentages when worked up to are considered ample.

The Secretary of State has further undertaken that officers of the I.M.S. on the military side will receive the same concessions as regards passages as combatant officers, while officers on the civil side will receive the same concessions, if any, as may be granted to other officers in employ.

The rates of basic pay and pensions are given below :—

NEW RATES OF PAY.
